5237 Comparing Nearest Neighbors with and without Neighborhood Components
Analysis
An example comparing nearest neighbors classification with and without Neighborhood Components Analysis
It will plot the class decision boundaries given by a Nearest Neighbors classifier when using the Euclidean distance
on the original features versus using the Euclidean distance after the transformation learned by Neighborhood Com
ponents Analysis The latter aims to find a linear transformation that maximises the stochastic nearest neighbor
classification accuracy on the training set

5238 Dimensionality Reduction with Neighborhood Components Analysis
Sample usage of Neighborhood Components Analysis for dimensionality reduction
This example compares different linear dimensionality reduction methods applied on the Digits data set The data
523 Nearest Neighbors 1331

set contains images of digits from 0 to 9 with approximately 180 samples of each class Each image is of dimension 8x8 64 and is reduced to a twodimensional data point
Principal Component Analysis PCA applied to this data identifies the combination of attributes principal compo nents or directions in the feature space that account for the most variance in the data Here we plot the different samples on the 2 first principal components
Linear Discriminant Analysis LDA tries to identify attributes that account for the most variance between classes In particular LDA in contrast to PCA is a supervised method using known class labels
Neighborhood Components Analysis NCA tries to find a feature space such that a stochastic nearest neighbor algo rithm will give the best accuracy Like LDA it is a supervised method
One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension

5239 Kernel Density Estimate of Species Distributions
This shows an example of a neighborsbased query in particular a kernel density estimate on geospatial data using
a Ball Tree built upon the Haversine distance metric – ie distances over points in latitudelongitude The dataset
523 Nearest Neighbors 1335

is provided by Phillips et al 2006 If available the example uses basemap to plot the coast lines and national boundaries of South America
This example does not perform any learning over the data see Species distribution modeling for an example of classification based on the attributes in this dataset It simply shows the kernel density estimate of observed data points in geospatial coordinates
The two species are
• “Bradypus variegatus” the Brownthroated Sloth
• “Microryzomys minutus” also known as the Forest Small Rice Rat a rodent that lives in Peru Colombia Ecuador Peru and Venezuela

52311 Simple 1D Kernel Density Estimation
This example uses the sklearnneighborsKernelDensity class to demonstrate the principles of Kernel Density Estimation in one dimension
The first plot shows one of the problems with using histograms to visualize the density of points in 1D Intuitively a histogram can be thought of as a scheme in which a unit “block” is stacked above each point on a regular grid As the top two panels show however the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution If we instead center each block on the point it represents we get the estimate shown in the bottom left panel This is a kernel density estimation with a “top hat” kernel This idea can be generalized to other kernel shapes the bottomright panel of the first figure shows a Gaussian kernel density estimate over the same distribution
Scikitlearn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure through the sklearnneighborsKernelDensity estimator The available kernels are shown in the second figure of this example
The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension Though this example uses 1D distributions kernel density estimation is easily and efficiently extensible to higher dimensions as well

5241 Visualization of MLP weights on MNIST
Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior For example if weights look unstructured maybe some were not used at all or if very large coefficients exist maybe regularization was too low or the learning rate too high

This example shows how to plot some of the first layer weights in a MLPClassifier trained on the MNIST dataset The input data consists of 28x28 pixel handwritten digits leading to 784 features in the dataset Therefore the first layer weight matrix have the shape 784 hiddenlayersizes0 We can therefore visualize a single column of the weight matrix as a 28x28 pixel image
To make the example run faster we use very few hidden units and train only for a very short time Training longer would result in weights with a much smoother spatial appearance

5242 Restricted Boltzmann Machine features for digit classification
For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background like handwritten digit recognition the Bernoulli Restricted Boltzmann machine model BernoulliRBM can perform effective nonlinear feature extraction
In order to learn good latent representations from a small dataset we artificially generate more labeled data by per turbing the training data with linear shifts of 1 pixel in each direction
This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a LogisticRegression classifier The hyperparameters of the entire model learning rate hidden layer size regu larization were optimized by grid search but the search is not reproduced here because of runtime constraints Logistic regression on raw pixel values is presented for comparison The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy

5243 Varying regularization in Multilayer Perceptron
A comparison of different values for regularization parameter ‘alpha’ on synthetic datasets The plot shows that different alphas yield different decision functions
Alpha is a parameter for regularization term aka penalty term that combats overfitting by constraining the size of the weights Increasing alpha may fix high variance a sign of overfitting by encouraging smaller weights resulting in a decision boundary plot that appears with lesser curvatures Similarly decreasing alpha may fix high bias a sign of underfitting by encouraging larger weights potentially resulting in a more complicated decision boundary

5244 Compare Stochastic learning strategies for MLPClassifier
This example visualizes some training loss curves for different stochastic learning strategies including SGD and
Adam Because of timeconstraints we use several small datasets for which LBFGS might be more suitable The
general trend shown in these examples seems to carry over to larger datasets however
Note that those results can be highly dependent on the value of learningrateinit

5252 Using KBinsDiscretizer to discretize continuous features
The example compares prediction result of linear regression linear model and decision tree tree based model with and without discretization of realvalued features
As is shown in the result before discretization linear model is fast to build and relatively straightforward to interpret but can only model linear relationships while decision tree can build a much more complex model of the data One way to make linear model more powerful on continuous data is to use discretization also known as binning In the example we discretize the feature and onehot encode the transformed data Note that if the bins are not reasonably wide there would appear to be a substantially increased risk of overfitting so the discretizer parameters should usually be tuned under cross validation
After discretization linear regression and decision tree make exactly the same prediction As features are constant within each bin any model must predict the same value for all points within a bin Compared with the result before

discretization linear model become much more flexible while decision tree gets much less flexible Note that bin
ning features generally has no beneficial effect for treebased models as these models can learn to split up the data

5253 Demonstrating the different strategies of KBinsDiscretizer
This example presents the different strategies implemented in KBinsDiscretizer
• ‘uniform’ The discretization is uniform in each feature which means that the bin widths are constant in each dimension
• quantile’ The discretization is done on the quantiled values which means that each bin has approximately the same number of samples
• ‘kmeans’ The discretization is based on the centroids of a KMeans clustering procedure
The plot shows the regions where the discretized encoding is constant

scikitlearn user guide Release 0213
5254 Importance of Feature Scaling
Feature scaling through standardization or Zscore normalization can be an important preprocessing step for many machine learning algorithms Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one
While many algorithms such as SVM Knearest neighbors and logistic regression require features to be normalized intuitively we can think of Principle Component Analysis PCA as being a prime example of when normalization is important In PCA we are interested in the components that maximize the variance If one component eg human height varies less than another eg weight because of their respective scales meters vs kilos PCA might determine that the direction of maximal variance more closely corresponds with the ‘weight’ axis if those features are not scaled As a change in height of one meter can be considered much more important than the change in weight of one kilogram this is clearly incorrect
To illustrate this PCA is performed comparing the use of data with StandardScaler applied to unscaled data The results are visualized and a clear difference noted The 1st principal component in the unscaled set can be seen It can be seen that feature 13 dominates the direction being a whole two orders of magnitude above the other features This is contrasted when observing the principal component for the scaled version of the data In the scaled version the orders of magnitude are roughly the same across all the features
The dataset used is the Wine Dataset available at UCI This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure ie alcohol content and malic acid
The transformed data is then used to train a naive Bayes classifier and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version

5255 Map data to a normal distribution
This example demonstrates the use of the BoxCox and YeoJohnson transforms through preprocessing PowerTransformer to map data from various distributions to a normal distribution
The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired Below are examples of BoxCox and YeoJohnwon applied to six different probability distributions Lognormal Chisquared Weibull Gaussian Uniform and Bimodal
Note that the transformations successfully map the data to a normal distribution when applied to certain datasets but are ineffective with others This highlights the importance of visualizing the data before and after transformation
Also note that even though BoxCox seems to perform better than YeoJohnson for lognormal and chisquared distributions keep in mind that BoxCox does not support inputs with negative values
For comparison we also add the output from preprocessingQuantileTransformer It can force any arbitrary distribution into a gaussian provided that there are enough training samples thousands Because it is a nonparametric method it is harder to interpret than the parametric ones BoxCox and YeoJohnson
On “small” datasets less than a few hundred points the quantile transformer is prone to overfitting The use of the power transform is then recommended

5256 Feature discretization
A demonstration of feature discretization on synthetic classification datasets Feature discretization decomposes each
feature into a set of bins here equally distributed in width The discrete values are then onehot encoded and given to
a linear classifier This preprocessing enables a nonlinear behavior even though the classifier is linear
525 Preprocessing 1373

On this example the first two rows represent linearly nonseparable datasets moons and concentric circles while the third is approximately linearly separable On the two linearly nonseparable datasets feature discretization largely increases the performance of linear classifiers On the linearly separable dataset feature discretization decreases the performance of linear classifiers Two nonlinear classifiers are also shown for comparison
This example should be taken with a grain of salt as the intuition conveyed does not necessarily carry over to real datasets Particularly in highdimensional spaces data can more easily be separated linearly Moreover using feature discretization and onehot encoding increases the number of features which easily lead to overfitting when the number of samples is small
The plots show training points in solid colors and testing points semitransparent The lower right shows the classifi cation accuracy on the test set

5257 Compare the effect of different scalers on data with outliers
Feature 0 median income in a block and feature 5 number of households of the California housing dataset have very different scales and contain some very large outliers These two characteristics lead to difficulties to visualize the data and more importantly they can degrade the predictive performance of many machine learning algorithms Unscaled data can also slow down or even prevent the convergence of many gradientbased estimators
Indeed many estimators are designed with the assumption that each feature takes values close to zero or more im portantly that all features vary on comparable scales In particular metricbased and gradientbased estimators often assume approximately standardized data centered features with unit variances A notable exception are decision treebased estimators that are robust to arbitrary scaling of the data
This example uses different scalers transformers and normalizers to bring the data within a predefined range
Scalers are linear or more precisely affine transformers and differ from each other in the way to estimate the param eters used to shift and scale each feature
QuantileTransformer provides nonlinear transformations in which distances between marginal outliers and inliers are shrunk PowerTransformer provides nonlinear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness
Unlike the previous transformations normalization refers to a per sample transformation instead of a per feature transformation
The following code is a bit verbose feel free to jump directly to the analysis of the results

Original data
Each transformation is plotted showing two transformed features with the left plot showing the entire dataset and the right zoomedin to show the dataset without the marginal outliers A large majority of the samples are compacted to a specific range 0 10 for the median income and 0 6 for the number of households Note that there are some marginal outliers some blocks have more than 1200 households Therefore a specific preprocessing can be very beneficial depending of the application In the following we present some insights and behaviors of those preprocessing methods in the presence of marginal outliers
makeplot0
525 Preprocessing 1381

scikitlearn user guide Release 0213
StandardScaler
StandardScaler removes the mean and scales the data to unit variance However the outliers have an influence when computing the empirical mean and standard deviation which shrink the range of the feature values as shown in the left figure below Note in particular that because the outliers on each feature have different magnitudes the spread of the transformed data on each feature is very different most of the data lie in the 2 4 range for the transformed median income feature while the same data is squeezed in the smaller 02 02 range for the transformed number of households
StandardScaler therefore cannot guarantee balanced feature scales in the presence of outliers
makeplot1
MinMaxScaler
MinMaxScaler rescales the data set such that all feature values are in the range 0 1 as shown in the right panel below However this scaling compress all inliers in the narrow range 0 0005 for the transformed number of households
AsStandardScaler MinMaxScaler is very sensitive to the presence of outliers
makeplot2
1382 Chapter 5 Examples

scikitlearn user guide Release 0213
MaxAbsScaler
MaxAbsScaler differs from the previous scaler such that the absolute values are mapped in the range 0 1 On positive only data this scaler behaves similarly to MinMaxScaler and therefore also suffers from the presence of large outliers
makeplot3
RobustScaler
Unlike the previous scalers the centering and scaling statistics of this scaler are based on percentiles and are therefore not influenced by a few number of very large marginal outliers Consequently the resulting range of the transformed feature values is larger than for the previous scalers and more importantly are approximately similar for both features most of the transformed values lie in a 2 3 range as seen in the zoomedin figure Note that the outliers themselves are still present in the transformed data If a separate outlier clipping is desirable a nonlinear transformation is required see below
makeplot4
PowerTransformer
PowerTransformer applies a power transformation to each feature to make the data more Gaussianlike Cur
525 Preprocessing 1383

scikitlearn user guide Release 0213
rentlyPowerTransformer implements the YeoJohnson and BoxCox transforms The power transform finds
the optimal scaling factor to stabilize variance and mimimize skewness through maximum likelihood estimation By
defaultPowerTransformer also applies zeromean unit variance normalization to the transformed output Note
that BoxCox can only be applied to strictly positive data Income and number of households happen to be strictly
positive but if negative values are present the YeoJohnson transformed is to be preferred
makeplot5
makeplot6
•
•
QuantileTransformer Gaussian output
QuantileTransformer has an additional outputdistribution parameter allowing to match a Gaussian
distribution instead of a uniform distribution Note that this nonparametetric transformer introduces saturation arti
facts for extreme values
makeplot7

scikitlearn user guide Release 0213
QuantileTransformer uniform output
QuantileTransformer applies a nonlinear transformation such that the probability density function of each feature will be mapped to a uniform distribution In this case all the data will be mapped in the range 0 1 even the outliers which cannot be distinguished anymore from the inliers
AsRobustScaler QuantileTransformer is robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation on held out data But contrary to RobustScaler QuantileTransformer will also automatically collapse any outlier by setting them to the a priori defined range boundaries 0 and 1
makeplot8
Normalizer
TheNormalizer rescales the vector for each sample to have unit norm independently of the distribution of the samples It can be seen on both figures below where all samples are mapped onto the unit circle In our example the two selected features have only positive values therefore the transformed data only lie in the positive quadrant This would not be the case if some original features had a mix of positive and negative values

5263 Label Propagation digits Demonstrating performance
This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels
The handwritten digit dataset has 1797 total points The model will be trained using all points but only 30 will be labeled Results in the form of a confusion matrix and a series of metrics over each class will be very good
At the end the top 10 most uncertain predictions will be shown

5264 Label Propagation digits active learning
Demonstrates an active learning technique to learn handwritten digits using label propagation
We start by training a label propagation model with only 10 labeled points then we select the top five most uncertain points to label Next we train with 15 labeled points original 10 5 new ones We repeat this process four times to have a model trained with 30 labeled examples Note you can increase this to label more than 30 by changing maxiterations Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique
A plot will appear showing the top 5 most uncertain digits for each iteration of training These may or may not contain mistakes but we will train the next model with their true labels

52711 Plot different SVM classifiers in the iris dataset
Comparison of different linear SVM classifiers on a 2D projection of the iris dataset We only consider the first 2 features of this dataset
• Sepal length
• Sepal width
This example shows how to plot the decision surface for four SVM classifiers with different kernels
The linear models LinearSVC andSVCkernellinear yield slightly different decision boundaries
This can be a consequence of the following differences
•LinearSVC minimizes the squared hinge loss while SVC minimizes the regular hinge loss
•LinearSVC uses the OnevsAll also known as OnevsRest multiclass reduction while SVC uses the One vsOne multiclass reduction
Both linear models have linear decision boundaries intersecting hyperplanes while the nonlinear kernel models polynomial or Gaussian RBF have more flexible nonlinear decision boundaries with shapes that depend on the kind of kernel and its parameters

Note while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power be aware that those intuitions don’t always generalize to more realistic high dimensional problems

52712 Scaling the regularization parameter for SVCs
The following example illustrates the effect of scaling the regularization parameter when using Support Vector Ma
chines forclassification For SVC classification we are interested in a risk minimization for the equation
□Σ
□1□ℒ□□□ □□
 □
where
•□is used to set the amount of regularization
•ℒis aloss function of our samples and our model parameters
•
is apenalty function of our model parameters
If we consider the loss function to be the individual error per sample then the datafit term or the sum of the error for
each sample will increase as we add more samples The penalization term however will not increase
When using for example cross validation to set the amount of regularization with C there will be a different amount
of samples between the main problem and the smaller problems within the folds of the cross validation
Since our loss function is dependent on the amount of samples the latter will influence the selected value of
C The question that arises is How do we optimally adjust C to account for the different
amount of training samples
The figures below are used to illustrate the effect of scaling our Cto compensate for the change in the number of
samples in the case of using an l1penalty as well as the l2penalty
l1penalty case
In thel1case theory says that prediction consistency ie that under given hypothesis the estimator learned predicts
as well as a model knowing the true distribution is not possible because of the bias of the l1 It does say however
that model consistency in terms of finding the right set of nonzero parameters as well as their signs can be achieved
by scalingC1
l2penalty case
The theory says that in order to achieve prediction consistency the penalty parameter should be kept constant as the
number of samples grow

Simulations
The two figures below plot the values of Con thexaxis and the corresponding crossvalidation scores on the yaxis for several different fractions of a generated dataset
In thel1penalty case the crossvalidationerror correlates best with the testerror when scaling our Cwith the number of samples n which can be seen in the first figure
For thel2penalty case the best result comes from the case where Cis not scaled
Note
Two separate datasets are used for the two different plots The reason behind this is the l1case works better on sparse data while l2is better suited to the nonsparse case

52713 RBF SVM parameters
This example illustrates the effect of the parameters gamma andCof the Radial Basis Function RBF kernel SVM
Intuitively the gamma parameter defines how far the influence of a single training example reaches with low values meaning ‘far’ and high values meaning ‘close’ The gamma parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors
TheCparameter trades off correct classification of training examples against maximization of the decision function’s margin For larger values of C a smaller margin will be accepted if the decision function is better at classifying all training points correctly A lower Cwill encourage a larger margin therefore a simpler decision function at the cost of training accuracy In other words‘‘C‘‘ behaves as a regularization parameter in the SVM
The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes binary classification Note that this kind of plot is not possible to do for problems with more features or target classes
The second plot is a heatmap of the classifier’s crossvalidation accuracy as a function of Candgamma For this example we explore a relatively large grid for illustration purposes In practice a logarithmic grid from 10−3to103 is usually sufficient If the best parameters lie on the boundaries of the grid it can be extended in that direction in a subsequent search
Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye
The behavior of the model is very sensitive to the gamma parameter If gamma is too large the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with Cwill be able to prevent overfitting
Whengamma is very small the model is too constrained and cannot capture the complexity or “shape” of the data The region of influence of any selected support vector would include the whole training set The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes
For intermediate values we can see on the second plot that good models can be found on a diagonal of Candgamma Smooth models lower gamma values can be made more complex by increasing the importance of classifying each point correctly larger Cvalues hence the diagonal of good performing models
Finally one can also observe that for some intermediate values of gamma we get equally performing models when C becomes very large it is not necessary to regularize by enforcing a larger margin The radius of the RBF kernel alone acts as a good structural regularizer In practice though it might still be interesting to simplify the decision function with a lower value of Cso as to favor models that use less memory and that are faster to predict
We should also note that small differences in scores results from the random splits of the crossvalidation procedure Those spurious variations can be smoothed out by increasing the number of CV iterations nsplits at the expense of compute time Increasing the value number of Crange andgammarange steps will increase the resolution of the hyperparameter heat map

 Load and prepare data set

 dataset for grid search
iris  loadiris
X  irisdata
y  iristarget
 Dataset for decision function visualization we only keep the first two
 features in X and subsample the dataset to keep only 2 classes and
 make it a binary classification problem
X2d  X 2
X2d  X2dy  0
y2d  yy  0
y2d  1
 It is usually a good idea to scale the data for SVM training
 We are cheating a bit in this example in scaling all of the data
 instead of fitting the transformation on the training set and
 just applying it on the test set
scaler  StandardScaler
X  scalerfittransformX
X2d  scalerfittransformX2d

 Train classifiers

 For an initial search a logarithmic grid with basis
 10 is often helpful Using a basis of 2 a finer
 tuning can be achieved but at a much higher cost

5282 Clustering text documents using kmeans
This is an example showing how the scikitlearn can be used to cluster documents by topics using a bagofwords approach This example uses a scipysparse matrix to store the features instead of standard numpy arrays
Two feature extraction methods can be used in this example
• TfidfVectorizer uses a inmemory vocabulary a python dict to map the most frequent words to features indices and hence compute a word occurrence frequency sparse matrix The word frequencies are then reweighted using the Inverse Document Frequency IDF vector collected featurewise over the corpus
• HashingVectorizer hashes word occurrences to a fixed dimensional space possibly with collisions The word count vectors are then normalized to each have l2norm equal to one projected to the euclidean unitball which seems to be important for kmeans to work in high dimensional space
HashingVectorizer does not provide IDF weighting as this is a stateless model the fit method does nothing When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance
Two algorithms are demoed ordinary kmeans and its more scalable cousin minibatch kmeans
Additionally latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data
It can be noted that kmeans and minibatch kmeans are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset
This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets

such as text data Other measures such as Vmeasure and Adjusted Rand Index are information theoretic based eval
uation scores as they are only based on cluster assignments rather than distances hence not affected by the curse of
dimensionality
Note as kmeans is optimizing a nonconvex objective function it will likely end up in a local optimum Several runs
with independent random init might be necessary to get a good convergence

529 Decision Trees
Examples concerning the sklearntree module
Note Click here to download the full example code
5291 Decision Tree Regression
A 1D regression with decision tree
Thedecision trees is used to fit a sine curve with addition noisy observation As a result it learns local linear regres
sions approximating the sine curve
We can see that if the maximum depth of the tree controlled by the maxdepth parameter is set too high the
decision trees learn too fine details of the training data and learn from the noise ie they overfit

5292 Multioutput Decision Tree Regression
An example to illustrate multioutput regression with decision tree
Thedecision trees is used to predict simultaneously the noisy x and y observations of a circle given a single underlying
feature As a result it learns local linear regressions approximating the circle
We can see that if the maximum depth of the tree controlled by the maxdepth parameter is set too high the
decision trees learn too fine details of the training data and learn from the noise ie they overfit

5293 Plot the decision surface of a decision tree on the iris dataset
Plot the decision surface of a decision tree trained on pairs of features of the iris dataset
Seedecision tree for more information on the estimator
For each pair of iris features the decision tree learns decision boundaries made of combinations of simple thresholding rules inferred from the training samples
We also show the tree structure of a model built on all of the features

5294 Understanding the decision tree structure
The decision tree structure can be analysed to gain further insight on the relation between the features and the target to predict In this example we show how to retrieve
• the binary tree structure
• the depth of each node and whether or not it’s a leaf
• the nodes that were reached by a sample using the decisionpath method
• the leaf that was reached by a sample using the apply method
• the rules that were used to predict a sample
• the decision path shared by a group of samples
Out
The binary tree structure has 5 nodes and has the following tree structure
node0 test node go to node 1 if X 3 0800000011920929 else to node 2
node1 leaf node
node2 test node go to node 3 if X 2 4950000047683716 else to node 4
node3 leaf node

scikitlearn user guide Release 0213
node4 leaf node
Rules used to predict sample 0
decision id node 0 Xtest0 3 24 0800000011920929
decision id node 2 Xtest0 2 51 4950000047683716
The following samples 0 1 share the node 0 2 in the tree
It is 400 of all nodes
import numpy as np
from sklearnmodelselection import traintestsplit
from sklearndatasets import loadiris
from sklearntree import DecisionTreeClassifier
iris loadiris
X irisdata
y iristarget
Xtrain Xtest ytrain ytest traintestsplitX y randomstate0
estimator DecisionTreeClassifiermaxleafnodes3 randomstate0
estimatorfitXtrain ytrain
 The decision estimator has an attribute called tree which stores the entire
 tree structure and allows access to low level attributes The binary tree
 tree is represented as a number of parallel arrays The ith element of each
 array holds information about the node i Node 0 is the trees root NOTE
 Some of the arrays only apply to either leaves or split nodes resp In this
 case the values of nodes of the other type are arbitrary

 Among those arrays we have
  leftchild id of the left child of the node
  rightchild id of the right child of the node
  feature feature used for splitting the node
  threshold threshold value at the node

 Using those arrays we can parse the tree structure
nnodes estimatortreenodecount
childrenleft estimatortreechildrenleft
childrenright estimatortreechildrenright
feature estimatortreefeature
threshold estimatortreethreshold
 The tree structure can be traversed to compute various properties such
 as the depth of each node and whether or not it is a leaf
nodedepth npzerosshapennodes dtypenpint64
isleaves npzerosshapennodes dtypebool
stack 0 1 seed is the root node id and its parent depth
whilelenstack 0
nodeid parentdepth stackpop
529 Decision Trees 1455

```
nodedepthnodeid  parentdepth  1
 If we have a test node
ifchildrenleftnodeid  childrenrightnodeid
stackappendchildrenleftnodeid parentdepth  1
stackappendchildrenrightnodeid parentdepth  1
else
isleavesnodeid  True
printThe binary tree structure has snodes and has
the following tree structure

API REFERENCE
This is the class and function reference of scikitlearn Please refer to the full user guide for further details as the class and function raw specifications may not be enough to give full guidelines on their uses For reference on concepts repeated across the API see Glossary of Common Terms and API Elements
61sklearnbase Base classes and utility functions
Base classes for all estimators
611 Base classes
baseBaseEstimator Base class for all estimators in scikitlearn
baseBiclusterMixin Mixin class for all bicluster estimators in scikitlearn
baseClassifierMixin Mixin class for all classifiers in scikitlearn
baseClusterMixin Mixin class for all cluster estimators in scikitlearn
baseDensityMixin Mixin class for all density estimators in scikitlearn
baseRegressorMixin Mixin class for all regression estimators in scikitlearn
baseTransformerMixin Mixin class for all transformers in scikitlearn
sklearnbase BaseEstimator
classsklearnbase BaseEstimator
Base class for all estimators in scikitlearn
Notes
All estimators should specify all the parameters that can be set at the class level in their init as explicit keyword arguments no args orkwargs
Methods
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator

init selfargs kwargs
Initialize self See helptypeself for accurate signature
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnbaseBaseEstimator
•Inductive Clustering
•Column Transformer with Heterogeneous Data Sources
sklearnbase BiclusterMixin
classsklearnbase BiclusterMixin
Mixin class for all bicluster estimators in scikitlearn
Attributes
biclusters Convenient way to get row and column indicators together
Methods
getindices self i Row and column indices of the i’th bicluster
getshape self i Shape of the i’th bicluster
getsubmatrix self i data Returns the submatrix corresponding to bicluster i
init selfargs kwargs
Initialize self See helptypeself for accurate signature
biclusters
Convenient way to get row and column indicators together
Returns the rows andcolumns members
getindices selfi
Row and column indices of the i’th bicluster

Only works if rows andcolumns attributes exist
Parameters
iint The index of the cluster
Returns
rowind nparray dtypenpintp Indices of rows in the dataset that belong to the bicluster
colind nparray dtypenpintp Indices of columns in the dataset that belong to the biclus
ter
getshape selfi
Shape of the i’th bicluster
Parameters
iint The index of the cluster
Returns
shape int int Number of rows and columns resp in the bicluster
getsubmatrix selfidata
Returns the submatrix corresponding to bicluster i
Parameters
iint The index of the cluster
data array The data
Returns
submatrix array The submatrix corresponding to bicluster i
Notes
Works with sparse matrices Only works if rows andcolumns attributes exist
sklearnbase ClassifierMixin
classsklearnbase ClassifierMixin
Mixin class for all classifiers in scikitlearn
Methods
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
init selfargs kwargs
Initialize self See helptypeself for accurate signature
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted

Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
sklearnbase ClusterMixin
classsklearnbase ClusterMixin
Mixin class for all cluster estimators in scikitlearn
Methods
fitpredict self X y Performs clustering on X and returns cluster labels
init selfargs kwargs
Initialize self See helptypeself for accurate signature
fitpredict selfXyNone
Performs clustering on X and returns cluster labels
Parameters
Xndarray shape nsamples nfeatures Input data
yIgnored not used present for API consistency by convention
Returns
labels ndarray shape nsamples cluster labels
sklearnbase DensityMixin
classsklearnbase DensityMixin
Mixin class for all density estimators in scikitlearn
Methods
score self X y Returns the score of the model on the data X
init selfargs kwargs
Initialize self See helptypeself for accurate signature
scoreselfXyNone
Returns the score of the model on the data X
Parameters
Xarraylike shape nsamples nfeatures

Returns
score float
sklearnbase RegressorMixin
classsklearnbase RegressorMixin
Mixin class for all regression estimators in scikitlearn
Methods
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
init selfargs kwargs
Initialize self See helptypeself for accurate signature
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
sklearnbase TransformerMixin
classsklearnbase TransformerMixin
Mixin class for all transformers in scikitlearn

Methods
fittransform self X y Fit to data then transform it
init selfargs kwargs
Initialize self See helptypeself for accurate signature
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
Examples using sklearnbaseTransformerMixin
•Column Transformer with Heterogeneous Data Sources

showversions Print useful debugging information
sklearnbase clone
sklearnbase cloneestimator safeTrue
Constructs a new estimator with the same parameters
Clone does a deep copy of the model in an estimator without actually copying attached data It yields a new
estimator with the same parameters that has not been fit on any data
Parameters
estimator estimator object or list tuple or set of objects The estimator or group of estimators
to be cloned
safe boolean optional If safe is false clone will fall back to a deep copy on objects that are
not estimators

sklearnbase isclassifier
sklearnbase isclassifier estimator
Returns True if the given estimator is probably a classifier
Parameters
estimator object Estimator object to test
Returns
out bool True if estimator is a classifier and False otherwise
sklearnbase isregressor
sklearnbase isregressor estimator
Returns True if the given estimator is probably a regressor
Parameters
estimator object Estimator object to test
Returns
out bool True if estimator is a regressor and False otherwise
sklearn configcontext
sklearn configcontext newconfig
Context manager for global scikitlearn configuration
Parameters
assumefinite bool optional If True validation for finiteness will be skipped saving time but
leading to potential crashes If False validation for finiteness will be performed avoiding
error Global default False
workingmemory int optional If set scikitlearn will attempt to limit the size of temporary
arrays to this number of MiB per job when parallelised often saving both computation
time and memory on expensive operations that can be performed in chunks Global default
1024
See also
setconfig Set global scikitlearn configuration
getconfig Retrieve current values of the global configuration
Notes
All settings not just those presently modified will be returned to their previous values when the context manager
is exited This is not threadsafe
Examples

```
 import sklearn
 from sklearnutilsvalidation import assertallfinite
 with sklearnconfigcontextassumefinite True
 assertallfinitefloatnan
 with sklearnconfigcontextassumefinite True
 with sklearnconfigcontextassumefinite False
 assertallfinitefloatnan

Traceback most recent call last

ValueError Input contains NaN
```

sklearn getconfig

sklearn getconfig

Retrieve current values for configuration set by setconfig

Returns

config dict Keys are parameter names that can be passed to setconfig

See also

configcontext Context manager for global scikitlearn configuration

setconfig Set global scikitlearn configuration

sklearn setconfig

sklearn setconfig assumefiniteNone workingmemoryNone printchangedonlyNone

Set global scikitlearn configuration

New in version 019

Parameters

assumefinite bool optional If True validation for finiteness will be skipped saving time but leading to potential crashes If False validation for finiteness will be performed avoiding error Global default False

New in version 019

workingmemory int optional If set scikitlearn will attempt to limit the size of temporary arrays to this number of MiB per job when parallelised often saving both computation time and memory on expensive operations that can be performed in chunks Global default 1024

New in version 020

printchangedonly bool optional If True only the parameters that were set to nondefault values will be printed when printing an estimator For example printSVC while True will only print ‘SVC’ while the default behaviour would be to print ‘SVCC10 cachesize200 ’ with all the nonchanged parameters

New in version 021

62sklearncalibration Probability Calibration
Calibration of predicted probabilities
User guide See the Probability calibration section for further details
calibrationCalibratedClassifierCV Probability calibration with isotonic regression or sigmoid
621sklearncalibration CalibratedClassifierCV
classsklearncalibration CalibratedClassifierCV baseestimatorNone
method’sigmoid’ cv’warn’
Probability calibration with isotonic regression or sigmoid
See glossary entry for crossvalidation estimator
With this class the baseestimator is fit on the train set of the crossvalidation generator and the test set is used for calibration The probabilities for each of the folds are then averaged for prediction In case that cv”prefit” is passed to init it is assumed that baseestimator has been fitted already and all data is used for calibration Note that data for fitting the classifier and for calibrating it must be disjoint
Read more in the User Guide
Parameters
baseestimator instance BaseEstimator The classifier whose output decision function needs to be calibrated to offer more accurate predictproba outputs If cvprefit the classifier must have been fit already on data
method ‘sigmoid’ or ‘isotonic’ The method to use for calibration Can be ‘sigmoid’ which corresponds to Platt’s method or ‘isotonic’ which is a nonparametric approach It is not advised to use isotonic calibration with too few calibration samples 1000 since it tends to overfit Use sigmoids Platt’s calibration in this case
cvinteger crossvalidation generator iterable or “prefit” optional Determines the cross validation splitting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices

For integerNone inputs if yis binary or multiclass sklearnmodelselection
StratifiedKFold is used If yis neither binary nor multiclass sklearn
modelselectionKFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
If “prefit” is passed it is assumed that baseestimator has been fitted already and all data is
used for calibration
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
Attributes
classes array shape nclasses The class labels
calibratedclassifiers list len equal to cv or 1 if cv “prefit” The list of calibrated
classifiers one for each crossvalidation fold which has been fitted on all but the validation
fold and calibrated on the validation fold

•Probability calibration of classifiers
•Probability Calibration for 3class classification

calibrationcalibrationcurve ytrue
yprobCompute true and predicted probabilities for a calibration
curve
622sklearncalibration calibrationcurve
sklearncalibration calibrationcurve ytrue yprob normalizeFalse nbins5 strat
egy’uniform’
Compute true and predicted probabilities for a calibration curve
The method assumes the inputs come from a binary classifier
Calibration curves may also be referred to as reliability diagrams
Read more in the User Guide
Parameters
ytrue array shape nsamples True targets
yprob array shape nsamples Probabilities of the positive class
normalize bool optional defaultFalse Whether yprob needs to be normalized into the bin
0 1 ie is not a proper probability If True the smallest value in yprob is mapped onto
0 and the largest one onto 1
nbins int Number of bins A bigger number requires more data Bins with no data points
ie without corresponding values in yprob will not be returned thus there may be fewer
than nbins in the return value
strategy ‘uniform’ ‘quantile’ default’uniform’ Strategy used to define the widths of the
bins
uniform All bins have identical widths
quantile All bins have the same number of points
Returns
probtrue array shape nbins or smaller The true probability in each bin fraction of posi
tives
probpred array shape nbins or smaller The mean predicted probability in each bin

clusterKMeans nclusters init ninit KMeans clustering
clusterMiniBatchKMeans nclusters init MiniBatch KMeans clustering
clusterMeanShift bandwidth seeds Mean shift clustering using a flat kernel
clusterSpectralClustering nclusters Apply clustering to a projection of the normalized Laplacian
sklearncluster AffinityPropagation
classsklearncluster AffinityPropagation damping05 maxiter200 convergenceiter15 copyTrue preferenceNone affinity’euclidean’ verboseFalse
Perform Affinity Propagation Clustering of data
Read more in the User Guide
Parameters
damping float optional default 05 Damping factor between 05 and 1 is the extent to which the current value is maintained relative to incoming values weighted 1 damping This in order to avoid numerical oscillations when updating these values messages
maxiter int optional default 200 Maximum number of iterations
convergenceiter int optional default 15 Number of iterations with no change in the number of estimated clusters that stops the convergence
copy boolean optional default True Make a copy of input data
preference arraylike shape nsamples or float optional Preferences for each point points with larger values of preferences are more likely to be chosen as exemplars The number of exemplars ie of clusters is influenced by the input preferences value If the preferences are not passed as arguments they will be set to the median of the input similarities
affinity string optional default‘‘euclidean‘‘ Which affinity to use At the moment precomputed andeuclidean are supported euclidean uses the negative squared euclidean distance between points
verbose boolean optional default False Whether to be verbose
Attributes

clustercentersindices array shape nclusters Indices of cluster centers
clustercenters array shape nclusters nfeatures Cluster centers if affinity
precomputed
labels array shape nsamples Labels of each point
affinitymatrix array shape nsamples nsamples Stores the affinity matrix used in fit
niter int Number of iterations taken to converge
Notes
For an example see examplesclusterplotaffinitypropagationpy
The algorithmic complexity of affinity propagation is quadratic in the number of points
Whenfit does not converge clustercenters becomes an empty array and all training samples will be
labelled as1 In addition predict will then label every sample as 1
When all training samples have equal similarities and equal preferences the assignment of cluster centers and
labels depends on the preference If the preference is smaller than the similarities fit will result in a single
cluster center and label 0for every sample Otherwise every training sample becomes its own cluster center
and is assigned a unique label

oryNone connectivityNone com
putefulltree’auto’ linkage’ward’
poolingfunc’deprecated’ dis
tancethresholdNone
Agglomerative Clustering
Recursively merges the pair of clusters that minimally increases a given linkage distance
Read more in the User Guide
Parameters
nclusters int or None optional default2 The number of clusters to find It must be None
ifdistancethreshold is notNone
affinity string or callable default “euclidean” Metric used to compute the linkage Can be
“euclidean” “l1” “l2” “manhattan” “cosine” or “precomputed” If linkage is “ward”
only “euclidean” is accepted If “precomputed” a distance matrix instead of a similarity
matrix is needed as input for the fit method
memory None str or object with the joblibMemory interface optional Used to cache the
output of the computation of the tree By default no caching is done If a string is given it
is the path to the caching directory
connectivity arraylike or callable optional Connectivity matrix Defines for each sample the
neighboring samples following a given structure of the data This can be a connectivity
matrix itself or a callable that transforms the data into a connectivity matrix such as de
rived from kneighborsgraph Default is None ie the hierarchical clustering algorithm is
unstructured
computefulltree bool or ‘auto’ optional Stop early the construction of the tree at
nclusters This is useful to decrease computation time if the number of clusters is not small
compared to the number of samples This option is useful only when specifying a connec
tivity matrix Note also that when varying the number of clusters and using caching it may
be advantageous to compute the full tree It must be True ifdistancethreshold is
notNone
linkage “ward” “complete” “average” “single” optional default”ward” Which linkage
criterion to use The linkage criterion determines which distance to use between sets of
observation The algorithm will merge the pairs of cluster that minimize this criterion
• ward minimizes the variance of the clusters being merged
• average uses the average of the distances of each observation of the two sets
• complete or maximum linkage uses the maximum distances between all observations of
the two sets
• single uses the minimum of the distances between all observations of the two sets

poolingfunc callable default’deprecated’ Ignored
Deprecated since version 020 poolingfunc has been deprecated in 020 and will be
removed in 022
distancethreshold float optional defaultNone The linkage distance threshold above
which clusters will not be merged If not None nclusters must beNone and
computefulltree must beTrue
New in version 021
Attributes
nclusters int The number of clusters found by the algorithm If
distancethresholdNone it will be equal to the given nclusters
labels array nsamples cluster labels for each point
nleaves int Number of leaves in the hierarchical tree
nconnectedcomponents int The estimated number of connected components in the graph
children arraylike shape nsamples1 2 The children of each nonleaf node Values less
than nsamples correspond to leaves of the tree which are the original samples A node
igreater than or equal to nsamples is a nonleaf node and has children childreni
nsamples Alternatively at the ith iteration childreni0 and childreni1 are
merged to form node nsamples i

sklearncluster Birch
classsklearncluster Birchthreshold05 branchingfactor50 nclusters3 com
putelabelsTrue copyTrue
Implements the Birch clustering algorithm
It is a memoryefficient onlinelearning algorithm provided as an alternative to MiniBatchKMeans It con
structs a tree data structure with the cluster centroids being read off the leaf These can be either the final cluster
centroids or can be provided as input to another clustering algorithm such as AgglomerativeClustering
Read more in the User Guide
Parameters
threshold float default 05 The radius of the subcluster obtained by merging a new sample
and the closest subcluster should be lesser than the threshold Otherwise a new subcluster is
started Setting this value to be very low promotes splitting and viceversa
branchingfactor int default 50 Maximum number of CF subclusters in each node If a new
samples enters such that the number of subclusters exceed the branchingfactor then that
node is split into two nodes with the subclusters redistributed in each The parent subcluster
of that node is removed and two new subclusters are added as parents of the 2 split nodes
nclusters int instance of sklearncluster model default 3 Number of clusters after the final
clustering step which treats the subclusters from the leaves as new samples
•None the final clustering step is not performed and the subclusters are returned as they
are
•sklearncluster Estimator If a model is provided the model is fit treating the
subclusters as new samples and the initial data is mapped to the label of the closest sub
cluster
•int the model fit is AgglomerativeClustering withnclusters set to be
equal to the int
computelabels bool default True Whether or not to compute labels for each fit
copy bool default True Whether or not to make a copy of the given data If set to False the
initial data will be overwritten
Attributes
root CFNode Root of the CFTree
dummyleaf CFNode Start pointer to all the leaves
subclustercenters ndarray Centroids of all subclusters read directly from the leaves
subclusterlabels ndarray Labels assigned to the centroids of the subclusters after they are
clustered globally
labels ndarray shape nsamples Array of labels assigned to the input data if partialfit is
used instead of fit they are assigned to the last batch of data
Notes
The tree data structure consists of nodes with each node consisting of a number of subclusters The maximum
number of subclusters in a node is determined by the branching factor Each subcluster maintains a linear sum
squared sum and the number of samples in that subcluster In addition each subcluster can also have a node as
its child if the subcluster is not a member of a leaf node

For a new point entering the root it is merged with the subcluster closest to it and the linear sum squared sum and the number of samples of that subcluster are updated This is done recursively till the properties of the leaf node are updated

fitpredict self X y Performs clustering on X and returns cluster labels
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
partialfit self X y Online learning
predict self X Predict data using the centroids of subclusters
setparams self params Set the parameters of this estimator
transform self X Transform X into subcluster centroids dimension

```
init selfthreshold05 branchingfactor50 nclusters3 computelabelsTrue
copyTrue
```

fitselfXyNone

Build a CF Tree for the input data

Parameters

Xarraylike sparse matrix shape nsamples nfeatures Input data
yIgnored

fitpredict selfXyNone

Performs clustering on X and returns cluster labels

Parameters

Xndarray shape nsamples nfeatures Input data

yIgnored not used present for API consistency by convention
Returns
labels ndarray shape nsamples cluster labels
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXNone yNone
Online learning Prevents rebuilding of CFTree from scratch
Parameters
Xarraylike sparse matrix shape nsamples nfeatures None Input data If X is not
provided only the global clustering step is done
yIgnored
predictselfX
Predict data using the centroids of subclusters
Avoid computation of the row norms of X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Input data
Returns
labels ndarray shapensamples Labelled data
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfX
Transform X into subcluster centroids dimension
Each dimension represents the distance from the sample point to each cluster centroid
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Input data
Returns
Xtrans arraylike sparse matrix shape nsamples nclusters Transformed data
Examples using sklearnclusterBirch
•Compare BIRCH and MiniBatchKMeans
•Comparing different clustering algorithms on toy datasets
sklearncluster DBSCAN
classsklearncluster DBSCANeps05 minsamples5 metric'euclidean' metricparamsNone
algorithm'auto' leafsize30 pNone njobsNone
Perform DBSCAN clustering from vector array or distance matrix
DBSCAN DensityBased Spatial Clustering of Applications with Noise Finds core samples of high density
and expands clusters from them Good for data which contains clusters of similar density
Read more in the User Guide
Parameters
eps float optional The maximum distance between two samples for one to be considered as
in the neighborhood of the other This is not a maximum bound on the distances of points
within a cluster This is the most important DBSCAN parameter to choose appropriately for
your data set and distance function
minsamples int optional The number of samples or total weight in a neighborhood for a
point to be considered as a core point This includes the point itself
metric string or callable The metric to use when calculating distance between instances in
a feature array If metric is a string or callable it must be one of the options allowed
bysklearnmetricspairwisedistances for its metric parameter If metric
is "precomputed" X is assumed to be a distance matrix and must be square X may be
a sparse matrix in which case only "nonzero" elements may be considered neighbors for
DBSCAN
New in version 017 metric precomputed to accept precomputed sparse matrix
metricparams dict optional Additional keyword arguments for the metric function
New in version 019
algorithm 'auto' 'balltree' 'kdtree' 'brute' optional The algorithm to be used by the
NearestNeighbors module to compute pointwise distances and find nearest neighbors See
NearestNeighbors module documentation for details
leafsize int optional default 30 Leaf size passed to BallTree or cKDTree This can affect
the speed of the construction and query as well as the memory required to store the tree
The optimal value depends on the nature of the problem

pfloat optional The power of the Minkowski metric to be used to calculate distance between points
njobs int or None optional defaultNone The number of parallel jobs to run None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
Attributes
coresampleindices array shape ncoresamples Indices of core samples
components array shape ncoresamples nfeatures Copy of each core sample found by training
labels array shape nsamples Cluster labels for each point in the dataset given to fit Noisy samples are given the label 1
See also
OPTICS A similar clustering at multiple values of eps Our implementation is optimized for memory usage
Notes
For an example see examplesclusterplotdbscanpy
This implementation bulkcomputes all neighborhood queries which increases the memory complexity to Ond where d is the average number of neighbors while original DBSCAN had memory complexity On It may attract a higher memory complexity when querying these nearest neighborhoods depending on the algorithm
One way to avoid the query complexity is to precompute sparse neighborhoods in chunks usingNearestNeighborsradiusneighborsgraph withmodedistance then using metricprecomputed here
Another way to reduce memory and computation time is to remove nearduplicate points and use sampleweight instead
clusterOPTICS provides a similar clustering with lower memory usage

Examples using sklearnclusterDBSCAN
•Demo of DBSCAN clustering algorithm
•Comparing different clustering algorithms on toy datasets
sklearncluster OPTICS
classsklearncluster OPTICSminsamples5 maxepsinf metric’minkowski’ p2met
ricparamsNone clustermethod’xi’ epsNone xi005 prede
cessorcorrectionTrue minclustersizeNone algorithm’auto’
leafsize30 njobsNone
Estimate clustering structure from vector array
OPTICS Ordering Points To Identify the Clustering Structure closely related to DBSCAN finds core sample
of high density and expands clusters from them R2c55e37003fe1 Unlike DBSCAN keeps cluster hierarchy
for a variable neighborhood radius Better suited for usage on large datasets than the current sklearn implemen
tation of DBSCAN
Clusters are then extracted using a DBSCANlike method clustermethod ‘dbscan’ or an automatic technique
proposed in R2c55e37003fe1 clustermethod ‘xi’
This implementation deviates from the original OPTICS by first performing knearestneighborhood searches
on all points to identify core sizes then computing only the distances to unprocessed points when constructing
the cluster order Note that we do not employ a heap to manage the expansion candidates so the time complexity
will be On2
Read more in the User Guide
Parameters
minsamples int 1 or float between 0 and 1 default5 The number of samples in a neigh
borhood for a point to be considered as a core point Also up and down steep regions can’t
have more then minsamples consecutive nonsteep points Expressed as an absolute
number or a fraction of the number of samples rounded to be at least 2
maxeps float optional defaultnpinf The maximum distance between two samples for one
to be considered as in the neighborhood of the other Default value of npinf will identify
clusters across all scales reducing maxeps will result in shorter run times
metric string or callable optional default’minkowski’ Metric to use for distance computa
tion Any metric from scikitlearn or scipyspatialdistance can be used
If metric is a callable function it is called on each pair of instances rows and the resulting
value recorded The callable should take two arrays as input and return one value indicating

the distance between them This works for Scipy’s metrics but is less efficient than passing the metric name as a string If metric is “precomputed” X is assumed to be a distance matrix and must be square
Valid values for metric are
• from scikitlearn ‘cityblock’ ‘cosine’ ‘euclidean’ ‘l1’ ‘l2’ ‘manhattan’
• from scipyspatialdistance ‘braycurtis’ ‘canberra’ ‘chebyshev’ ‘correlation’ ‘dice’ ‘hamming’ ‘jaccard’ ‘kulsinski’ ‘mahalanobis’ ‘minkowski’ ‘rogerstanimoto’ ‘rus sellrao’ ‘seuclidean’ ‘sokalmichener’ ‘sokalsneath’ ‘sqeuclidean’ ‘yule’
See the documentation for scipyspatialdistance for details on these metrics
pinteger optional default2 Parameter for the Minkowski metric from sklearn metricspairwisedistances When p 1 this is equivalent to using manhat tandistance l1 and euclideandistance l2 for p 2 For arbitrary p minkowskidistance lp is used
metricparams dict optional defaultNone Additional keyword arguments for the metric function
clustermethod string optional default’xi’ The extraction method used to extract clusters using the calculated reachability and ordering Possible values are “xi” and “dbscan”
eps float optional defaultNone The maximum distance between two samples for one to be considered as in the neighborhood of the other By default it assumes the same value as maxeps Used only when clustermethoddbscan
xifloat between 0 and 1 optional default005 Determines the minimum steepness on the reachability plot that constitutes a cluster boundary For example an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1xi Used only when clustermethodxi
predecessorcorrection bool optional defaultTrue Correct clusters according to the pre decessors calculated by OPTICS R2c55e37003fe2 This parameter has minimal effect on most datasets Used only when clustermethodxi
minclustersize int 1 or float between 0 and 1 defaultNone Minimum number of sam ples in an OPTICS cluster expressed as an absolute number or a fraction of the number of samples rounded to be at least 2 If None the value of minsamples is used instead Used only when clustermethodxi
algorithm ‘auto’ ‘balltree’ ‘kdtree’ ‘brute’ optional Algorithm used to compute the nearest neighbors
• ‘balltree’ will use BallTree
• ‘kdtree’ will use KDTree
• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed tofit method default
Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default30 Leaf size passed to BallTree orKDTree This can affect the speed of the construction and query as well as the memory required to store the tree The optimal value depends on the nature of the problem

njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details
Attributes

yIgnored
Returns
self
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set

ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfXred
Inverse the transformation Return a vector of size nbfeatures with the values of Xred assigned to each
group of features
Parameters
Xred arraylike shapensamples nclusters or nclusters The values to be assigned
to each cluster of samples
Returns
Xarray shapensamples nfeatures or nfeatures A vector of size nsamples with
the values of Xred assigned to each of the cluster of samples
poolingfunc aaxisNone dtypeNone outNone keepdimsno value
Compute the arithmetic mean along the specified axis
Returns the average of the array elements The average is taken over the flattened array by default other
wise over the specified axis float64 intermediate and return values are used for integer inputs
Parameters
aarraylike Array containing numbers whose mean is desired If ais not an array a
conversion is attempted
axis None or int or tuple of ints optional Axis or axes along which the means are com
puted The default is to compute the mean of the flattened array
New in version 170
If this is a tuple of ints a mean is performed over multiple axes instead of a single axis or
all the axes as before
dtype datatype optional Type to use in computing the mean For integer inputs the
default isfloat64 for floating point inputs it is the same as the input dtype
out ndarray optional Alternate output array in which to place the result The default is
None if provided it must have the same shape as the expected output but the type will
be cast if necessary See docufuncs for details
keepdims bool optional If this is set to True the axes which are reduced are left in the
result as dimensions with size one With this option the result will broadcast correctly
against the input array
If the default value is passed then keepdims will not be passed through to the mean
method of subclasses of ndarray however any nondefault value will be If the sub
class’ method does not implement keepdims any exceptions will be raised

Returns
mndarray see dtype parameter above If outNone returns a new array containing the
mean values otherwise a reference to the output array is returned
See also
average Weighted average
stdvarnanmean nanstd nanvar
Notes
The arithmetic mean is the sum of the elements along the axis divided by the number of elements
Note that for floatingpoint input the mean is computed using the same precision the input has Depending
on the input data this can cause the results to be inaccurate especially for float32 see example below
Specifying a higherprecision accumulator using the dtype keyword can alleviate this issue
By default float16 results are computed using float32 intermediates for extra precision
Examples

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform a new matrix using the built clustering

Parameters
Xarraylike shape nsamples nfeatures or nfeatures A M by N array of M obser
vations in N dimensions or a length M array of M onedimensional observations
Returns
Yarray shape nsamples nclusters or nclusters The pooled values for each feature
cluster
Examples using sklearnclusterFeatureAgglomeration
•Feature agglomeration
•Feature agglomeration vs univariate selection
sklearncluster KMeans
classsklearncluster KMeansnclusters8 init'kmeans' ninit10 maxiter300
tol00001 precomputedistances'auto' verbose0 ran
domstateNone copyxTrue njobsNone algorithm'auto'
KMeans clustering
Read more in the User Guide
Parameters
nclusters int optional default 8 The number of clusters to form as well as the number of
centroids to generate
init 'kmeans' 'random' or an ndarray Method for initialization defaults to 'k
means'
'kmeans' selects initial cluster centers for kmean clustering in a smart way to speed
up convergence See section Notes in kinit for more details
'random' choose k observations rows at random from data for the initial centroids
If an ndarray is passed it should be of shape nclusters nfeatures and gives the initial
centers
ninit int default 10 Number of time the kmeans algorithm will be run with different cen
troid seeds The final results will be the best output of ninit consecutive runs in terms of
inertia
maxiter int default 300 Maximum number of iterations of the kmeans algorithm for a
single run
tolfloat default 1e4 Relative tolerance with regards to inertia to declare convergence
precomputedistances 'auto' True False Precompute distances faster but takes more
memory
'auto' do not precompute distances if nsamples nclusters 12 million This corre
sponds to about 100MB overhead per job using double precision
True always precompute distances
False never precompute distances
verbose int default 0 Verbosity mode

randomstate int RandomState instance or None default Determines random number gen
eration for centroid initialization Use an int to make the randomness deterministic See
Glossary
copyx boolean optional When precomputing distances it is more numerically accurate to
center the data first If copyx is True default then the original data is not modified
ensuring X is Ccontiguous If False the original data is modified and put back before the
function returns but small numerical differences may be introduced by subtracting and then
adding the data mean in this case it will also not ensure that data is Ccontiguous which
may cause a significant slowdown
njobs int or None optional defaultNone The number of jobs to use for the computation
This works by computing each of the ninit runs in parallel
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
algorithm “auto” “full” or “elkan” default”auto” Kmeans algorithm to use The classical
EMstyle algorithm is “full” The “elkan” variation is more efficient by using the triangle
inequality but currently doesn’t support sparse data “auto” chooses “elkan” for dense data
and “full” for sparse data
Attributes
clustercenters array nclusters nfeatures Coordinates of cluster centers If the algo
rithm stops before fully converging see tol andmaxiter these will not be consistent
withlabels
labels Labels of each point
inertia float Sum of squared distances of samples to their closest cluster center
niter int Number of iterations run
See also
MiniBatchKMeans Alternative online implementation that does incremental updates of the centers positions
using minibatches For large scale learning say nsamples 10k MiniBatchKMeans is probably much
faster than the default batch implementation
Notes
The kmeans problem is solved using either Lloyd’s or Elkan’s algorithm
The average complexity is given by Ok n T were n is the number of samples and T is the number of iteration
The worst case complexity is given by Onk2p with n nsamples p nfeatures D Arthur and S
Vassilvitskii ‘How slow is the kmeans method’ SoCG2006
In practice the kmeans algorithm is very fast one of the fastest clustering algorithms available but it falls in
local minima That’s why it can be useful to restart it several times
If the algorithm stops before fully converging because of tol ormaxiter labels and
clustercenters will not be consistent ie the clustercenters will not be the means of the
points in each cluster Also the estimator will reassign labels after the last iteration to make labels
consistent with predict on the training set

Examples
```
 from sklearncluster import KMeans
 import numpy as np

Methods
fitself X y sampleweight Compute kmeans clustering
fitpredict self X y sampleweight Compute cluster centers and predict cluster index for each sample
fittransform self X y sampleweight Compute clustering and transform X to clusterdistance space
getparams self deep Get parameters for this estimator
predict self X sampleweight Predict the closest cluster each sample in X belongs to
score self X y sampleweight Opposite of the value of X on the Kmeans objective
setparams self params Set the parameters of this estimator
transform self X Transform X to a clusterdistance space
init selfnclusters8 init'kmeans' ninit10 maxiter300 tol00001 precom putedistances'auto' verbose0 randomstateNone copyxTrue njobsNone algorithm'auto'
fitselfXyNone sampleweightNone
Compute kmeans clustering
Parameters
Xarraylike or sparse matrix shapensamples nfeatures Training instances to cluster
It must be noted that the data will be converted to C ordering which will cause a memory copy if the given data is not Ccontiguous
yIgnored not used present here for API consistency by convention
sampleweight arraylike shape nsamples optional The weights for each observation in X If None all observations are assigned equal weight default None
fitpredict selfXyNone sampleweightNone
Compute cluster centers and predict cluster index for each sample
Convenience method equivalent to calling fitX followed by predictX
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to transform
yIgnored not used present here for API consistency by convention

sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns
labels array shape nsamples Index of the cluster each sample belongs to
fittransform selfXyNone sampleweightNone
Compute clustering and transform X to clusterdistance space
Equivalent to fitXtransformX but more efficiently implemented
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to transform
yIgnored not used present here for API consistency by convention
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns
Xnew array shape nsamples k X transformed in the new space
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfXsampleweightNone
Predict the closest cluster each sample in X belongs to
In the vector quantization literature clustercenters is called the code book and each value re
turned bypredict is the index of the closest code in the code book
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to predict
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns
labels array shape nsamples Index of the cluster each sample belongs to
scoreselfXyNone sampleweightNone
Opposite of the value of X on the Kmeans objective
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data
yIgnored not used present here for API consistency by convention
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns

score float Opposite of the value of X on the Kmeans objective
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform X to a clusterdistance space
In the new space each dimension is the distance to the cluster centers Note that even if X is sparse the
array returned by transform will typically be dense
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to transform
Returns
Xnew array shape nsamples k X transformed in the new space
Examples using sklearnclusterKMeans
•Demonstration of kmeans assumptions
•Vector Quantization Example

sklearncluster MiniBatchKMeans
classsklearncluster MiniBatchKMeans nclusters8 init’kmeans’ maxiter100
batchsize100 verbose0 computelabelsTrue
randomstateNone tol00 maxnoimprovement10
initsizeNone ninit3 reassignmentratio001
MiniBatch KMeans clustering
Read more in the User Guide
Parameters
nclusters int optional default 8 The number of clusters to form as well as the number of
centroids to generate

init ‘kmeans’ ‘random’ or an ndarray default ‘kmeans’ Method for initialization
defaults to ‘kmeans’
‘kmeans’ selects initial cluster centers for kmean clustering in a smart way to speed
up convergence See section Notes in kinit for more details
‘random’ choose k observations rows at random from data for the initial centroids
If an ndarray is passed it should be of shape nclusters nfeatures and gives the initial
centers
maxiter int optional Maximum number of iterations over the complete dataset before stop
ping independently of any early stopping criterion heuristics
batchsize int optional default 100 Size of the mini batches
verbose boolean optional Verbosity mode
computelabels boolean defaultTrue Compute label assignment and inertia for the com
plete dataset once the minibatch optimization has converged in fit
randomstate int RandomState instance or None default Determines random number gen
eration for centroid initialization and random reassignment Use an int to make the random
ness deterministic See Glossary
tolfloat default 00 Control early stopping based on the relative center changes as measured
by a smoothed variancenormalized of the mean center squared position changes This
early stopping heuristics is closer to the one used for the batch variant of the algorithms but
induces a slight computational and memory overhead over the inertia heuristic
To disable convergence detection based on normalized center change set tol to 00 default
maxnoimprovement int default 10 Control early stopping based on the consecutive num
ber of mini batches that does not yield an improvement on the smoothed inertia
To disable convergence detection based on inertia set maxnoimprovement to None
initsize int optional default 3 batchsize Number of samples to randomly sample for
speeding up the initialization sometimes at the expense of accuracy the only algorithm
is initialized by running a batch KMeans on a random subset of the data This needs to be
larger than nclusters
ninit int default3 Number of random initializations that are tried In contrast to KMeans
the algorithm is only run once using the best of the ninit initializations as measured by
inertia
reassignmentratio float default 001 Control the fraction of the maximum number of
counts for a center to be reassigned A higher value means that low count centers are more
easily reassigned which means that the model will take longer to converge but should con
verge in a better clustering
Attributes
clustercenters array nclusters nfeatures Coordinates of cluster centers
labels Labels of each point if computelabels is set to True
inertia float The value of the inertia criterion associated with the chosen partition if com
putelabels is set to True The inertia is defined as the sum of square distances of samples
to their nearest neighbor

in X If None all observations are assigned equal weight default None
Returns
Xnew array shape nsamples k X transformed in the new space
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyNone sampleweightNone
Update k means estimate on a single minibatch X

Parameters
Xarraylike shape nsamples nfeatures Coordinates of the data points to cluster It
must be noted that X will be copied if it is not Ccontiguous
yIgnored not used present here for API consistency by convention
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
predictselfXsampleweightNone
Predict the closest cluster each sample in X belongs to
In the vector quantization literature clustercenters is called the code book and each value re
turned bypredict is the index of the closest code in the code book
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to predict
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns
labels array shape nsamples Index of the cluster each sample belongs to
scoreselfXyNone sampleweightNone
Opposite of the value of X on the Kmeans objective
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data
yIgnored not used present here for API consistency by convention
sampleweight arraylike shape nsamples optional The weights for each observation
in X If None all observations are assigned equal weight default None
Returns
score float Opposite of the value of X on the Kmeans objective
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform X to a clusterdistance space
In the new space each dimension is the distance to the cluster centers Note that even if X is sparse the
array returned by transform will typically be dense
Parameters
Xarraylike sparse matrix shape nsamples nfeatures New data to transform
Returns
Xnew array shape nsamples k X transformed in the new space

Examples using sklearnclusterMiniBatchKMeans
•Biclustering documents with the Spectral Coclustering algorithm
•Online learning of a dictionary of parts of faces
•Compare BIRCH and MiniBatchKMeans
•Empirical evaluation of the impact of kmeans initialization
•Comparison of the KMeans and MiniBatchKMeans clustering algorithms
•Comparing different clustering algorithms on toy datasets
•Faces dataset decompositions
•Clustering text documents using kmeans
sklearncluster MeanShift
classsklearncluster MeanShift bandwidthNone seedsNone binseedingFalse
minbinfreq1 clusterallTrue njobsNone
Mean shift clustering using a flat kernel
Mean shift clustering aims to discover “blobs” in a smooth density of samples It is a centroidbased algo
rithm which works by updating candidates for centroids to be the mean of the points within a given region
These candidates are then filtered in a postprocessing stage to eliminate nearduplicates to form the final set of
centroids
Seeding is performed using a binning technique for scalability
Read more in the User Guide
Parameters
bandwidth float optional Bandwidth used in the RBF kernel
If not given the bandwidth is estimated using sklearnclusterestimatebandwidth see the
documentation for that function for hints on scalability see also the Notes below
seeds array shapensamples nfeatures optional Seeds used to initialize kernels If not
set the seeds are calculated by clusteringgetbinseeds with bandwidth as the grid size and
default values for other parameters
binseeding boolean optional If true initial kernel locations are not locations of all points
but rather the location of the discretized version of points where points are binned onto a
grid whose coarseness corresponds to the bandwidth Setting this option to True will speed
up the algorithm because fewer seeds will be initialized default value False Ignored if
seeds argument is not None
minbinfreq int optional To speed up the algorithm accept only those bins with at least
minbinfreq points as seeds If not defined set to 1
clusterall boolean default True If true then all points are clustered even those orphans that
are not within any kernel Orphans are assigned to the nearest kernel If false then orphans
are given cluster label 1
njobs int or None optional defaultNone The number of jobs to use for the computation
This works by computing each of the ninit runs in parallel
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details

Attributes
clustercenters array nclusters nfeatures Coordinates of cluster centers
labels Labels of each point
Notes
Scalability
Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel the complexity will tend towards OTnlogn in lower dimensions with n the number of samples and T the number of points
In higher dimensions the complexity will tend towards OTn2
Scalability can be boosted by using fewer seeds for example by using a higher value of minbinfreq in the getbinseeds function
Note that the estimatebandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used

sklearncluster SpectralClustering
classsklearncluster SpectralClustering nclusters8 eigensolverNone ran
domstateNone ninit10 gamma10 affin
ity'rbf' nneighbors10 eigentol00 as
signlabels'kmeans' degree3 coef01 ker
nelparamsNone njobsNone
Apply clustering to a projection of the normalized Laplacian
In practice Spectral Clustering is very useful when the structure of the individual clusters is highly nonconvex
or more generally when a measure of the center and spread of the cluster is not a suitable description of the
complete cluster For instance when clusters are nested circles on the 2D plane
If affinity is the adjacency matrix of a graph this method can be used to find normalized graph cuts
When calling fit an affinity matrix is constructed using either kernel function such the Gaussian aka RBF
kernel of the euclidean distanced dX X
npexpgamma dXX2
or a knearest neighbors connectivity matrix
Alternatively using precomputed a userprovided affinity matrix can be used
Read more in the User Guide
Parameters
nclusters integer optional The dimension of the projection subspace
eigensolver None 'arpack' 'lobpcg' or 'amg' The eigenvalue decomposition strategy to
use AMG requires pyamg to be installed It can be faster on very large sparse problems
but may also lead to instabilities
randomstate int RandomState instance or None default A pseudo random number
generator used for the initialization of the lobpcg eigen vectors decomposition when
eigensolveramg and by the KMeans initialization Use an int to make the ran
domness deterministic See Glossary
ninit int optional default 10 Number of time the kmeans algorithm will be run with dif
ferent centroid seeds The final results will be the best output of ninit consecutive runs in
terms of inertia
gamma float default10 Kernel coefficient for rbf poly sigmoid laplacian and chi2 kernels
Ignored for affinitynearestneighbors
affinity string arraylike or callable default 'rbf' If a string this may be one of 'near
estneighbors' 'precomputed' 'rbf' or one of the kernels supported by sklearn
metricspairwisekernels
Only kernels that produce similarity scores nonnegative values that increase with similar
ity should be used This property is not checked by the clustering algorithm
nneighbors integer Number of neighbors to use when constructing the affinity matrix using
the nearest neighbors method Ignored for affinityrbf
eigentol float optional default 00 Stopping criterion for eigendecomposition of the Lapla
cian matrix when eigensolverarpack
assignlabels 'kmeans' 'discretize' default 'kmeans' The strategy to use to assign labels
in the embedding space There are two ways to assign labels after the laplacian embedding

kmeans can be applied and is a popular choice But it can also be sensitive to initialization
Discretization is another approach which is less sensitive to random initialization
degree float default3 Degree of the polynomial kernel Ignored by other kernels
coef0 float default1 Zero coefficient for polynomial and sigmoid kernels Ignored by other
kernels
kernelparams dictionary of string to any optional Parameters keyword arguments and
values for kernel passed as callable object Ignored by other kernels
njobs int or None optional defaultNone The number of parallel jobs to run None means
1 unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
Attributes
affinitymatrix arraylike shape nsamples nsamples Affinity matrix used for cluster
ing Available only if after calling fit
labels Labels of each point
Notes
If you have an affinity matrix such as a distance matrix for which 0 means identical elements and high values
means very dissimilar elements it can be transformed in a similarity matrix that is well suited for the algorithm
by applying the Gaussian RBF heat kernel
npexp distmatrix 2 2 delta2
Wheredelta is a free parameter representing the width of the Gaussian kernel
Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points
If the pyamg package is installed it is used this greatly speeds up computation

sklearncluster affinitypropagation

sklearncluster affinitypropagation S preferenceNone convergenceiter15 maxiter200 damping05 copyTrue verboseFalse returnniterFalse

Perform Affinity Propagation Clustering of data

Read more in the User Guide

Parameters

Sarraylike shape nsamples nsamples Matrix of similarities between points

preference arraylike shape nsamples or float optional Preferences for each point points with larger values of preferences are more likely to be chosen as exemplars The number of exemplars ie of clusters is influenced by the input preferences value If the preferences are not passed as arguments they will be set to the median of the input similarities resulting in a moderate number of clusters For a smaller amount of clusters this can be set to the minimum value of the similarities

convergenceiter int optional default 15 Number of iterations with no change in the number of estimated clusters that stops the convergence

maxiter int optional default 200 Maximum number of iterations

damping float optional default 05 Damping factor between 05 and 1
copy boolean optional default True If copy is False the affinity matrix is modified inplace
by the algorithm for memory efficiency
verbose boolean optional default False The verbosity level
returnniter bool default False Whether or not to return the number of iterations
Returns
clustercentersindices array shape nclusters index of clusters centers
labels array shape nsamples cluster labels for each point
niter int number of iterations run Returned only if returnniter is set to True
Notes
For an example see examplesclusterplotaffinitypropagationpy
When the algorithm does not converge it returns an empty array as clustercenterindices and1as
label for each training sample
When all training samples have equal similarities and equal preferences the assignment of cluster centers and
labels depends on the preference If the preference is smaller than the similarities a single cluster center and
label0for every sample will be returned Otherwise every training sample becomes its own cluster center and
is assigned a unique label

reachability array shape nsamples Reachability distances calculated by OPTICS
reachability
predecessor array shape nsamples Predecessors calculated by OPTICS
ordering array shape nsamples OPTICS ordered point indices ordering
minsamples int 1 or float between 0 and 1 The same as the minsamples given to OPTICS
Up and down steep regions can’t have more then minsamples consecutive nonsteep
points Expressed as an absolute number or a fraction of the number of samples rounded to
be at least 2
minclustersize int 1 or float between 0 and 1 defaultNone Minimum number of sam
ples in an OPTICS cluster expressed as an absolute number or a fraction of the number of
samples rounded to be at least 2 If None the value of minsamples is used instead
xifloat between 0 and 1 optional default005 Determines the minimum steepness on the
reachability plot that constitutes a cluster boundary For example an upwards point in the
reachability plot is defined by the ratio from one point to its successor being at most 1xi
predecessorcorrection bool optional defaultTrue Correct clusters based on the calcu
lated predecessors
Returns
labels array shape nsamples The labels assigned to samples Points which are not included
in any cluster are labeled as 1
clusters array shape nclusters 2 The list of clusters in the form of start end
in each row with all indices inclusive The clusters are ordered according to end
start ascending so that larger clusters encompassing smaller clusters come af
ter such nested smaller clusters Since labels does not reflect the hierarchy usually
lenclusters npuniquelabels
sklearncluster computeopticsgraph
sklearncluster computeopticsgraph Xminsamples maxeps metric pmetricparams al
gorithm leafsize njobs
Computes the OPTICS reachability graph
Read more in the User Guide

Parameters
Xarray shape nsamples nfeatures or nsamples nsamples if metric’precomputed’
A feature array or array of distances between samples if metric’precomputed’
minsamples int 1 or float between 0 and 1 The number of samples in a neighborhood for a point to be considered as a core point Expressed as an absolute number or a fraction of the number of samples rounded to be at least 2
maxeps float optional defaultnpinf The maximum distance between two samples for one to be considered as in the neighborhood of the other Default value of npinf will identify clusters across all scales reducing maxeps will result in shorter run times
metric string or callable optional default’minkowski’ Metric to use for distance computa tion Any metric from scikitlearn or scipyspatialdistance can be used
If metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays as input and return one value indicating the distance between them This works for Scipy’s metrics but is less efficient than passing the metric name as a string If metric is “precomputed” X is assumed to be a distance matrix and must be square
Valid values for metric are
• from scikitlearn ‘cityblock’ ‘cosine’ ‘euclidean’ ‘l1’ ‘l2’ ‘manhattan’
• from scipyspatialdistance ‘braycurtis’ ‘canberra’ ‘chebyshev’ ‘correlation’ ‘dice’ ‘hamming’ ‘jaccard’ ‘kulsinski’ ‘mahalanobis’ ‘minkowski’ ‘rogerstanimoto’ ‘rus sellrao’ ‘seuclidean’ ‘sokalmichener’ ‘sokalsneath’ ‘sqeuclidean’ ‘yule’
See the documentation for scipyspatialdistance for details on these metrics
pinteger optional default2 Parameter for the Minkowski metric from sklearn metricspairwisedistances When p 1 this is equivalent to using manhat tandistance l1 and euclideandistance l2 for p 2 For arbitrary p minkowskidistance lp is used
metricparams dict optional defaultNone Additional keyword arguments for the metric function
algorithm ‘auto’ ‘balltree’ ‘kdtree’ ‘brute’ optional Algorithm used to compute the nearest neighbors
• ‘balltree’ will use BallTree
• ‘kdtree’ will use KDTree
• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed tofit method default
Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default30 Leaf size passed to BallTree orKDTree This can affect the speed of the construction and query as well as the memory required to store the tree The optimal value depends on the nature of the problem
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors searchNone means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
Returns

ordering array shape nsamples The cluster ordered list of sample indices
coredistances array shape nsamples Distance at which each sample becomes a core point indexed by object order Points which will never be core have a distance of inf Use clustcoredistancesclustordering to access in cluster order
reachability array shape nsamples Reachability distances per sample indexed by object order Useclustreachabilityclustordering to access in cluster order
predecessor array shape nsamples Point that a sample was reached from indexed by object order Seed points have a predecessor of 1
References
1
sklearncluster dbscan
sklearncluster dbscanXeps05 minsamples5 metric'minkowski' metricparamsNone algorithm'auto' leafsize30 p2sampleweightNone njobsNone
Perform DBSCAN clustering from vector array or distance matrix
Read more in the User Guide
Parameters
Xarray or sparse CSR matrix of shape nsamples nfeatures or array of shape nsamples nsamples A feature array or array of distances between samples if metricprecomputed
eps float optional The maximum distance between two samples for one to be considered as in the neighborhood of the other This is not a maximum bound on the distances of points within a cluster This is the most important DBSCAN parameter to choose appropriately for your data set and distance function
minsamples int optional The number of samples or total weight in a neighborhood for a point to be considered as a core point This includes the point itself
metric string or callable The metric to use when calculating distance between instances in a feature array If metric is a string or callable it must be one of the options allowed bysklearnmetricspairwisedistances for its metric parameter If metric is "precomputed" X is assumed to be a distance matrix and must be square X may be a sparse matrix in which case only "nonzero" elements may be considered neighbors for DBSCAN
metricparams dict optional Additional keyword arguments for the metric function New in version 019
algorithm 'auto' 'balltree' 'kdtree' 'brute' optional The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors See NearestNeighbors module documentation for details
leafsize int optional default 30 Leaf size passed to BallTree or cKDTree This can affect the speed of the construction and query as well as the memory required to store the tree The optimal value depends on the nature of the problem
pfloat optional The power of the Minkowski metric to be used to calculate distance between points

sampleweight array shape nsamples optional Weight of each sample such that a sample
with a weight of at least minsamples is by itself a core sample a sample with negative
weight may inhibit its epsneighbor from being core Note that weights are absolute and
default to 1
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details
Returns
coresamples array ncoresamples Indices of core samples
labels array nsamples Cluster labels for each point Noisy samples are given the label 1
See also
DBSCAN An estimator interface for this clustering algorithm
OPTICS A similar estimator interface clustering at multiple values of eps Our implementation is optimized
for memory usage
Notes
For an example see examplesclusterplotdbscanpy
This implementation bulkcomputes all neighborhood queries which increases the memory complexity to
Ond where d is the average number of neighbors while original DBSCAN had memory complexity On
It may attract a higher memory complexity when querying these nearest neighborhoods depending on the
algorithm
One way to avoid the query complexity is to precompute sparse neighborhoods in chunks
usingNearestNeighborsradiusneighborsgraph withmodedistance then using
metricprecomputed here
Another way to reduce memory and computation time is to remove nearduplicate points and use
sampleweight instead
clusteroptics provides a similar clustering with lower memory usage

sklearncluster estimatebandwidth
sklearncluster estimatebandwidth Xquantile03 nsamplesNone randomstate0
njobsNone
Estimate the bandwidth to use with the meanshift algorithm
That this function takes time at least quadratic in nsamples For large datasets it’s wise to set that parameter
to a small value

Parameters
Xarraylike shapensamples nfeatures Input points
quantile float default 03 should be between 0 1 05 means that the median of all pairwise distances is used
nsamples int optional The number of samples to use If not given all samples are used
randomstate int RandomState instance or None default The generator used to randomly select the samples from input points for bandwidth estimation Use an int to make the randomness deterministic See Glossary
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors searchNone means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
Returns
bandwidth float The bandwidth parameter
Examples using sklearnclusterestimatebandwidth
•A demo of the meanshift clustering algorithm
•Comparing different clustering algorithms on toy datasets
sklearncluster kmeans
sklearncluster kmeansXnclusters sampleweightNone init'kmeans' precom putedistances'auto' ninit10 maxiter300 verboseFalse tol00001 randomstateNone copyxTrue njobsNone algo rithm'auto' returnniterFalse
Kmeans clustering algorithm
Read more in the User Guide
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The observations to cluster It must be noted that the data will be converted to C ordering which will cause a memory copy if the given data is not Ccontiguous
nclusters int The number of clusters to form as well as the number of centroids to generate
sampleweight arraylike shape nsamples optional The weights for each observation in X If None all observations are assigned equal weight default None
init 'kmeans' 'random' or ndarray or a callable optional Method for initialization default to 'kmeans'
'kmeans' selects initial cluster centers for kmean clustering in a smart way to speed up convergence See section Notes in kinit for more details
'random' choose k observations rows at random from data for the initial centroids
If an ndarray is passed it should be of shape nclusters nfeatures and gives the initial centers
If a callable is passed it should take arguments X k and and a random state and return an initialization

precomputedistances ‘auto’ True False Precompute distances faster but takes more memory
‘auto’ do not precompute distances if nsamples nclusters 12 million This corresponds to about 100MB overhead per job using double precision
True always precompute distances
False never precompute distances
ninit int optional default 10 Number of time the kmeans algorithm will be run with different centroid seeds The final results will be the best output of ninit consecutive runs in terms of inertia
maxiter int optional default 300 Maximum number of iterations of the kmeans algorithm to run
verbose boolean optional Verbosity mode
tolfloat optional The relative increment in the results before declaring convergence
randomstate int RandomState instance or None default Determines random number generation for centroid initialization Use an int to make the randomness deterministic See Glossary
copyx boolean optional When precomputing distances it is more numerically accurate to center the data first If copyx is True default then the original data is not modified ensuring X is Ccontiguous If False the original data is modified and put back before the function returns but small numerical differences may be introduced by subtracting and then adding the data mean in this case it will also not ensure that data is Ccontiguous which may cause a significant slowdown
njobs int or None optional defaultNone The number of jobs to use for the computation This works by computing each of the ninit runs in parallel
None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
algorithm “auto” “full” or “elkan” default”auto” Kmeans algorithm to use The classical EMstyle algorithm is “full” The “elkan” variation is more efficient by using the triangle inequality but currently doesn’t support sparse data “auto” chooses “elkan” for dense data and “full” for sparse data
returnniter bool optional Whether or not to return the number of iterations
Returns
centroid float ndarray with shape k nfeatures Centroids found at the last iteration of k means
label integer ndarray with shape nsamples labeli is the code or index of the centroid the i’th observation is closest to
inertia float The final value of the inertia criterion sum of squared distances to the closest centroid for all observations in the training set
bestniter int Number of iterations corresponding to the best results Returned only if returnniter is set to True

sklearncluster meanshift
sklearncluster meanshift X bandwidthNone seedsNone binseedingFalse
minbinfreq1 clusterallTrue maxiter300 njobsNone
Perform mean shift clustering of data using a flat kernel
Read more in the User Guide
Parameters
Xarraylike shapensamples nfeatures Input data
bandwidth float optional Kernel bandwidth
If bandwidth is not given it is determined using a heuristic based on the median of
all pairwise distances This will take quadratic time in the number of samples The
sklearnclusterestimatebandwidth function can be used to do this more efficiently
seeds arraylike shapenseeds nfeatures or None Point used as initial kernel loca
tions If None and binseedingFalse each data point is used as a seed If None and
binseedingTrue see binseeding
binseeding boolean defaultFalse If true initial kernel locations are not locations of all
points but rather the location of the discretized version of points where points are binned
onto a grid whose coarseness corresponds to the bandwidth Setting this option to True will
speed up the algorithm because fewer seeds will be initialized Ignored if seeds argument is
not None
minbinfreq int default1 To speed up the algorithm accept only those bins with at least
minbinfreq points as seeds
clusterall boolean default True If true then all points are clustered even those orphans that
are not within any kernel Orphans are assigned to the nearest kernel If false then orphans
are given cluster label 1
maxiter int default 300 Maximum number of iterations per seed point before the clustering
operation terminates for that seed point if has not converged yet
njobs int or None optional defaultNone The number of jobs to use for the computation
This works by computing each of the ninit runs in parallel
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
New in version 017 Parallel Execution using njobs
Returns
clustercenters array shapenclusters nfeatures Coordinates of cluster centers
labels array shapensamples Cluster labels for each point
Notes
For an example see examplesclusterplotmeanshiftpy

sklearncluster spectralclustering
sklearncluster spectralclustering affinity nclusters8 ncomponentsNone
eigensolverNone randomstateNone ninit10
eigentol00 assignlabels'kmeans'
Apply clustering to a projection of the normalized Laplacian
In practice Spectral Clustering is very useful when the structure of the individual clusters is highly nonconvex
or more generally when a measure of the center and spread of the cluster is not a suitable description of the
complete cluster For instance when clusters are nested circles on the 2D plane
If affinity is the adjacency matrix of a graph this method can be used to find normalized graph cuts
Read more in the User Guide
Parameters
affinity arraylike or sparse matrix shape nsamples nsamples The affinity matrix de
scribing the relationship of the samples to embed Must be symmetric
Possible examples
• adjacency matrix of a graph
• heat kernel of the pairwise distance matrix of the samples
• symmetric knearest neighbours connectivity matrix of the samples
nclusters integer optional Number of clusters to extract
ncomponents integer optional default is nclusters Number of eigen vectors to use for the
spectral embedding
eigensolver None 'arpack' 'lobpcg' or 'amg' The eigenvalue decomposition strategy to
use AMG requires pyamg to be installed It can be faster on very large sparse problems
but may also lead to instabilities
randomstate int RandomState instance or None default A pseudo random number gener
ator used for the initialization of the lobpcg eigen vectors decomposition when eigensolver
 'amg' and by the KMeans initialization Use an int to make the randomness determin
istic See Glossary
ninit int optional default 10 Number of time the kmeans algorithm will be run with dif
ferent centroid seeds The final results will be the best output of ninit consecutive runs in
terms of inertia
eigentol float optional default 00 Stopping criterion for eigendecomposition of the Lapla
cian matrix when using arpack eigensolver
assignlabels 'kmeans' 'discretize' default 'kmeans' The strategy to use to assign labels
in the embedding space There are two ways to assign labels after the laplacian embedding
kmeans can be applied and is a popular choice But it can also be sensitive to initialization
Discretization is another approach which is less sensitive to random initialization See the
'Multiclass spectral clustering' paper referenced below for more details on the discretization
approach
Returns
labels array of integers shape nsamples The labels of the clusters

Notes
The graph should contain only one connect component elsewhere the results make little sense
This algorithm solves the normalized cut for k2 it is a normalized spectral clustering

sklearncluster wardtree
sklearncluster wardtree XconnectivityNone nclustersNone returndistanceFalse
Ward clustering based on a Feature matrix
Recursively merges the pair of clusters that minimally increases withincluster variance
The inertia matrix uses a Heapqbased representation
This is the structured version that takes into account some topological structure between samples
Read more in the User Guide
Parameters
Xarray shape nsamples nfeatures feature matrix representing nsamples samples to be
clustered
connectivity sparse matrix optional connectivity matrix Defines for each sample the neigh
boring samples following a given structure of the data The matrix is assumed to be sym
metric and only the upper triangular half is used Default is None ie the Ward algorithm is
unstructured
nclusters int optional Stop early the construction of the tree at nclusters This is useful
to decrease computation time if the number of clusters is not small compared to the number
of samples In this case the complete tree is not computed thus the ‘children’ output is of
limited use and the ‘parents’ output should rather be used This option is valid only when
specifying a connectivity matrix
returndistance bool optional If True return the distance between the clusters
Returns

children 2D array shape nnodes1 2 The children of each nonleaf node Values less
than nsamples correspond to leaves of the tree which are the original samples A node
igreater than or equal to nsamples is a nonleaf node and has children childreni
 nsamples Alternatively at the ith iteration childreni0 and childreni1 are
merged to form node nsamples i
nconnectedcomponents int The number of connected components in the graph
nleaves int The number of leaves in the tree
parents 1D array shape nnodes or None The parent of each node Only returned when a
connectivity matrix is specified elsewhere ‘None’ is returned
distances 1D array shape nnodes1 Only returned if returndistance is set to True for
compatibility The distances between the centers of the nodes distancesi cor
responds to a weighted euclidean distance between the nodes childreni 1 and
childreni 2 If the nodes refer to leaves of the tree then distancesi is
their unweighted euclidean distance Distances are updated in the following way from
scipyhierarchylinkage
The new entry □□ □is computed as follows
□□ □ √
□□
□□□ □2□□
□□□ □2−□
□□□ □2
where □is the newly joined cluster consisting of clusters □and□□is an unused cluster in
the forest □□□□ andis the cardinality of its argument This is also known
as the incremental algorithm

Spectral biclustering Kluger 2003
64sklearnclusterbicluster Biclustering 1517

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure For instance if there are two row partitions and three column partitions each row will belong to three biclusters and each column will belong to two biclusters The outer product of the corresponding row and column label vectors gives this checkerboard structure

Read more in the User Guide

Parameters

nclusters integer or tuple nrowclusters ncolumnclusters The number of row and col umn clusters in the checkerboard structure

method string optional default ‘bistochastic’ Method of normalizing and converting sin gular vectors into biclusters May be one of ‘scale’ ‘bistochastic’ or ‘log’ The authors recommend using ‘log’ If the data is sparse however log normalization will not work which is why the default is ‘bistochastic’ CAUTION if methodlog the data must not be sparse

ncomponents integer optional default 6 Number of singular vectors to check

nbest integer optional default 3 Number of best singular vectors to which to project the data for clustering

svdmethod string optional default ‘randomized’ Selects the algorithm for finding singu lar vectors May be ‘randomized’ or ‘arpack’ If ‘randomized’ uses sklearnutils extmathrandomizedsvd which may be faster for large matrices If ‘arpack’ uses scipysparselinalgsvds which is more accurate but possibly slower in some cases

nsvdvecs int optional default None Number of vectors to use in calculating the SVD Corresponds to ncv whensvdmethodarpack andnoversamples when svdmethod is ‘randomized‘

minibatch bool optional default False Whether to use minibatch kmeans which is faster but may get different results

init ‘kmeans’ ‘random’ or an ndarray Method for initialization of kmeans algorithm defaults to ‘kmeans’

ninit int optional default 10 Number of random initializations that are tried with the k means algorithm

If minibatch kmeans is used the best initialization is chosen and the algorithm runs once Otherwise the algorithm is run for each initialization and the best solution chosen

njobs int or None optional defaultNone The number of jobs to use for the computation This works by breaking down the pairwise matrix into njobs even slices and computing them in parallel

None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details

randomstate int RandomState instance or None default Used for randomizing the singular value decomposition and the kmeans initialization Use an int to make the randomness deterministic See Glossary

Attributes

65sklearncompose Composite Estimators
Metaestimators for building composite models with transformers
In addition to its current contents this module will eventually be home to refurbished versions of Pipeline and Fea
tureUnion
User guide See the Pipelines and composite estimators section for further details
composeColumnTransformer transformers Applies transformers to columns of an array or pandas
DataFrame
composeTransformedTargetRegressor Metaestimator to regress on a transformed target
651sklearncompose ColumnTransformer
classsklearncompose ColumnTransformer transformers remainder’drop’
sparsethreshold03 njobsNone trans
formerweightsNone verboseFalse
Applies transformers to columns of an array or pandas DataFrame
This estimator allows different columns or column subsets of the input to be transformed separately and the
features generated by each transformer will be concatenated to form a single feature space This is useful for
heterogeneous or columnar data to combine several feature extraction mechanisms or transformations into a
single transformer
Read more in the User Guide
New in version 020
Parameters
transformers list of tuples List of name transformer columns tuples specifying the trans
former objects to be applied to subsets of the data
name string Like in Pipeline and FeatureUnion this allows the transformer and its pa
rameters to be set using setparams and searched in grid search
transformer estimator or ‘passthrough’ ‘drop’ Estimator must support fit and
transform Specialcased strings ‘drop’ and ‘passthrough’ are accepted as well to
indicate to drop the columns or to pass them through untransformed respectively
columns string or int arraylike of string or int slice boolean mask array or callable
Indexes the data on its second axis Integers are interpreted as positional columns while
strings can reference DataFrame columns by name A scalar string or int should be used
wheretransformer expects X to be a 1d arraylike vector otherwise a 2d array will
be passed to the transformer A callable is passed the input data Xand can return any of
the above
remainder ‘drop’ ‘passthrough’ or estimator default ‘drop’ By default only the
specified columns in transformers are transformed and combined in the output and
the nonspecified columns are dropped default of drop By specifying
remainderpassthrough all remaining columns that were not specified in trans
formers will be automatically passed through This subset of columns is concatenated with
the output of the transformers By setting remainder to be an estimator the remaining
nonspecified columns will use the remainder estimator The estimator must support fit
andtransform Note that using this feature requires that the DataFrame columns input at fit
andtransform have identical order

sparsethreshold float default 03 If the output of the different transformers contains sparse
matrices these will be stacked as a sparse matrix if the overall density is lower than this
value Usesparsethreshold0 to always return dense When the transformed output
consists of all dense data the stacked result will be dense and this keyword will be ignored
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
transformerweights dict optional Multiplicative weights for features per transformer The
output of the transformer is multiplied by these weights Keys are transformer names values
the weights
verbose boolean optionaldefaultFalse If True the time elapsed while fitting each trans
former will be printed as it is completed
Attributes
transformers list The collection of fitted transformers as tuples of name fittedtransformer
columnfittedtransformer can be an estimator ‘drop’ or ‘passthrough’ In
case there were no columns selected this will be the unfitted transformer If there
are remaining columns the final element is a tuple of the form ‘remainder’ trans
former remainingcolumns corresponding to the remainder parameter If there are
remaining columns then lentransformerslentransformers1 other
wiselentransformerslentransformers
namedtransformers Bunch object a dictionary with attribute access Access the fitted
transformer by name
sparseoutput boolean Boolean flag indicating wether the output of transform is a sparse
matrix or a dense numpy array which depends on the output of the individual transformers
and thesparsethreshold keyword
See also
sklearncomposemakecolumntransformer convenience function for combining the outputs of
multiple transformer objects applied to column subsets of the original feature space
Notes
The order of the columns in the transformed feature matrix follows the order of how the columns are specified
in the transformers list Columns of the original feature matrix that are not specified are dropped from the
resulting transformed feature matrix unless specified in the passthrough keyword Those columns specified
withpassthrough are added at the right to the output of the transformers
Examples
```
 import numpy as np
 from sklearncompose import ColumnTransformer
 from sklearnpreprocessing import Normalizer
ct  ColumnTransformer
 norm1 Normalizernorml1 0 1
 norm2 Normalizernorml1 slice2 4
X  nparray0 1 2 2
 1 1 0 1
 Normalizer scales each row of X to unit norm A separate scaling
```

is applied for the two first and two last elements of each
row independently
ctfittransformX
array0 1 05 05
05 05 0 1
Methods
fitself X y Fit all transformers using X
fittransform self X y Fit all transformers transform the data and concatenate
results
getfeaturenames self Get feature names from all transformers
getparams self deep Get parameters for this estimator
setparams self kwargs Set the parameters of this estimator
transform self X Transform X separately by each transformer concate
nate results
init selftransformers remainder'drop' sparsethreshold03 njobsNone trans
formerweightsNone verboseFalse
fitselfXyNone
Fit all transformers using X
Parameters
Xarraylike or DataFrame of shape nsamples nfeatures Input data of which specified
subsets are used to fit the transformers
yarraylike shape nsamples optional Targets for supervised learning
Returns
self ColumnTransformer This estimator
fittransform selfXyNone
Fit all transformers transform the data and concatenate results
Parameters
Xarraylike or DataFrame of shape nsamples nfeatures Input data of which specified
subsets are used to fit the transformers
yarraylike shape nsamples optional Targets for supervised learning
Returns
Xt arraylike or sparse matrix shape nsamples sumncomponents hstack of results
of transformers sumncomponents is the sum of ncomponents output dimension over
transformers If any result is a sparse matrix everything will be converted to sparse matri
ces
getfeaturenames self
Get feature names from all transformers
Returns
featurenames list of strings Names of the features produced by transform

getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
namedtransformers
Access the fitted transformer by name
Readonly attribute to access any transformer by given name Keys are transformer names and values are
the fitted transformer objects
setparams selfkwargs
Set the parameters of this estimator
Valid parameter keys can be listed with getparams
Returns
self
transform selfX
Transform X separately by each transformer concatenate results
Parameters
Xarraylike or DataFrame of shape nsamples nfeatures The data to be transformed
by subset
Returns
Xt arraylike or sparse matrix shape nsamples sumncomponents hstack of results
of transformers sumncomponents is the sum of ncomponents output dimension over
transformers If any result is a sparse matrix everything will be converted to sparse matri
ces
Examples using sklearncomposeColumnTransformer
•Column Transformer with Mixed Types
•Column Transformer with Heterogeneous Data Sources
652sklearncompose TransformedTargetRegressor
classsklearncompose TransformedTargetRegressor regressorNone transformerNone
funcNone inversefuncNone
checkinverseTrue
Metaestimator to regress on a transformed target
Useful for applying a nonlinear transformation in regression problems This transformation can be given as a
Transformer such as the QuantileTransformer or as a function and its inverse such as log andexp
The computation during fit is
regressorfitX funcy

or
regressorfitX transformertransformy
The computation during predict is
inversefuncregressorpredictX
or
transformerinversetransformregressorpredictX
Read more in the User Guide
Parameters
regressor object defaultLinearRegression Regressor object such as derived from
RegressorMixin This regressor will automatically be cloned each time prior to fitting
transformer object defaultNone Estimator object such as derived from
TransformerMixin Cannot be set at the same time as func andinversefunc If
transformer isNone as well asfunc andinversefunc the transformer will be
an identity transformer Note that the transformer will be cloned during fitting Also the
transformer is restricting yto be a numpy array
func function optional Function to apply to ybefore passing to fit Cannot be set at the
same time as transformer The function needs to return a 2dimensional array If func
isNone the function used will be the identity function
inversefunc function optional Function to apply to the prediction of the regressor Can
not be set at the same time as transformer as well The function needs to return a
2dimensional array The inverse function is used to return predictions to the same space of
the original training labels
checkinverse bool defaultTrue Whether to check that transform followed by
inversetransform orfunc followed by inversefunc leads to the original tar
gets
Attributes
regressor object Fitted regressor
transformer object Transformer used in fit andpredict
Notes
Internally the target yis always converted into a 2dimensional array to be used by scikitlearn transformers
At the time of prediction the output will be reshaped to a have the same number of dimensions as y
Seeexamplescomposeplottransformedtargetpy
Examples
 import numpy as np

array2
Methods
fitself X y sampleweight Fit the model according to the given training data
getparams self deep Get parameters for this estimator
predict self X Predict using the base regressor applying inverse
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init self regressorNone transformerNone funcNone inversefuncNone
checkinverseTrue
fitselfXysampleweightNone
Fit the model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
sampleweight arraylike shape nsamples optional Array of weights that are assigned
to individual samples If not provided then each sample is given unit weight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the base regressor applying inverse
The regressor is used to predict and the inversefunc orinversetransform is applied before
returning the prediction
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Samples

Returns
yhat array shape nsamples Predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearncomposeTransformedTargetRegressor
•Effect of transforming the targets in regression model
composemakecolumntransformer Construct a ColumnTransformer from the given transform
ers
653sklearncompose makecolumntransformer
sklearncompose makecolumntransformer transformers kwargs
Construct a ColumnTransformer from the given transformers

This is a shorthand for the ColumnTransformer constructor it does not require and does not permit naming the transformers Instead they will be given names automatically based on their types It also does not allow weighting with transformerweights

Parameters

transformers tuples of transformers and column selections

remainder ‘drop’ ‘passthrough’ or estimator default ‘drop’ By default only the specified columns in transformers are transformed and combined in the output and the nonspecified columns are dropped default of drop By specifying remainderpassthrough all remaining columns that were not specified in trans formers will be automatically passed through This subset of columns is concatenated with the output of the transformers By setting remainder to be an estimator the remaining nonspecified columns will use the remainder estimator The estimator must support fit andtransform

sparsethreshold float default 03 If the transformed output consists of a mix of sparse and dense data it will be stacked as a sparse matrix if the density is lower than this value Use sparsethreshold0 to always return dense When the transformed output consists of all sparse or all dense data the stacked result will be sparse or dense respectively and this keyword will be ignored

njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details

verbose boolean optionaldefaultFalse If True the time elapsed while fitting each trans former will be printed as it is completed

Returns

ctColumnTransformer

See also

sklearncomposeColumnTransformer Class that allows combining the outputs of multiple trans former objects used on column subsets of the data into a single feature space

Examples

```

tor of covariance
covarianceOAS storeprecision Oracle Approximating Shrinkage Estimator
covarianceShrunkCovariance Covariance estimator with shrinkage
661sklearncovariance EmpiricalCovariance
classsklearncovariance EmpiricalCovariance storeprecisionTrue as
sumecenteredFalse
Maximum likelihood covariance estimator
Read more in the User Guide
Parameters
storeprecision bool Specifies if the estimated precision is stored
assumecentered bool If True data are not centered before computation Useful when work
ing with data whose mean is almost but not exactly zero If False default data are centered
before computation
Attributes
location arraylike shape nfeatures Estimated location ie the estimated mean
covariance 2D ndarray shape nfeatures nfeatures Estimated covariance matrix
precision 2D ndarray shape nfeatures nfeatures Estimated pseudoinverse matrix
stored only if storeprecision is True
Examples
 import numpy as np
 from sklearncovariance import EmpiricalCovariance
 from sklearndatasets import makegaussianquantiles

model according to the given training data and parame
ters
getparams self deep Get parameters for this estimator
getprecision self Getter for the precision matrix
mahalanobis self X Computes the squared Mahalanobis distances of given
observations
score self Xtest y Computes the loglikelihood of a Gaussian data set with
selfcovariance as an estimator of its covari
ance matrix
setparams self params Set the parameters of this estimator
init selfstoreprecisionTrue assumecenteredFalse
errornorm selfcompcov norm'frobenius' scalingTrue squaredTrue
Computes the Mean Squared Error between two covariance estimators In the sense of the Frobenius
norm
Parameters
compcov arraylike shape nfeatures nfeatures The covariance to compare with
norm str The type of norm used to compute the error Available error types 'frobenius'
default sqrttrAtA 'spectral' sqrtmaxeigenvaluesAtA where A is the error
compcov selfcovariance
scaling bool If True default the squared error norm is divided by nfeatures If False
the squared error norm is not rescaled
squared bool Whether to compute the squared error norm or the error norm If True
default the squared error norm is returned If False the error norm is returned
Returns
The Mean Squared Error in the sense of the Frobenius norm between
self andcompcov covariance estimators
fitselfXyNone
Fits the Maximum Likelihood Estimator covariance model according to the given training data and param
eters
Parameters

Xarraylike shape nsamples nfeatures Training data where nsamples is the num
ber of samples and nfeatures is the number of features
ynot used present for API consistence purpose
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Getter for the precision matrix
Returns
precision arraylike The precision matrix associated to the current covariance object
mahalanobis selfX
Computes the squared Mahalanobis distances of given observations
Parameters
Xarraylike shape nsamples nfeatures The observations the Mahalanobis distances
of the which we compute Observations are assumed to be drawn from the same distribu
tion than the data used in fit
Returns
dist array shape nsamples Squared Mahalanobis distances of the observations
scoreselfXtest yNone
Computes the loglikelihood of a Gaussian data set with selfcovariance as an estimator of its
covariance matrix
Parameters
Xtest arraylike shape nsamples nfeatures Test data of which we compute the
likelihood where nsamples is the number of samples and nfeatures is the number of
features Xtest is assumed to be drawn from the same distribution than the data used in
fit including centering
ynot used present for API consistence purpose
Returns
resfloat The likelihood of the data set with selfcovariance as an estimator of its
covariance matrix
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object

Returns
self
Examples using sklearncovarianceEmpiricalCovariance
•Robust covariance estimation and Mahalanobis distances relevance
•Robust vs Empirical covariance estimate
662sklearncovariance EllipticEnvelope
classsklearncovariance EllipticEnvelope storeprecisionTrue assumecenteredFalse
supportfractionNone contamination01
randomstateNone
An object for detecting outliers in a Gaussian distributed dataset
Read more in the User Guide
Parameters
storeprecision boolean optional defaultTrue Specify if the estimated precision is stored
assumecentered boolean optional defaultFalse If True the support of robust location and
covariance estimates is computed and a covariance estimate is recomputed from it without
centering the data Useful to work with data whose mean is significantly equal to zero but is
not exactly zero If False the robust location and covariance are directly computed with the
FastMCD algorithm without additional treatment
supportfraction float in 0 1 optional defaultNone The proportion of points to be
included in the support of the raw MCD estimate If None the minimum value of sup
portfraction will be used within the algorithm nsample nfeatures 1
 2
contamination float in 0 05 optional default01 The amount of contamination of the
data set ie the proportion of outliers in the data set
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator to use when shuffling the data If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
Attributes
location arraylike shape nfeatures Estimated robust location
covariance arraylike shape nfeatures nfeatures Estimated robust covariance matrix
precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix stored
only if storeprecision is True
support arraylike shape nsamples A mask of the observations that have been used to
compute the robust estimates of location and shape
offset float Offset used to define the decision function from the raw scores We have the rela
tiondecisionfunction scoresamples offset The offset depends
on the contamination parameter and is defined in such a way we obtain the expected number
of outliers samples with decision function 0 in training

Table 634 – continued from previous page
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
scoresamples self X Compute the negative Mahalanobis distances
setparams self params Set the parameters of this estimator
init selfstoreprecisionTrue assumecenteredFalse supportfractionNone contamina
tion01 randomstateNone
correctcovariance selfdata
Apply a correction to raw Minimum Covariance Determinant estimates
Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in RVD
Parameters
data arraylike shape nsamples nfeatures The data matrix with p features and n sam
ples The data set must be the one which was used to compute the raw estimates
Returns
covariancecorrected arraylike shape nfeatures nfeatures Corrected robust covari
ance estimate
References
RVD
decisionfunction selfXrawvaluesNone
Compute the decision function of the given observations
Parameters
Xarraylike shape nsamples nfeatures
rawvalues bool optional Whether or not to consider raw Mahalanobis distances as the
decision function Must be False default for compatibility with the others outlier detec
tion tools
Deprecated since version 020 rawvalues has been deprecated in 020 and will be
removed in 022
Returns
decision arraylike shape nsamples Decision function of the samples It is equal to
the shifted Mahalanobis distances The threshold for being an outlier is 0 which ensures
a compatibility with other outlier detection algorithms
errornorm selfcompcov norm'frobenius' scalingTrue squaredTrue
Computes the Mean Squared Error between two covariance estimators In the sense of the Frobenius
norm
Parameters
compcov arraylike shape nfeatures nfeatures The covariance to compare with
norm str The type of norm used to compute the error Available error types 'frobenius'
default sqrttrAtA 'spectral' sqrtmaxeigenvaluesAtA where A is the error
compcov selfcovariance
scaling bool If True default the squared error norm is divided by nfeatures If False
the squared error norm is not rescaled

squared bool Whether to compute the squared error norm or the error norm If True
default the squared error norm is returned If False the error norm is returned
Returns
The Mean Squared Error in the sense of the Frobenius norm between
self andcompcov covariance estimators
fitselfXyNone
Fit the EllipticEnvelope model
Parameters
Xnumpy array or sparse matrix shape nsamples nfeatures Training data
yIgnored not used present for API consistency by convention
fitpredict selfXyNone
Performs fit on X and returns labels for X
Returns 1 for outliers and 1 for inliers
Parameters
Xndarray shape nsamples nfeatures Input data
yIgnored not used present for API consistency by convention
Returns
yndarray shape nsamples 1 for inliers 1 for outliers
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Getter for the precision matrix
Returns
precision arraylike The precision matrix associated to the current covariance object
mahalanobis selfX
Computes the squared Mahalanobis distances of given observations
Parameters
Xarraylike shape nsamples nfeatures The observations the Mahalanobis distances
of the which we compute Observations are assumed to be drawn from the same distribu
tion than the data used in fit
Returns
dist array shape nsamples Squared Mahalanobis distances of the observations
predictselfX
Predict the labels 1 inlier 1 outlier of X according to the fitted model

Parameters
Xarraylike shape nsamples nfeatures
Returns
isinlier array shape nsamples Returns 1 for anomaliesoutliers and 1 for inliers
reweightcovariance selfdata
Reweight raw Minimum Covariance Determinant estimates
Reweight observations using Rousseeuw's method equivalent to deleting outlying observations from the
data set before computing location and covariance estimates described in RVDriessen
Parameters
data arraylike shape nsamples nfeatures The data matrix with p features and n sam
ples The data set must be the one which was used to compute the raw estimates
Returns
locationreweighted arraylike shape nfeatures Reweighted robust location esti
mate
covariancereweighted arraylike shape nfeatures nfeatures Reweighted robust co
variance estimate
supportreweighted arraylike type boolean shape nsamples A mask of the obser
vations that have been used to compute the reweighted robust location and covariance
estimates
References
RVDriessen
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
scoresamples selfX
Compute the negative Mahalanobis distances
Parameters
Xarraylike shape nsamples nfeatures
Returns
negativemahaldistances arraylike shape nsamples Opposite of the Mahalanobis
distances

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
Examples using sklearncovarianceEllipticEnvelope
•Comparing anomaly detection algorithms for outlier detection on toy datasets
•Outlier detection on a real data set
663sklearncovariance GraphicalLasso
classsklearncovariance GraphicalLasso alpha001 mode’cd’ tol00001 enettol00001 maxiter100 verboseFalse assumecenteredFalse
Sparse inverse covariance estimation with an l1penalized estimator
Read more in the User Guide
Parameters
alpha positive float default 001 The regularization parameter the higher alpha the more regularization the sparser the inverse covariance
mode ‘cd’ ‘lars’ default ‘cd’ The Lasso solver to use coordinate descent or LARS Use LARS for very sparse underlying graphs where p n Elsewhere prefer cd which is more numerically stable
tolpositive float default 1e4 The tolerance to declare convergence if the dual gap goes below this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate the descent direction This parameter controls the accuracy of the search direction for a given column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer default 100 The maximum number of iterations
verbose boolean default False If verbose is True the objective function and dual gap are plotted at each iteration
assumecentered boolean default False If True data are not centered before computation Useful when working with data whose mean is almost but not exactly zero If False data are centered before computation
Attributes
location arraylike shape nfeatures Estimated location ie the estimated mean
covariance arraylike shape nfeatures nfeatures Estimated covariance matrix
precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix
niter int Number of iterations run

sumecenteredFalse
Sparse inverse covariance w crossvalidated choice of the l1 penalty
See glossary entry for crossvalidation estimator
Read more in the User Guide
Parameters
alphas integer or list positive float optional If an integer is given it fixes the number of points
on the grids of alpha to be used If a list is given it gives the grid to be used See the notes
in the class docstring for more details
nrefinements strictly positive integer The number of times the grid is refined Not used if
explicit values of alphas are passed
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
tolpositive float optional The tolerance to declare convergence if the dual gap goes below
this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate the
descent direction This parameter controls the accuracy of the search direction for a given
column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer optional Maximum number of iterations

mode ‘cd’ ‘lars’ The Lasso solver to use coordinate descent or LARS Use LARS for
very sparse underlying graphs where number of features is greater than number of samples
Elsewhere prefer cd which is more numerically stable
njobs int or None optional defaultNone number of jobs to run in parallel None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
verbose boolean optional If verbose is True the objective function and duality gap are printed
at each iteration
assumecentered boolean If True data are not centered before computation Useful when
working with data whose mean is almost but not exactly zero If False data are centered
before computation
Attributes
location arraylike shape nfeatures Estimated location ie the estimated mean
covariance numpyndarray shape nfeatures nfeatures Estimated covariance matrix
precision numpyndarray shape nfeatures nfeatures Estimated precision matrix inverse
covariance
alpha float Penalization parameter selected
cvalphas list of float All penalization parameters explored
gridscores 2D numpyndarray nalphas nfolds Loglikelihood score on leftout data
across folds
niter int Number of iterations run for the optimal alpha
See also
graphicallasso GraphicalLasso
Notes
The search for the optimal penalization parameter alpha is done on an iteratively refined grid first the cross
validated scores on a grid are computed then a new refined grid is centered around the maximum and so on
One of the challenges which is faced here is that the solvers can fail to converge to a wellconditioned estimate
The corresponding values of alpha then come out as missing values but the optimum may be close to these
missing values

errornorm selfcompcov norm'frobenius' scalingTrue squaredTrue
Computes the Mean Squared Error between two covariance estimators In the sense of the Frobenius
norm
Parameters
compcov arraylike shape nfeatures nfeatures The covariance to compare with
norm str The type of norm used to compute the error Available error types 'frobenius'
default sqrttrAtA 'spectral' sqrtmaxeigenvaluesAtA where A is the error
compcov selfcovariance
scaling bool If True default the squared error norm is divided by nfeatures If False
the squared error norm is not rescaled
squared bool Whether to compute the squared error norm or the error norm If True
default the squared error norm is returned If False the error norm is returned
Returns
The Mean Squared Error in the sense of the Frobenius norm between
self andcompcov covariance estimators
fitselfXyNone
Fits the GraphicalLasso covariance model to X
Parameters
Xndarray shape nsamples nfeatures Data from which to compute the covariance es
timate
yignored

getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Getter for the precision matrix
Returns
precision arraylike The precision matrix associated to the current covariance object
mahalanobis selfX
Computes the squared Mahalanobis distances of given observations
Parameters
Xarraylike shape nsamples nfeatures The observations the Mahalanobis distances
of the which we compute Observations are assumed to be drawn from the same distribu
tion than the data used in fit
Returns
dist array shape nsamples Squared Mahalanobis distances of the observations
scoreselfXtest yNone
Computes the loglikelihood of a Gaussian data set with selfcovariance as an estimator of its
covariance matrix
Parameters
Xtest arraylike shape nsamples nfeatures Test data of which we compute the
likelihood where nsamples is the number of samples and nfeatures is the number of
features Xtest is assumed to be drawn from the same distribution than the data used in
fit including centering
ynot used present for API consistence purpose
Returns
resfloat The likelihood of the data set with selfcovariance as an estimator of its
covariance matrix
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

665sklearncovariance LedoitWolf
classsklearncovariance LedoitWolf storeprecisionTrue assumecenteredFalse
blocksize1000
LedoitWolf Estimator
LedoitWolf is a particular form of shrinkage where the shrinkage coefficient is computed using O Ledoit and
M Wolf’s formula as described in “A WellConditioned Estimator for LargeDimensional Covariance Matrices”
Ledoit and Wolf Journal of Multivariate Analysis V olume 88 Issue 2 February 2004 pages 365411
Read more in the User Guide
Parameters
storeprecision bool defaultTrue Specify if the estimated precision is stored
assumecentered bool defaultFalse If True data will not be centered before computation
Useful when working with data whose mean is almost but not exactly zero If False de
fault data will be centered before computation
blocksize int default1000 Size of the blocks into which the covariance matrix will be split
during its LedoitWolf estimation This is purely a memory optimization and does not affect
results
Attributes
location arraylike shape nfeatures Estimated location ie the estimated mean
covariance arraylike shape nfeatures nfeatures Estimated covariance matrix
precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix stored
only if storeprecision is True
shrinkage float 0 shrinkage 1 Coefficient in the convex combination used for the
computation of the shrunk estimate
Notes
The regularised covariance is
1 shrinkage cov shrinkage mu npidentitynfeatures
where mu tracecov nfeatures and shrinkage is given by the Ledoit and Wolf formula see References

classsklearncovariance MinCovDet storeprecisionTrue assumecenteredFalse sup
portfractionNone randomstateNone
Minimum Covariance Determinant MCD robust estimator of covariance
The Minimum Covariance Determinant covariance estimator is to be applied on Gaussiandistributed data but
could still be relevant on data drawn from a unimodal symmetric distribution It is not meant to be used with
multimodal data the algorithm used to fit a MinCovDet object is likely to fail in such a case One should
consider projection pursuit methods to deal with multimodal datasets
Read more in the User Guide
Parameters
storeprecision bool Specify if the estimated precision is stored
assumecentered bool If True the support of the robust location and the covariance estimates
is computed and a covariance estimate is recomputed from it without centering the data
Useful to work with data whose mean is significantly equal to zero but is not exactly zero If
False the robust location and covariance are directly computed with the FastMCD algorithm
without additional treatment
supportfraction float 0 supportfraction 1 The proportion of points to be included in
the support of the raw MCD estimate Default is None which implies that the minimum
value of supportfraction will be used within the algorithm nsample nfeatures 1 2
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Attributes
rawlocation arraylike shape nfeatures The raw robust estimated location before cor
rection and reweighting
rawcovariance arraylike shape nfeatures nfeatures The raw robust estimated covari
ance before correction and reweighting
rawsupport arraylike shape nsamples A mask of the observations that have been
used to compute the raw robust estimates of location and shape before correction and re
weighting
location arraylike shape nfeatures Estimated robust location
covariance arraylike shape nfeatures nfeatures Estimated robust covariance matrix

precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix stored
only if storeprecision is True
support arraylike shape nsamples A mask of the observations that have been used to
compute the robust estimates of location and shape
dist arraylike shape nsamples Mahalanobis distances of the training set on which fit
is called observations

•Robust vs Empirical covariance estimate
667sklearncovariance OAS
classsklearncovariance OASstoreprecisionTrue assumecenteredFalse
Oracle Approximating Shrinkage Estimator
Read more in the User Guide
OAS is a particular form of shrinkage described in “Shrinkage Algorithms for MMSE Covariance Estimation”
Chen et al IEEE Trans on Sign Proc V olume 58 Issue 10 October 2010
The formula used here does not correspond to the one given in the article In the original article formula 23
states that 2p is multiplied by Tracecovcov in both the numerator and denominator but this operation is
omitted because for a large p the value of 2p is so small that it doesn’t affect the value of the estimator
Parameters
storeprecision bool defaultTrue Specify if the estimated precision is stored
assumecentered bool defaultFalse If True data will not be centered before computation
Useful when working with data whose mean is almost but not exactly zero If False de
fault data will be centered before computation
Attributes
covariance arraylike shape nfeatures nfeatures Estimated covariance matrix
precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix stored
only if storeprecision is True
shrinkage float 0 shrinkage 1 coefficient in the convex combination used for the
computation of the shrunk estimate

Notes
The regularised covariance is
1 shrinkage cov shrinkage mu npidentitynfeatures
where mu tracecov nfeatures and shrinkage is given by the OAS formula see References

Parameters
empcov 2D ndarray shape nfeatures nfeatures Empirical covariance from which to
compute the covariance estimate
alpha positive float The regularization parameter the higher alpha the more regularization
the sparser the inverse covariance
covinit 2D array nfeatures nfeatures optional The initial guess for the covariance
mode ‘cd’ ‘lars’ The Lasso solver to use coordinate descent or LARS Use LARS for
very sparse underlying graphs where p n Elsewhere prefer cd which is more numerically
stable
tolpositive float optional The tolerance to declare convergence if the dual gap goes below
this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate the
descent direction This parameter controls the accuracy of the search direction for a given
column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer optional The maximum number of iterations
verbose boolean optional If verbose is True the objective function and dual gap are printed
at each iteration
returncosts boolean optional If returncosts is True the objective function and dual gap at
each iteration are returned
eps float optional The machineprecision regularization in the computation of the Cholesky
diagonal factors Increase this for very illconditioned systems
returnniter bool optional Whether or not to return the number of iterations
Returns
covariance 2D ndarray shape nfeatures nfeatures The estimated covariance matrix
precision 2D ndarray shape nfeatures nfeatures The estimated sparse precision matrix
costs list of objective dualgap pairs The list of values of the objective function and the dual
gap at each iteration Returned only if returncosts is True
niter int Number of iterations Returned only if returnniter is set to True

GraphicalLasso GraphicalLassoCV
Notes
The algorithm employed to solve this problem is the GLasso algorithm from the Friedman 2008 Biostatistics
paper It is the same algorithm as in the R glasso package
One possible difference with the glasso R package is that the diagonal coefficients are not penalized

6611sklearncovariance ledoitwolf
sklearncovariance ledoitwolf XassumecenteredFalse blocksize1000
Estimates the shrunk LedoitWolf covariance matrix
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures Data from which to compute the covariance esti
mate
assumecentered boolean defaultFalse If True data will not be centered before computa
tion Useful to work with data whose mean is significantly equal to zero but is not exactly
zero If False data will be centered before computation
blocksize int default1000 Size of the blocks into which the covariance matrix will be split
This is purely a memory optimization and does not affect results
Returns
shrunkcov arraylike shape nfeatures nfeatures Shrunk covariance
shrinkage float Coefficient in the convex combination used for the computation of the shrunk
estimate
Notes
The regularized shrunk covariance is
1 shrinkage cov shrinkage mu npidentitynfeatures
where mu tracecov nfeatures
Examples using sklearncovarianceledoitwolf
•Sparse inverse covariance estimation
6612sklearncovariance oas
sklearncovariance oasXassumecenteredFalse
Estimate covariance with the Oracle Approximating Shrinkage algorithm
Parameters
Xarraylike shape nsamples nfeatures Data from which to compute the covariance esti
mate
assumecentered boolean If True data will not be centered before computation Useful to
work with data whose mean is significantly equal to zero but is not exactly zero If False
data will be centered before computation
Returns
shrunkcov arraylike shape nfeatures nfeatures Shrunk covariance
shrinkage float Coefficient in the convex combination used for the computation of the shrunk
estimate

Notes
The regularised shrunk covariance is
1 shrinkage cov shrinkage mu npidentitynfeatures
where mu tracecov nfeatures
The formula we used to implement the OAS is slightly modified compared to the one given in the article See
OAS for more details
6613sklearncovariance shrunkcovariance
sklearncovariance shrunkcovariance empcov shrinkage01
Calculates a covariance matrix shrunk on the diagonal
Read more in the User Guide
Parameters
empcov arraylike shape nfeatures nfeatures Covariance matrix to be shrunk
shrinkage float 0 shrinkage 1 Coefficient in the convex combination used for the
computation of the shrunk estimate
Returns
shrunkcov arraylike Shrunk covariance
Notes
The regularized shrunk covariance is given by
1 shrinkage cov shrinkage mu npidentitynfeatures
where mu tracecov nfeatures

subobjects that are estimators
```

Returns
params mapping of string to any Parameter names mapped to their values
predictselfXcopyTrue
Apply the dimension reduction learned on the train data
Parameters
Xarraylike shape nsamples nfeatures Training vectors where nsamples is the
number of samples and nfeatures is the number of predictors
copy boolean default True Whether to copy X and Y or perform inplace normalization
Notes
This call requires the estimation of a p x q matrix which may be an issue in high dimensional space
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfXYNone copyTrue
Apply the dimension reduction learned on the train data
Parameters
Xarraylike shape nsamples nfeatures Training vectors where nsamples is the
number of samples and nfeatures is the number of predictors
Yarraylike shape nsamples ntargets Target vectors where nsamples is the num
ber of samples and ntargets is the number of response variables
copy boolean default True Whether to copy X and Y or perform inplace normalization
Returns
xscores if Y is not given xscores yscores otherwise

classsklearncrossdecomposition PLSCanonical ncomponents2 scaleTrue algo
rithm’nipals’ maxiter500 tol1e06
copyTrue
PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm Tenenhaus 1998 p204
referred as PLSC2A in Wegelin 2000
This class inherits from PLS with mode”A” and deflationmode”canonical” normyweightsTrue and al
gorithm”nipals” but svd should provide similar results up to numerical errors
Read more in the User Guide
Parameters
ncomponents int default 2 Number of components to keep
scale boolean default True Option to scale data
algorithm string “nipals” or “svd” The algorithm used to estimate the weights It will be
called ncomponents times ie once for each iteration of the outer loop
maxiter an integer default 500 the maximum number of iterations of the NIPALS inner
loop used only if algorithm”nipals”
tolnonnegative real default 1e06 the tolerance used in the iterative algorithm
copy boolean default True Whether the deflation should be done on a copy Let the default
value to True unless you don’t care about side effect
Attributes
xweights array shape p ncomponents X block weights vectors
yweights array shape q ncomponents Y block weights vectors
xloadings array shape p ncomponents X block loadings vectors
yloadings array shape q ncomponents Y block loadings vectors
xscores array shape nsamples ncomponents X scores
67sklearncrossdecomposition Cross decomposition 1567

yscores array shape nsamples ncomponents Y scores
xrotations array shape p ncomponents X block to latents rotations
yrotations array shape q ncomponents Y block to latents rotations
niter arraylike Number of iterations of the NIPALS inner loop for each component Not
useful if the algorithm provided is “svd”

Notes
Matrices
T xscores
U yscores
W xweights
C yweights
P xloadings
Q yloadings
Are computed such that
X T PT Err andY U QT Err
T k Xk W k forkinrangencomponents
U k Yk C k forkinrangencomponents
xrotations W PT W1
yrotations C QT C1
where Xk and Yk are residual matrices at iteration k
Slides explaining PLS
For each component k find weights u v that optimize
max corrXk u Yk v stdXk u stdYk u such that u v 1
Note that it maximizes both the correlations between the scores and the intrablock variances
The residual matrix of X Xk1 block is obtained by the deflation on the current X score xscore
The residual matrix of Y Yk1 block is obtained by deflation on the current Y score This performs a canonical
symmetric version of the PLS regression But slightly different than the CCA This is mostly used for modeling
This implementation provides the same results that the “plspm” package provided in the R language R
project using the function plscaX Y Results are equal or collinear with the function pls mode
 canonical of the “mixOmics” package The difference relies in the fact that mixOmics implementa
tion does not exactly implement the Wold algorithm since it does not normalize yweights to one

sklearndatasets cleardatahome
sklearndatasets cleardatahome datahomeNone
Delete all the content of the data home cache
Parameters
datahome str None The path to scikitlearn data dir
sklearndatasets dumpsvmlightfile
sklearndatasets dumpsvmlightfile Xy f zerobasedTrue commentNone
queryidNone multilabelFalse
Dump the dataset in svmlight libsvm file format
This format is a textbased format with one sample per line It does not store zero valued features hence is
suitable for sparse dataset
The first element of each line can be used to store a target variable to predict
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features
yarraylike sparse matrix shape nsamples nlabels Target values Class labels
must be an integer or float or arraylike objects of integer or float for multilabel classifica
tions
fstring or filelike in binary mode If string specifies the path that will contain the data If
filelike data will be written to f f should be opened in binary mode
zerobased boolean optional Whether column indices should be written zerobased True or
onebased False
comment string optional Comment to insert at the top of the file This should be either a
Unicode string which will be encoded as UTF8 or an ASCII byte string If a comment

is given then it will be preceded by one that identifies the file as having been dumped by scikitlearn Note that not all tools grok comments in SVMlight files
queryid arraylike shape nsamples Array containing pairwise preference constraints qid in svmlight format
multilabel boolean optional Samples may have several labels each see httpswwwcsientu edutwcjlinlibsvmtoolsdatasetsmultilabelhtml
New in version 017 parameter multilabel to support multilabel datasets

Read more in the User Guide
Parameters
datahome optional default None Specify a download and cache folder for the datasets If None all scikitlearn data is stored in ‘scikitlearndata’ subfolders
subset ‘train’ or ‘test’ ‘all’ optional Select the dataset to load ‘train’ for the training set ‘test’ for the test set ‘all’ for both with shuffled ordering
categories None or collection of string or unicode If None default load all the categories If not None list of category names to load other categories ignored
shuffle bool optional Whether or not to shuffle the data might be important for models that make the assumption that the samples are independent and identically distributed iid such as stochastic gradient descent
randomstate int RandomState instance or None default Determines random number gen eration for dataset shuffling Pass an int for reproducible output across multiple function calls See Glossary
remove tuple May contain any subset of ‘headers’ ‘footers’ ‘quotes’ Each of these are kinds of text that will be detected and removed from the newsgroup posts preventing clas sifiers from overfitting on metadata
‘headers’ removes newsgroup headers ‘footers’ removes blocks at the ends of posts that look like signatures and ‘quotes’ removes lines that appear to be quoting another post ‘headers‘ follows an exact standard the other filters are not always correct

downloadifmissing optional True by default If False raise an IOError if the data is not
locally available instead of trying to download the data from the source site
Returns
bunch Bunch object with the following attribute
• bunchdata list length nsamples
• bunchtarget array shape nsamples
• bunchfilenames list length nsamples
• bunchDESCR a description of the dataset
• bunchtargetnames a list of categories of the returned data length nclasses This
depends on the categories parameter
Examples using sklearndatasetsfetch20newsgroups
•Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet Allocation
•Biclustering documents with the Spectral Coclustering algorithm
•Column Transformer with Heterogeneous Data Sources
•Sample pipeline for text feature extraction and evaluation
•FeatureHasher and DictVectorizer Comparison
•Clustering text documents using kmeans
•Classification of text documents using sparse features
sklearndatasets fetch20newsgroupsvectorized
sklearndatasets fetch20newsgroupsvectorized subset’train’ remove
datahomeNone down
loadifmissingTrue re
turnXyFalse
Load the 20 newsgroups dataset and vectorize it into token counts classification
Download it if necessary
This is a convenience function the transformation is done using the default settings for sklearn
featureextractiontextCountVectorizer For more advanced usage stopword
filtering ngram extraction etc combine fetch20newsgroups with a custom sklearn
featureextractiontextCountVectorizer sklearnfeatureextractiontext
HashingVectorizer sklearnfeatureextractiontextTfidfTransformer or
sklearnfeatureextractiontextTfidfVectorizer
Classes 20
Samples total 18846

Parameters

scikitlearn user guide Release 0213
subset ‘train’ or ‘test’ ‘all’ optional Select the dataset to load ‘train’ for the training set ‘test’ for the test set ‘all’ for both with shuffled ordering
remove tuple May contain any subset of ‘headers’ ‘footers’ ‘quotes’ Each of these are kinds of text that will be detected and removed from the newsgroup posts preventing classifiers from overfitting on metadata
‘headers’ removes newsgroup headers ‘footers’ removes blocks at the ends of posts that look like signatures and ‘quotes’ removes lines that appear to be quoting another post
datahome optional default None Specify an download and cache folder for the datasets If None all scikitlearn data is stored in ‘scikitlearndata’ subfolders
downloadifmissing optional True by default If False raise an IOError if the data is not locally available instead of trying to download the data from the source site
returnXy boolean defaultFalse If True returns datadata datatarget instead of a Bunch object
New in version 020
Returns
bunch Bunch object with the following attribute
• bunchdata sparse matrix shape nsamples nfeatures
• bunchtarget array shape nsamples
• bunchtargetnames a list of categories of the returned data length nclasses
• bunchDESCR a description of the dataset
data target tuple ifreturnXy is True New in version 020
Examples using sklearndatasetsfetch20newsgroupsvectorized
•The JohnsonLindenstrauss bound for embedding with random projections
•Model Complexity Influence
•Multiclass sparse logisitic regression on newgroups20
sklearndatasets fetchcaliforniahousing
sklearndatasets fetchcaliforniahousing datahomeNone downloadifmissingTrue returnXyFalse
Load the California housing dataset regression
Samples total 20640
Dimensionality 8
Features real
Target real 015 5
Read more in the User Guide
Parameters
datahome optional default None Specify another download and cache folder for the datasets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders

downloadifmissing optional defaultTrue If False raise a IOError if the data is not locally available instead of trying to download the data from the source site
returnXy boolean defaultFalse If True returns datadata datatarget in stead of a Bunch object
New in version 020
Returns
dataset dictlike object with the following attributes
datasetdata ndarray shape 20640 8 Each row corresponding to the 8 feature values in order
datasettarget numpy array of shape 20640 Each value corresponds to the average house value in units of 100000
datasetfeaturenames array of length 8 Array of ordered feature names used in the dataset
datasetDESCR string Description of the California housing dataset
data target tuple ifreturnXy is True New in version 020
Notes
This dataset consists of 20640 samples and 9 features
Examples using sklearndatasetsfetchcaliforniahousing
•Imputing missing values with variants of IterativeImputer
•Partial Dependence Plots
•Compare the effect of different scalers on data with outliers
sklearndatasets fetchcovtype
sklearndatasets fetchcovtype datahomeNone downloadifmissingTrue ran domstateNone shuffleFalse returnXyFalse
Load the covertype dataset classification

Load the Labeled Faces in the Wild LFW pairs dataset classification
Download it if necessary
Classes 5749
Samples total 13233
Dimensionality 5828
Features real between 0 and 255
In the official READMEtxt this task is described as the “Restricted” task As I am not sure as to implement the
“Unrestricted” variant correctly I left it as unsupported for now
The original images are 250 x 250 pixels but the default slice and resize arguments reduce them to 62 x 47
Read more in the User Guide
Parameters
subset optional default ‘train’ Select the dataset to load ‘train’ for the development training
set ‘test’ for the development test set and ‘10folds’ for the official evaluation set that is
meant to be used with a 10folds cross validation
datahome optional default None Specify another download and cache folder for the
datasets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders
funneled boolean optional default True Download and use the funneled variant of the
dataset
resize float optional default 05 Ratio used to resize the each face picture
color boolean optional default False Keep the 3 RGB channels instead of averaging them to
a single gray level channel If color is True the shape of the data has one more dimension
than the shape with color False
slice optional Provide a custom 2D slice height width to extract the ‘interesting’ part of
the jpeg files and avoid use statistical correlation from the background

scikitlearn user guide Release 0213
downloadifmissing optional True by default If False raise a IOError if the data is not locally available instead of trying to download the data from the source site
Returns
The data is returned as a Bunch object with the following attributes
data numpy array of shape 2200 5828 Shape depends on subset Each row corresponds to 2 ravel'd face images of original size 62 x 47 pixels Changing the slice resize or subset parameters will change the shape of the output
pairs numpy array of shape 2200 2 62 47 Shape depends on subset Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people Changing the slice resize orsubset parameters will change the shape of the output
target numpy array of shape 2200 Shape depends on subset Labels associated to each pair of images The two label values being different persons or the same person
DESCR string Description of the Labeled Faces in the Wild LFW dataset
sklearndatasets fetchlfwpeople
sklearndatasets fetchlfwpeople datahomeNone funneledTrue resize05 minfacesperperson0 colorFalse sliceslice70 195 None slice78 172 None down loadifmissingTrue returnXyFalse
Load the Labeled Faces in the Wild LFW people dataset classification
Download it if necessary
Classes 5749

Parameters
datahome optional default None Specify another download and cache folder for the datasets By default all scikitlearn data is stored in 'scikitlearndata' subfolders
funneled boolean optional default True Download and use the funneled variant of the dataset
resize float optional default 05 Ratio used to resize the each face picture
minfacesperperson int optional default None The extracted dataset will only retain pic tures of people that have at least minfacesperperson different pictures
color boolean optional default False Keep the 3 RGB channels instead of averaging them to a single gray level channel If color is True the shape of the data has one more dimension than the shape with color False
slice optional Provide a custom 2D slice height width to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background
downloadifmissing optional True by default If False raise a IOError if the data is not locally available instead of trying to download the data from the source site

returnXy boolean defaultFalse If True returns datasetdata dataset
target instead of a Bunch object See below for more information about the dataset
data anddatasettarget object
New in version 020
Returns
dataset dictlike object with the following attributes
datasetdata numpy array of shape 13233 2914 Each row corresponds to a ravelled face
image of original size 62 x 47 pixels Changing the slice or resize parameters will
change the shape of the output
datasetimages numpy array of shape 13233 62 47 Each row is a face image corresponding
to one of the 5749 people in the dataset Changing the slice or resize parameters will
change the shape of the output
datasettarget numpy array of shape 13233 Labels associated to each face image Those
labels range from 05748 and correspond to the person IDs
datasetDESCR string Description of the Labeled Faces in the Wild LFW dataset
data target tuple ifreturnXy is True New in version 020
Examples using sklearndatasetsfetchlfwpeople
•Faces recognition example using eigenfaces and SVMs
sklearndatasets fetcholivettifaces
sklearndatasets fetcholivettifaces datahomeNone shuffleFalse randomstate0
downloadifmissingTrue
Load the Olivetti faces dataset from ATT classification
Download it if necessary
Classes 40
Samples total 400
Dimensionality 4096
Features real between 0 and 1
Read more in the User Guide
Parameters
datahome optional default None Specify another download and cache folder for the
datasets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders
shuffle boolean optional If True the order of the dataset is shuffled to avoid having images of
the same person grouped
randomstate int RandomState instance or None default0 Determines random number
generation for dataset shuffling Pass an int for reproducible output across multiple function
calls See Glossary
downloadifmissing optional True by default If False raise a IOError if the data is not
locally available instead of trying to download the data from the source site

Returns
An object with the following attributes
data numpy array of shape 400 4096 Each row corresponds to a ravelled face image of
original size 64 x 64 pixels
images numpy array of shape 400 64 64 Each row is a face image corresponding to one of
the 40 subjects of the dataset
target numpy array of shape 400 Labels associated to each face image Those labels are
ranging from 039 and correspond to the Subject IDs
DESCR string Description of the modified Olivetti Faces Dataset
Examples using sklearndatasetsfetcholivettifaces
•Face completion with a multioutput estimators
•Online learning of a dictionary of parts of faces
•Faces dataset decompositions
•Pixel importances with a parallel forest of trees
sklearndatasets fetchopenml
sklearndatasets fetchopenml nameNone version’active’ dataidNone datahomeNone
targetcolumn’defaulttarget’ cacheTrue returnXyFalse
Fetch dataset from openml by name or dataset id
Datasets are uniquely identified by either an integer ID or by a combination of name and version ie there
might be multiple versions of the ‘iris’ dataset Please give either name or dataid not both In case a name is
given a version can also be provided
Read more in the User Guide
Note EXPERIMENTAL
The API is experimental particularly the return value structure and might have small backwardincompatible
changes in future releases
Parameters
name str or None String identifier of the dataset Note that OpenML can have multiple
datasets with the same name
version integer or ‘active’ default’active’ Version of the dataset Can only be provided if
alsoname is given If ‘active’ the oldest version that’s still active is used Since there
may be more than one active version of a dataset and those versions may fundamentally be
different from one another setting an exact version is highly recommended
dataid int or None OpenML ID of the dataset The most specific way of retrieving a dataset
If dataid is not given name and potential version are used to obtain a dataset
datahome string or None default None Specify another download and cache folder for the
data sets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders

targetcolumn string list or None default ‘defaulttarget’ Specify the column name in the
data to use as target If ‘defaulttarget’ the standard target column a stored on the server is
used IfNone all columns are returned as data and the target is None If list of strings all
columns with these names are returned as multitarget Note not all scikitlearn classifiers
can handle all types of multioutput combinations
cache boolean defaultTrue Whether to cache downloaded datasets using joblib
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget objects
Returns
data Bunch Dictionarylike object with attributes
data nparray or scipysparsecsrmatrix of floats The feature matrix Categorical features
are encoded as ordinals
target nparray The regression target or classification labels if applicable Dtype is float
if numeric and object if categorical
DESCR str The full description of the dataset
featurenames list The names of the dataset columns
categories dict Maps each categorical feature name to a list of values such that the value
encoded as i is ith in the list
details dict More metadata from OpenML
data target tuple ifreturnXy is True
Note EXPERIMENTAL
This interface is experimental and subsequent releases may change attributes without notice
although there should only be minor changes to data andtarget
Missing values in the ‘data’ are represented as NaN’s Missing values in ‘target’ are repre
sented as NaN’s numerical target or None categorical target
Examples using sklearndatasetsfetchopenml
•Gaussian process regression GPR on Mauna Loa CO2 data
•MNIST classfification using multinomial logistic L1
•Early stopping of Stochastic Gradient Descent
•Classifier Chain
•Visualization of MLP weights on MNIST
sklearndatasets fetchrcv1
sklearndatasets fetchrcv1 datahomeNone subset’all’ downloadifmissingTrue ran
domstateNone shuffleFalse returnXyFalse
Load the RCV1 multilabel dataset classification
Download it if necessary

scikitlearn user guide Release 0213
Version RCV1v2 vectors full sets topics multilabels
Classes 103
Samples total 804414
Dimensionality 47236
Features real between 0 and 1
Read more in the User Guide
New in version 017
Parameters
datahome string optional Specify another download and cache folder for the datasets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders
subset string ‘train’ ‘test’ or ‘all’ default’all’ Select the dataset to load ‘train’ for the training set 23149 samples ‘test’ for the test set 781265 samples ‘all’ for both with the training samples first if shuffle is False This follows the official LYRL2004 chronological split
downloadifmissing boolean defaultTrue If False raise a IOError if the data is not locally available instead of trying to download the data from the source site
randomstate int RandomState instance or None default Determines random number gen eration for dataset shuffling Pass an int for reproducible output across multiple function calls See Glossary
shuffle bool defaultFalse Whether to shuffle dataset
returnXy boolean defaultFalse If True returns datasetdata dataset
target instead of a Bunch object See below for more information about the dataset data anddatasettarget object
New in version 020
Returns
dataset dictlike object with the following attributes
datasetdata scipy csr array dtype npfloat64 shape 804414 47236 The array has 016 of non zero values
datasettarget scipy csr array dtype npuint8 shape 804414 103 Each sample has a value of 1 in its categories and 0 in others The array has 315 of non zero values
datasetsampleid numpy array dtype npuint32 shape 804414 Identification number of each sample as ordered in datasetdata
datasettargetnames numpy array dtype object length 103 Names of each target RCV1 topics as ordered in datasettarget
datasetDESCR string Description of the RCV1 dataset
data target tuple ifreturnXy is True New in version 020
sklearndatasets fetchspeciesdistributions
sklearndatasets fetchspeciesdistributions datahomeNone down loadifmissingTrue
Loader for species distribution dataset from Phillips et al 2006

scikitlearn user guide Release 0213
Read more in the User Guide
Parameters
datahome optional default None Specify another download and cache folder for the
datasets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders
downloadifmissing optional True by default If False raise a IOError if the data is not
locally available instead of trying to download the data from the source site
Returns
The data is returned as a Bunch object with the following attributes
coverages array shape 14 1592 1212 These represent the 14 features measured at each
point of the map grid The latitudelongitude values for the grid are discussed below Miss
ing data is represented by the value 9999
train record array shape 1624 The training points for the data Each point has three fields
• train‘species’ is the species name
• train‘dd long’ is the longitude in degrees
• train‘dd lat’ is the latitude in degrees
test record array shape 620 The test points for the data Same format as the training data
Nx Ny integers The number of longitudes x and latitudes y in the grid
xleftlowercorner yleftlowercorner floats The xy position of the lowerleft corner
in degrees
gridsize float The spacing between points of the grid in degrees
Notes
This dataset represents the geographic distribution of species The dataset is provided by Phillips et al 2006
The two species are
• “Bradypus variegatus” the Brownthroated Sloth
• “Microryzomys minutus” also known as the Forest Small Rice Rat a rodent that lives in Peru Colombia
Ecuador Peru and Venezuela
• For an example of using this dataset with scikitlearn see exam
plesapplicationsplotspeciesdistributionmodelingpy

•Species distribution modeling
•Kernel Density Estimate of Species Distributions

sklearndatasets getdatahome
sklearndatasets getdatahome datahomeNone
Return the path of the scikitlearn data dir
This folder is used by some large dataset loaders to avoid downloading the data several times
By default the data dir is set to a folder named ‘scikitlearndata’ in the user home folder
Alternatively it can be set by the ‘SCIKITLEARNDATA’ environment variable or programmatically by giving
an explicit folder path The ‘’ symbol is expanded to the user home folder
If the folder does not already exist it is automatically created
Parameters
datahome str None The path to scikitlearn data dir
Examples using sklearndatasetsgetdatahome
•Outofcore classification of text documents
sklearndatasets loadboston
sklearndatasets loadboston returnXyFalse
Load and return the boston houseprices dataset regression
Samples total 506
Dimensionality 13
Features real positive
Targets real 5 50
Read more in the User Guide
Parameters
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget object
New in version 018
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘target’ the regression targets ‘DESCR’ the full description of the dataset and ‘filename’
the physical location of boston csv dataset added in version 020
data target tuple ifreturnXy is True New in version 018
Notes
Changed in version 020 Fixed a wrong data point at 445 0

Examples
```
 from sklearndatasets import loadboston
boston  loadboston
printbostondatashape
```
506 13
Examples using sklearndatasetsloadboston
•Outlier detection on a real data set
•Model Complexity Influence
•Effect of transforming the targets in regression model
•Plot individual and voting regression predictions
•Gradient Boosting regression
•Feature selection using SelectFromModel and LassoCV
•Imputing missing values before building an estimator
•Plotting CrossValidated Predictions
sklearndatasets loadbreastcancer
sklearndatasets loadbreastcancer returnXyFalse
Load and return the breast cancer wisconsin dataset classification
The breast cancer dataset is a classic and very easy binary classification dataset
Classes 2
Samples per class 212M357B
Samples total 569
Dimensionality 30
Features real positive
Read more in the User Guide
Parameters
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget object
New in version 018
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘target’ the classification labels ‘targetnames’ the meaning of the labels ‘featurenames’
the meaning of the features and ‘DESCR’ the full description of the dataset ‘filename’ the
physical location of breast cancer csv dataset added in version 020
data target tuple ifreturnXy is True New in version 018
The copy of UCI ML Breast Cancer Wisconsin Diagnostic dataset is
downloaded from

scikitlearn user guide Release 0213

sklearndatasets loaddigits
sklearndatasets loaddigits nclass10 returnXyFalse
Load and return the digits dataset classification
Each datapoint is a 8x8 image of a digit
Classes 10
Samples per class 180
Samples total 1797
Dimensionality 64
Features integers 016
Read more in the User Guide
Parameters
nclass integer between 0 and 10 optional default10 The number of classes to return
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget object
New in version 018
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘images’ the images corresponding to each sample ‘target’ the classification labels for
each sample ‘targetnames’ the meaning of the labels and ‘DESCR’ the full description
of the dataset
data target tuple ifreturnXy is True New in version 018
This is a copy of the test set of the UCI ML handwritten digits datasets
httpsarchiveicsuciedumldatasetsOpticalRecognitionofHandwrittenDigits
Examples
To load the data and visualize the images
```
 from sklearndatasets import loaddigits
digits  loaddigits
printdigitsdatashape
1797 64
 import matplotlibpyplot as plt
pltgray
pltmatshowdigitsimages0
pltshow
```
Examples using sklearndatasetsloaddigits
•The JohnsonLindenstrauss bound for embedding with random projections
•Explicit feature map approximation for RBF kernels
•Recognizing handwritten digits

•Feature agglomeration
•Various Agglomerative Clustering on a 2D embedding of digits
•A demo of KMeans clustering on the handwritten digits data
•Pipelining chaining a PCA and a logistic regression
•Selecting dimensionality reduction with Pipeline and GridSearchCV
•The Digit Dataset
•Early stopping of Gradient Boosting
•Digits Classification Exercise
•Crossvalidation on Digits Dataset Exercise
•Recursive feature elimination
•Comparing various online solvers
•L1 Penalty and Sparsity in Logistic Regression
•Manifold learning on handwritten digits Locally Linear Embedding Isomap
•Plotting Validation Curves
•Parameter estimation using grid search with crossvalidation
•Comparing randomized search and grid search for hyperparameter estimation
•Balance model complexity and crossvalidated score
•Plotting Learning Curves
•Kernel Density Estimation
•Dimensionality Reduction with Neighborhood Components Analysis
•Restricted Boltzmann Machine features for digit classification
•Compare Stochastic learning strategies for MLPClassifier
•Label Propagation digits Demonstrating performance
•Label Propagation digits active learning
sklearndatasets loadfiles
sklearndatasets loadfiles containerpath descriptionNone categoriesNone
loadcontentTrue shuffleTrue encodingNone de
codeerror'strict' randomstate0
Load text files with categories as subfolder names
Individual samples are assumed to be files stored a two levels folder structure such as the following
containerfolder
category1folder file1txt file2txt file42txt
category2folder file43txt file44txt
The folder names are used as supervised signal label names The individual file names are not important
This function does not try to extract features into a numpy array or scipy sparse matrix In addition if
loadcontent is false it does not try to load the files in memory

scikitlearn user guide Release 0213
To use text files in a scikitlearn classification or clustering algorithm you will need to use the sklearn featureextractiontext module to build a feature extraction transformer that suits your problem
If you set loadcontentTrue you should also specify the encoding of the text using the ‘encoding’ parameter For many modern text files ‘utf8’ will be the correct encoding If you leave encoding equal to None then the content will be made of bytes instead of Unicode and you will not be able to use most functions in sklearn featureextractiontext
Similar feature extractors should be built for other kind of unstructured data input such as images audio video

Read more in the User Guide
Parameters
containerpath string or unicode Path to the main folder holding one subfolder per category
description string or unicode optional defaultNone A paragraph describing the character istic of the dataset its source reference etc
categories A collection of strings or None optional defaultNone If None default load all the categories If not None list of category names to load other categories ignored
loadcontent boolean optional defaultTrue Whether to load or not the content of the dif ferent files If true a ‘data’ attribute containing the text information is present in the data structure returned If not a filenames attribute gives the path to the files
shuffle bool optional defaultTrue Whether or not to shuffle the data might be important for models that make the assumption that the samples are independent and identically dis tributed iid such as stochastic gradient descent
encoding string or None default is None If None do not try to decode the content of the files eg for images or other nontext content If not None encoding to use to decode text files to Unicode if loadcontent is True
decodeerror ‘strict’ ‘ignore’ ‘replace’ optional Instruction on what to do if a byte se quence is given to analyze that contains characters not of the given encoding Passed as keyword argument ‘errors’ to bytesdecode
randomstate int RandomState instance or None default0 Determines random number generation for dataset shuffling Pass an int for reproducible output across multiple function calls See Glossary
Returns
data Bunch Dictionarylike object the interesting attributes are either data the raw text data to learn or ‘filenames’ the files holding it ‘target’ the classification labels integer index ‘targetnames’ the meaning of the labels and ‘DESCR’ the full description of the dataset
sklearndatasets loadiris
sklearndatasets loadiris returnXyFalse
Load and return the iris dataset classification
The iris dataset is a classic and very easy multiclass classification dataset

object See below for more information about the data andtarget object
New in version 018
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘target’ the classification labels ‘targetnames’ the meaning of the labels ‘featurenames’
the meaning of the features ‘DESCR’ the full description of the dataset ‘filename’ the
physical location of iris csv dataset added in version 020
data target tuple ifreturnXy is True New in version 018
Notes
Changed in version 020 Fixed two wrong data points according to Fisher’s paper The new version is the same
as in R but not as in the UCI Machine Learning Repository
Examples
Let’s say you are interested in the samples 10 25 and 50 and want to know their class name
 from sklearndatasets import loadiris
data loadiris
datatarget10 25 50
array0 0 1
listdatatargetnames
setosa versicolor virginica
Examples using sklearndatasetsloadiris
•Plot classification probability
•Kmeans Clustering
•Concatenating multiple feature extraction methods
•The Iris Dataset
•PCA example with Iris Dataset
•Incremental PCA
•Comparison of LDA and PCA 2D projection of Iris dataset
•Plot the decision boundaries of a VotingClassifier
68sklearndatasets Datasets 1597

•Early stopping of Gradient Boosting
•Plot the decision surfaces of ensembles of trees on the iris dataset
•SVM Exercise
•Test with permutations the significance of a classification score
•Univariate Feature Selection
•Gaussian process classification GPC on iris dataset
•Regularization path of L1 Logistic Regression
•Logistic Regression 3class Classifier
•Plot multiclass SGD on the iris dataset
•GMM covariances
•Receiver Operating Characteristic ROC with cross validation
•Nested versus nonnested crossvalidation
•Confusion matrix
•Receiver Operating Characteristic ROC
•PrecisionRecall
•Nearest Neighbors Classification
•Nearest Centroid Classification
•Comparing Nearest Neighbors with and without Neighborhood Components Analysis
•Compare Stochastic learning strategies for MLPClassifier
•Decision boundary of label propagation versus SVM on the Iris dataset
•SVM with custom kernel
•SVMAnova SVM with univariate feature selection
•Plot different SVM classifiers in the iris dataset
•RBF SVM parameters
•Plot the decision surface of a decision tree on the iris dataset
•Understanding the decision tree structure
sklearndatasets loadlinnerud
sklearndatasets loadlinnerud returnXyFalse
Load and return the linnerud dataset multivariate regression
Samples total 20
Dimensionality 3 for both data and target
Features integer
Targets integer
Read more in the User Guide
Parameters

scikitlearn user guide Release 0213
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget object
New in version 018
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ and ‘target’ the two
multivariate datasets with ‘data’ corresponding to the exercise and ‘target’ corresponding
to the physiological measurements as well as ‘featurenames’ and ‘targetnames’ In addi
tion you will also have access to ‘datafilename’ the physical location of linnerud data csv
dataset and ‘targetfilename’ the physical location of linnerud targets csv datataset added
in version020
data target tuple ifreturnXy is True New in version 018
sklearndatasets loadsampleimage
sklearndatasets loadsampleimage imagename
Load the numpy array of a single sample image
Read more in the User Guide
Parameters
imagename chinajpg flowerjpg The name of the sample image loaded
Returns
img 3D array The image as a numpy array height x width x color
Examples
 from sklearndatasets import loadsampleimage
china loadsampleimagechinajpg
chinadtype
dtypeuint8
chinashape
427 640 3
flower loadsampleimageflowerjpg
flowerdtype
dtypeuint8
flowershape
427 640 3
Examples using sklearndatasetsloadsampleimage
•Color Quantization using KMeans
sklearndatasets loadsampleimages
sklearndatasets loadsampleimages
Load sample images for image manipulation
Loads both china andflower
68sklearndatasets Datasets 1599

scikitlearn user guide Release 0213
Read more in the User Guide
Returns
data Bunch Dictionarylike object with the following attributes ‘images’ the two sample images ‘filenames’ the file names for the images and ‘DESCR’ the full description of the dataset
Examples
To load the data and visualize the images
from sklearndatasets import loadsampleimages
dataset loadsampleimages

firstimgdatadtype
dtypeuint8
sklearndatasets loadsvmlightfile
sklearndatasets loadsvmlightfile fnfeaturesNone dtypeclass ‘numpyfloat64’ multilabelFalse zerobased’auto’ queryidFalse
offset0 length1
Load datasets in the svmlight libsvm format into sparse CSR matrix
This format is a textbased format with one sample per line It does not store zero valued features hence is suitable for sparse dataset
The first element of each line can be used to store a target variable to predict
This format is used as the default format for both svmlight and the libsvm command line programs
Parsing a text based source can be expensive When working on repeatedly on the same dataset it is recommended to wrap this loader with joblibMemorycache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls
In case the file contains a pairwise preference constraint known as “qid” in the svmlight format these are ignored unless the queryid parameter is set to True These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions as is the case in some learning to rank problems so that only pairs with the same queryid value are considered
This implementation is written in Cython and is reasonably fast However a faster APIcompatible loader is also available at
httpsgithubcommblondelsvmlightloader
Parameters
fstr filelike int Path to a file to load If a path ends in “gz” or “bz2” it will be uncompressed on the fly If an integer is passed it is assumed to be a file descriptor A filelike or file descriptor will not be closed by this function A filelike object must be opened in binary mode

nfeatures int or None The number of features to use If None it will be inferred This argument is useful to load several files that are subsets of a bigger sliced dataset each subset might not have examples of every feature hence the inferred shape might vary from one slice to another nfeatures is only required if offset orlength are passed a non default value
dtype numpy data type default npfloat64 Data type of dataset to be loaded This will be the data type of the output numpy arrays Xandy
multilabel boolean optional default False Samples may have several labels each see https wwwcsientuedutwcjlinlibsvmtoolsdatasetsmultilabelhtml
zerobased boolean or “auto” optional default “auto” Whether column indices in f are zero based True or onebased False If column indices are onebased they are transformed to zerobased to match PythonNumPy conventions If set to “auto” a heuristic check is applied to determine this from the file contents Both kinds of files occur “in the wild” but they are unfortunately not selfidentifying Using “auto” or True should always be safe when nooffset orlength is passed If offset orlength are passed the “auto” mode falls back tozerobasedTrue to avoid having the heuristic check yield inconsistent results on different segments of the file
queryid boolean default False If True will return the queryid array for each file
offset integer optional default 0 Ignore the offset first bytes by seeking forward then dis carding the following bytes up until the next new line character
length integer optional default 1 If strictly positive stop reading any new line of data once the position in the file has reached the offset length bytes threshold
Returns
Xscipysparse matrix of shape nsamples nfeatures
yndarray of shape nsamples or in the multilabel a list of tuples of length nsamples
queryid array of shape nsamples queryid for each sample Only returned when queryid is set to True
See also
loadsvmlightfiles similar function for loading multiple files in this format enforcing the same num ber of featurescolumns on all of them
Examples
To use joblibMemory to cache the svmlight file
```
from joblib import Memory
from datasets import loadsvmlightfile
mem  Memorymycache
memcache
defgetdata
data  loadsvmlightfilemysvmlightfile
returndata0 data1
X y  getdata
```

sklearndatasets loadsvmlightfiles
sklearndatasets loadsvmlightfiles files nfeaturesNone dtypeclass
‘numpyfloat64’ multilabelFalse
zerobased’auto’ queryidFalse offset0 length
1
Load dataset from multiple files in SVMlight format
This function is equivalent to mapping loadsvmlightfile over a list of files except that the results are concate
nated into a single flat list and the samples vectors are constrained to all have the same number of features
In case the file contains a pairwise preference constraint known as “qid” in the svmlight format these are
ignored unless the queryid parameter is set to True These pairwise preference constraints can be used to
constraint the combination of samples when using pairwise loss functions as is the case in some learning to
rank problems so that only pairs with the same queryid value are considered
Parameters
files iterable over str filelike int Paths of files to load If a path ends in “gz” or “bz2” it
will be uncompressed on the fly If an integer is passed it is assumed to be a file descriptor
Filelikes and file descriptors will not be closed by this function Filelike objects must be
opened in binary mode
nfeatures int or None The number of features to use If None it will be inferred from the
maximum column index occurring in any of the files
This can be set to a higher value than the actual number of features in any of the input files
but setting it to a lower value will cause an exception to be raised
dtype numpy data type default npfloat64 Data type of dataset to be loaded This will be the
data type of the output numpy arrays Xandy
multilabel boolean optional Samples may have several labels each see httpswwwcsientu
edutwcjlinlibsvmtoolsdatasetsmultilabelhtml
zerobased boolean or “auto” optional Whether column indices in f are zerobased True or
onebased False If column indices are onebased they are transformed to zerobased to
match PythonNumPy conventions If set to “auto” a heuristic check is applied to determine
this from the file contents Both kinds of files occur “in the wild” but they are unfortunately
not selfidentifying Using “auto” or True should always be safe when no offset or length
is passed If offset or length are passed the “auto” mode falls back to zerobasedTrue to
avoid having the heuristic check yield inconsistent results on different segments of the file
queryid boolean defaults to False If True will return the queryid array for each file
offset integer optional default 0 Ignore the offset first bytes by seeking forward then dis
carding the following bytes up until the next new line character
length integer optional default 1 If strictly positive stop reading any new line of data once
the position in the file has reached the offset length bytes threshold
Returns
X1 y1 Xn yn
where each Xi yi pair is the result from loadsvmlightfilefilesi
If queryid is set to True this will return instead X1 y1 q1
  Xn yn qn where Xi yi qi is the result from
loadsvmlightfilefilesi
See also

loadsvmlightfile
Notes
When fitting a model to a matrix Xtrain and evaluating it against a matrix Xtest it is essential that Xtrain
and Xtest have the same number of features Xtrainshape1 Xtestshape1 This may not be the case
if you load the files individually with loadsvmlightfile
sklearndatasets loadwine
sklearndatasets loadwine returnXyFalse
Load and return the wine dataset classification
New in version 018
The wine dataset is a classic and very easy multiclass classification dataset
Classes 3
Samples per class 597148
Samples total 178
Dimensionality 13
Features real positive
Read more in the User Guide
Parameters
returnXy boolean defaultFalse If True returns data target instead of a Bunch
object See below for more information about the data andtarget object
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘target’ the classification labels ‘targetnames’ the meaning of the labels ‘featurenames’
the meaning of the features and ‘DESCR’ the full description of the dataset
data target tuple ifreturnXy is True
The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit
standard format from
httpsarchiveicsuciedumlmachinelearningdatabaseswinewinedata
Examples
Let’s say you are interested in the samples 10 80 and 140 and want to know their class name
```
 from sklearndatasets import loadwine
data  loadwine
datatarget10 80 140
array0 1 2
listdatatargetnames
class0 class1 class2
```

sklearndatasets makeclassification
sklearndatasets makeclassification nsamples100 nfeatures20 ninformative2
nredundant2 nrepeated0 nclasses2
nclustersperclass2 weightsNone flipy001
classsep10 hypercubeTrue shift00 scale10
shuffleTrue randomstateNone
Generate a random nclass classification problem

This initially creates clusters of points normally distributed std1 about vertices of an ninformative
dimensional hypercube with sides of length 2classsep and assigns an equal number of clusters to each
class It introduces interdependence between these features and adds various types of further noise to the data
Without shuffling Xhorizontally stacks features in the following order the primary ninformative fea
tures followed by nredundant linear combinations of the informative features followed by nrepeated
duplicates drawn randomly with replacement from the informative and redundant features The remaining fea
tures are filled with random noise Thus without shuffling all useful features are contained in the columns
X ninformative nredundant nrepeated
Read more in the User Guide
Parameters
nsamples int optional default100 The number of samples
nfeatures int optional default20 The total number of fea
tures These comprise ninformative informative features
nredundant redundant features nrepeated duplicated features and
nfeaturesninformativenredundantnrepeated useless features
drawn at random
ninformative int optional default2 The number of informative features Each class is
composed of a number of gaussian clusters each located around the vertices of a hypercube
in a subspace of dimension ninformative For each cluster informative features are
drawn independently from N0 1 and then randomly linearly combined within each cluster
in order to add covariance The clusters are then placed on the vertices of the hypercube
nredundant int optional default2 The number of redundant features These features are
generated as random linear combinations of the informative features
nrepeated int optional default0 The number of duplicated features drawn randomly
from the informative and the redundant features
nclasses int optional default2 The number of classes or labels of the classification prob
lem
nclustersperclass int optional default2 The number of clusters per class
weights list of floats or None defaultNone The proportions of samples assigned to each
class If None then classes are balanced Note that if lenweights nclasses
 1 then the last class weight is automatically inferred More than nsamples samples
may be returned if the sum of weights exceeds 1
flipy float optional default001 The fraction of samples whose class are randomly ex
changed Larger values introduce noise in the labels and make the classification task harder
classsep float optional default10 The factor multiplying the hypercube size Larger val
ues spread out the clustersclasses and make the classification task easier
hypercube boolean optional defaultTrue If True the clusters are put on the vertices of a
hypercube If False the clusters are put on the vertices of a random polytope
shift float array of shape nfeatures or None optional default00 Shift features by the
specified value If None then features are shifted by a random value drawn in classsep
classsep
scale float array of shape nfeatures or None optional default10 Multiply features by
the specified value If None then features are scaled by a random value drawn in 1 100
Note that scaling happens after shifting
shuffle boolean optional defaultTrue Shuffle the samples and the features

randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
Xarray of shape nsamples nfeatures The generated samples
yarray of shape nsamples The integer labels for class membership of each sample
See also
makeblobs simplified variant

sklearndatasets makegaussianquantiles
sklearndatasets makegaussianquantiles meanNone cov10 nsamples100
nfeatures2 nclasses3 shuffleTrue
randomstateNone
Generate isotropic Gaussian and label samples by quantile
This classification dataset is constructed by taking a multidimensional standard normal distribution and defining
classes separated by nested concentric multidimensional spheres such that roughly equal numbers of samples
are in each class quantiles of the 2distribution
Read more in the User Guide
Parameters
mean array of shape nfeatures optional defaultNone The mean of the multi
dimensional normal distribution If None then use the origin 0 0
cov float optional default1 The covariance matrix will be this value times the unit matrix
This dataset only produces symmetric normal distributions
nsamples int optional default100 The total number of points equally divided among
classes
nfeatures int optional default2 The number of features for each sample
nclasses int optional default3 The number of classes
shuffle boolean optional defaultTrue Shuffle the samples
randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
Xarray of shape nsamples nfeatures The generated samples
yarray of shape nsamples The integer labels for quantile membership of each sample
Notes
The dataset is from Zhu et al 1

sklearndatasets makelowrankmatrix
sklearndatasets makelowrankmatrix nsamples100 nfeatures100 effectiverank10
tailstrength05 randomstateNone
Generate a mostly low rank matrix with bellshaped singular values
Most of the variance can be explained by a bellshaped curve of width effectiverank the low rank part of the
singular values profile is
1 tailstrength exp10 i effectiverank 2
The remaining singular values’ tail is fat decreasing as
tailstrength exp01 i effectiverank

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components singular vectors
This kind of singular profiles is often seen in practice for instance
• gray level pictures of faces
• TFIDF vectors of text documents crawled from the web
Read more in the User Guide
Parameters
nsamples int optional default100 The number of samples
nfeatures int optional default100 The number of features
effectiverank int optional default10 The approximate number of singular vectors re quired to explain most of the data by linear combinations
tailstrength float between 00 and 10 optional default05 The relative importance of the fat noisy tail of the singular values profile
randomstate int RandomState instance or None default Determines random number gen eration for dataset creation Pass an int for reproducible output across multiple function calls See Glossary
Returns
Xarray of shape nsamples nfeatures The matrix
sklearndatasets makemoons
sklearndatasets makemoons nsamples100 shuffleTrue noiseNone randomstateNone
Make two interleaving half circles
A simple toy dataset to visualize clustering and classification algorithms Read more in the User Guide

shuffle bool optional defaultTrue Whether to shuffle the samples
noise double or None defaultNone Standard deviation of Gaussian noise added to the data
randomstate int RandomState instance or None default Determines random number gen eration for dataset shuffling and noise Pass an int for reproducible output across multiple function calls See Glossary
Returns
Xarray of shape nsamples 2 The generated samples
yarray of shape nsamples The integer labels 0 or 1 for class membership of each sample
Examples using sklearndatasetsmakemoons
•Comparing anomaly detection algorithms for outlier detection on toy datasets
•Classifier comparison
•Comparing different hierarchical linkage methods on toy datasets

•Comparing different clustering algorithms on toy datasets
•Varying regularization in Multilayer Perceptron
•Compare Stochastic learning strategies for MLPClassifier
•Feature discretization
sklearndatasets makemultilabelclassification
sklearndatasets makemultilabelclassification nsamples100 nfeatures20
nclasses5 nlabels2 length50
allowunlabeledTrue sparseFalse
returnindicator'dense' re
turndistributionsFalse ran
domstateNone
Generate a random multilabel classification problem
For each sample the generative process is
• pick the number of labels n Poissonnlabels
• n times choose a class c c Multinomialtheta
• pick the document length k Poissonlength
• k times choose a word w Multinomialthetac
In the above process rejection sampling is used to make sure that n is never zero or more than nclasses
and that the document length is never zero Likewise we reject classes which have already been chosen
Read more in the User Guide
Parameters
nsamples int optional default100 The number of samples
nfeatures int optional default20 The total number of features
nclasses int optional default5 The number of classes of the classification problem
nlabels int optional default2 The average number of labels per instance More precisely
the number of labels per sample is drawn from a Poisson distribution with nlabels as its
expected value but samples are bounded using rejection sampling by nclasses and
must be nonzero if allowunlabeled is False
length int optional default50 The sum of the features number of words if documents is
drawn from a Poisson distribution with this expected value
allowunlabeled bool optional defaultTrue If True some instances might not belong to
any class
sparse bool optional defaultFalse If True return a sparse feature matrix
New in version 017 parameter to allow sparse output
returnindicator 'dense' default 'sparse' False If dense returnYin the dense binary
indicator format If sparse returnYin the sparse binary indicator format False
returns a list of lists of labels
returndistributions bool optional defaultFalse If True return the prior class probability
and conditional probabilities of features given classes from which the data was drawn

randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
Xarray of shape nsamples nfeatures The generated samples
Yarray or sparse CSR matrix of shape nsamples nclasses The label sets
pc array shape nclasses The probability of each class being drawn Only returned if
returndistributionsTrue
pwc array shape nfeatures nclasses The probability of each feature being drawn given
each class Only returned if returndistributionsTrue
Examples using sklearndatasetsmakemultilabelclassification
•Multilabel classification
•Plot randomly generated multilabel dataset
sklearndatasets makeregression
sklearndatasets makeregression nsamples100 nfeatures100 ninformative10
ntargets1 bias00 effectiverankNone
tailstrength05 noise00 shuffleTrue coefFalse
randomstateNone
Generate a random regression problem
The input set can either be well conditioned by default or have a low rankfat tail singular profile See
makelowrankmatrix for more details
The output is generated by applying a potentially biased random linear regression model with
ninformative nonzero regressors to the previously generated input and some gaussian centered noise with
some adjustable scale
Read more in the User Guide
Parameters
nsamples int optional default100 The number of samples
nfeatures int optional default100 The number of features
ninformative int optional default10 The number of informative features ie the number
of features used to build the linear model used to generate the output
ntargets int optional default1 The number of regression targets ie the dimension of the
y output vector associated with a sample By default the output is a scalar
bias float optional default00 The bias term in the underlying linear model
effectiverank int or None optional defaultNone
if not None The approximate number of singular vectors required to explain most of the
input data by linear combinations Using this kind of singular spectrum in the input allows
the generator to reproduce the correlations often observed in practice
if None The input set is well conditioned centered and gaussian with unit variance

tailstrength float between 00 and 10 optional default05 The relative importance of the fat noisy tail of the singular values profile if effectiverank is not None
noise float optional default00 The standard deviation of the gaussian noise applied to the output
shuffle boolean optional defaultTrue Shuffle the samples and the features
coef boolean optional defaultFalse If True the coefficients of the underlying linear model are returned
randomstate int RandomState instance or None default Determines random number gen eration for dataset creation Pass an int for reproducible output across multiple function calls See Glossary
Returns
Xarray of shape nsamples nfeatures The input samples
yarray of shape nsamples or nsamples ntargets The output values
coef array of shape nfeatures or nfeatures ntargets optional The coefficient of the underlying linear model It is returned only if coef is True
Examples using sklearndatasetsmakeregression
•Prediction Latency
•Effect of transforming the targets in regression model
•Plot Ridge coefficients as a function of the L2 regularization
•Robust linear model estimation using RANSAC
•Lasso on dense and sparse data
•HuberRegressor vs Ridge on dataset with strong outliers
sklearndatasets makescurve
sklearndatasets makescurve nsamples100 noise00 randomstateNone
Generate an S curve dataset
Read more in the User Guide
Parameters
nsamples int optional default100 The number of sample points on the S curve
noise float optional default00 The standard deviation of the gaussian noise
randomstate int RandomState instance or None default Determines random number gen eration for dataset creation Pass an int for reproducible output across multiple function calls See Glossary
Returns
Xarray of shape nsamples 3 The points
tarray of shape nsamples The univariate position of the sample according to the main dimension of the points in the manifold

Examples using sklearndatasetsmakescurve
•tSNE The effect of various perplexity values on the shape
•Comparison of Manifold Learning methods
sklearndatasets makesparsecodedsignal
sklearndatasets makesparsecodedsignal nsamples ncomponents nfeatures
nnonzerocoefs randomstateNone
Generate a signal as a sparse combination of dictionary elements
Returns a matrix Y DX such as D is nfeatures ncomponents X is ncomponents nsamples and each
column of X has exactly nnonzerocoefs nonzero elements
Read more in the User Guide
Parameters
nsamples int number of samples to generate
ncomponents int number of components in the dictionary
nfeatures int number of features of the dataset to generate
nnonzerocoefs int number of active nonzero coefficients in each sample
randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
data array of shape nfeatures nsamples The encoded signal Y
dictionary array of shape nfeatures ncomponents The dictionary with normalized com
ponents D
code array of shape ncomponents nsamples The sparse code such that each column of
this matrix has exactly nnonzerocoefs nonzero items X
Examples using sklearndatasetsmakesparsecodedsignal
•Orthogonal Matching Pursuit
sklearndatasets makesparsespdmatrix
sklearndatasets makesparsespdmatrix dim1 alpha095 normdiagFalse
smallestcoef01 largestcoef09 ran
domstateNone
Generate a sparse symmetric definite positive matrix
Read more in the User Guide
Parameters
dim integer optional default1 The size of the random matrix to generate
alpha float between 0 and 1 optional default095 The probability that a coefficient is zero
see notes Larger values enforce more sparsity

normdiag boolean optional defaultFalse Whether to normalize the output matrix to make
the leading diagonal elements all 1
smallestcoef float between 0 and 1 optional default01 The value of the smallest coeffi
cient
largestcoef float between 0 and 1 optional default09 The value of the largest coefficient
randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
prec sparse matrix of shape dim dim The generated matrix
See also
makespdmatrix
Notes
The sparsity is actually imposed on the cholesky factor of the matrix Thus alpha does not translate directly into
the filling fraction of the matrix itself
Examples using sklearndatasetsmakesparsespdmatrix
•Sparse inverse covariance estimation
sklearndatasets makesparseuncorrelated
sklearndatasets makesparseuncorrelated nsamples100 nfeatures10 ran
domstateNone
Generate a random regression problem with sparse uncorrelated design
This dataset is described in Celeux et al 1 as
X N0 1
yX X 0 2 X 1 2 X 2 15 X 3
Only the first 4 features are informative The remaining features are useless
Read more in the User Guide
Parameters
nsamples int optional default100 The number of samples
nfeatures int optional default10 The number of features
randomstate int RandomState instance or None default Determines random number gen
eration for dataset creation Pass an int for reproducible output across multiple function
calls See Glossary
Returns
Xarray of shape nsamples nfeatures The input samples
yarray of shape nsamples The output values

ber of samples and nfeatures is the number of features
yIgnored
Returns
self object Returns the object itself

fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Encode the data as a sparse combination of the dictionary atoms
Coding method is determined by the object parameter transformalgorithm
Parameters
Xarray of shape nsamples nfeatures Test data to be transformed must have the same
number of features as the data used to train the model
Returns

classsklearndecomposition FactorAnalysis ncomponentsNone tol001 copyTrue
maxiter1000 noisevarianceinitNone
svdmethod’randomized’ iteratedpower3
randomstate0
Factor Analysis FA
A simple linear generative model with Gaussian latent variables
The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and
added Gaussian noise Without loss of generality the factors are distributed according to a Gaussian with zero
mean and unit covariance The noise is also zero mean and has an arbitrary diagonal covariance matrix

If we would restrict the model further by assuming that the Gaussian noise is even isotropic all diagonal entries are the same we would obtain PPCA
FactorAnalysis performs a maximum likelihood estimate of the socalled loading matrix the transformation of the latent variables to the observed ones using expectationmaximization EM
Read more in the User Guide
Parameters
ncomponents int None Dimensionality of latent space the number of components of Xthat are obtained after transform If None ncomponents is set to the number of features
tolfloat Stopping tolerance for EM algorithm
copy bool Whether to make a copy of X If False the input X gets overwritten during fitting
maxiter int Maximum number of iterations
noisevarianceinit None array shapenfeatures The initial guess of the noise variance for each feature If None it defaults to nponesnfeatures
svdmethod ‘lapack’ ‘randomized’ Which SVD method to use If ‘lapack’ use standard SVD from scipylinalg if ‘randomized’ use fast randomizedsvd function Defaults to ‘randomized’ For most applications ‘randomized’ will be sufficiently precise while pro viding significant speed gains Accuracy can also be improved by setting higher values for iteratedpower If this is not sufficient for maximum precision you should choose ‘lapack’
iteratedpower int optional Number of iterations for the power method 3 by default Only used ifsvdmethod equals ‘randomized’
randomstate int RandomState instance or None optional default0 If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Only used when svdmethod equals ‘randomized’
Attributes
components array ncomponents nfeatures Components with maximum variance
loglike list niterations The log likelihood at each iteration
noisevariance array shapenfeatures The estimated noise variance for each feature
niter int Number of iterations run
See also
PCA Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature This extra assumption makes probabilistic PCA faster as it can be computed in closed form
FastICA Independent component analysis a latent variable model with nonGaussian latent variables

winitNone randomstateNone
FastICA a fast algorithm for Independent Component Analysis
Read more in the User Guide
Parameters
ncomponents int optional Number of components to use If none is passed all are used
algorithm ‘parallel’ ‘deflation’ Apply parallel or deflational algorithm for FastICA
whiten boolean optional If whiten is false the data is already considered to be whitened and no whitening is performed
fun string or function optional Default ‘logcosh’ The functional form of the G function used in the approximation to negentropy Could be either ‘logcosh’ ‘exp’ or ‘cube’ You can also provide your own function It should return a tuple containing the value of the function and of its derivative in the point Example
def mygx return x 3 3 x 2meanaxis1
funargs dictionary optional Arguments to send to the functional form If empty and if fun’logcosh’ funargs will take value ‘alpha’ 10
maxiter int optional Maximum number of iterations during fit
tolfloat optional Tolerance on update at each iteration
winit None of an ncomponents ncomponents ndarray The mixing matrix to be used to initialize the algorithm
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
Attributes
components 2D array shape ncomponents nfeatures The unmixing matrix
mixing array shape nfeatures ncomponents The mixing matrix
niter int If the algorithm is “deflation” niter is the maximum number of iterations run across all components Else they are just the number of iterations taken to converge

694sklearndecomposition IncrementalPCA
classsklearndecomposition IncrementalPCA ncomponentsNone whitenFalse copyTrue
batchsizeNone
Incremental principal components analysis IPCA
Linear dimensionality reduction using Singular Value Decomposition of the data keeping only the most signif
icant singular vectors to project the data to a lower dimensional space The input data is centered but not scaled
for each feature before applying the SVD
Depending on the size of the input data this algorithm can be much more memory efficient than a PCA
This algorithm has constant memory complexity on the order of batchsize enabling use of npmemmap
files without loading the entire file into memory
The computational overhead of each SVD is Obatchsize nfeatures 2 but only 2
batchsize samples remain in memory at a time There will be nsamples batchsize SVD compu
tations to get the principal components versus 1 large SVD of complexity Onsamples nfeatures
2for PCA
Read more in the User Guide
Parameters
ncomponents int or None defaultNone Number of components to keep If
ncomponents is None thenncomponents is set tominnsamples
nfeatures
whiten bool optional When True False by default the components vectors are di
vided bynsamples timescomponents to ensure uncorrelated outputs with unit
componentwise variances
Whitening will remove some information from the transformed signal the relative variance
scales of the components but can sometimes improve the predictive accuracy of the down
stream estimators by making data respect some hardwired assumptions
copy bool defaultTrue If False X will be overwritten copyFalse can be used to save
memory but is unsafe for general use
batchsize int or None defaultNone The number of samples to use for each batch Only
used when calling fit Ifbatchsize isNone thenbatchsize is inferred from the
data and set to 5nfeatures to provide a balance between approximation accuracy
and memory consumption
Attributes
components array shape ncomponents nfeatures Components with maximum variance
explainedvariance array shape ncomponents Variance explained by each of the se
lected components
explainedvarianceratio array shape ncomponents Percentage of variance explained
by each of the selected components If all components are stored the sum of explained
variances is equal to 10
singularvalues array shape ncomponents The singular values corresponding to each
of the selected components The singular values are equal to the 2norms of the
ncomponents variables in the lowerdimensional space
mean array shape nfeatures Perfeature empirical mean aggregate over calls to
partialfit

var array shape nfeatures Perfeature empirical variance aggregate over calls to
partialfit

Returns
self object Returns the instance itself
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getcovariance self
Compute data covariance with the generative model
cov componentsT S2components sigma2 eyenfeatures
where S2 contains the explained variances and sigma2 contains the noise variances
Returns
cov array shapenfeatures nfeatures Estimated covariance of data

getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Compute data precision matrix with the generative model
Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency
Returns
precision array shapenfeatures nfeatures Estimated precision of data
inversetransform selfX
Transform data back to its original space
In other words return an input Xoriginal whose transform would be X
Parameters
Xarraylike shape nsamples ncomponents New data where nsamples is the number
of samples and ncomponents is the number of components
Returns
Xoriginal arraylike shape nsamples nfeatures
Notes
If whitening is enabled inversetransform will compute the exact inverse operation which includes re
versing whitening
partialfit selfXyNone checkinputTrue
Incremental fit with X All of X is processed as a single batch
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
checkinput bool Run checkarray on X
yIgnored
Returns
self object Returns the instance itself
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns

scikitlearn user guide Release 0213
self
transform selfX
Apply dimensionality reduction to X
X is projected on the first principal components previously extracted from a training set
Parameters
Xarraylike shape nsamples nfeatures New data where nsamples is the number of
samples and nfeatures is the number of features
Returns
Xnew arraylike shape nsamples ncomponents
Examples
import numpy as np
from sklearndecomposition import IncrementalPCA

Parameters
ncomponents int defaultNone Number of components If None all nonzero components
are kept
kernel "linear" "poly" "rbf" "sigmoid" "cosine" "precomputed" Kernel De
fault"linear"
gamma float default1nfeatures Kernel coefficient for rbf poly and sigmoid kernels Ig
nored by other kernels
degree int default3 Degree for poly kernels Ignored by other kernels
coef0 float default1 Independent term in poly and sigmoid kernels Ignored by other kernels

kernelparams mapping of string to any defaultNone Parameters keyword arguments and values for kernel passed as callable object Ignored by other kernels
alpha int default10 Hyperparameter of the ridge regression that learns the inverse transform when fitinversetransformTrue
fitinversetransform bool defaultFalse Learn the inverse transform for nonprecomputed kernels ie learn to find the preimage of a point
eigensolver string ‘auto’’dense’’arpack’ default’auto’ Select eigensolver to use If ncomponents is much less than the number of training samples arpack may be more effi cient than the dense eigensolver
tolfloat default0 Convergence tolerance for arpack If 0 optimal value will be chosen by arpack
maxiter int defaultNone Maximum number of iterations for arpack If None optimal value will be chosen by arpack
removezeroeig boolean defaultFalse If True then all components with zero eigenvalues are removed so that the number of components in the output may be ncomponents and sometimes even zero due to numerical instability When ncomponents is None this parameter is ignored and components with zero eigenvalues are removed regardless
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance ran domstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when eigensolver ‘arpack’
New in version 018
copyX boolean defaultTrue If True input X is copied and stored by the model in the Xfit attribute If no further changes will be done to X setting copyXFalse saves memory by storing a reference
New in version 018
njobs int or None optional defaultNone The number of parallel jobs to run None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
New in version 018
Attributes
lambdas array ncomponents Eigenvalues of the centered kernel matrix in decreasing order If ncomponents andremovezeroeig are not set then all values are stored
alphas array nsamples ncomponents Eigenvectors of the centered kernel matrix If ncomponents andremovezeroeig are not set then all components are stored
dualcoef array nsamples nfeatures Inverse transform matrix Only available when fitinversetransform is True
Xtransformedfit array nsamples ncomponents Projection of the fitted data on the kernel principal components Only available when fitinversetransform is True
Xfit nsamples nfeatures The data used to fit the model If copyXFalse then Xfit is a reference This attribute is used for the calls to transform

Latent Dirichlet Allocation with online variational Bayes algorithm
New in version 017
Read more in the User Guide
Parameters
ncomponents int optional default10 Number of topics
doctopicprior float optional defaultNone Prior of document topic distribution theta
If the value is None defaults to 1 ncomponents In1 this is called alpha
topicwordprior float optional defaultNone Prior of topic word distribution beta If
the value is None defaults to 1 ncomponents In1 this is called eta
learningmethod 'batch' 'online' default'batch' Method used to update component
Only used in fit method In general if the data size is large the online update will be
much faster than the batch update
Valid options
batch Batch variational Bayes method Use all training data in
each EM update
Old components will be overwritten in each iteration
online Online variational Bayes method In each EM update use
minibatch of training data to update the components
variable incrementally The learning rate is controlled by the
learningdecay and the learningoffset parameters
Changed in version 020 The default learning method is now batch
learningdecay float optional default07 It is a parameter that control learning rate in the
online learning method The value should be set between 05 10 to guarantee asymptotic
convergence When the value is 00 and batchsize is nsamples the update method is
same as batch learning In the literature this is called kappa
learningoffset float optional default10 A positive parameter that downweights early
iterations in online learning It should be greater than 10 In the literature this is called
tau0
maxiter integer optional default10 The maximum number of iterations
batchsize int optional default128 Number of documents to use in each EM iteration
Only used in online learning

evaluateevery int optional default0 How often to evaluate perplexity Only used in fit
method set it to 0 or negative number to not evalute perplexity in training at all Evaluating
perplexity can help you check convergence in training process but it will also increase total
training time Evaluating perplexity in every iteration might increase training time up to
twofold
totalsamples int optional default1e6 Total number of documents Only used in the
partialfit method
perptol float optional default1e1 Perplexity tolerance in batch learning Only used when
evaluateevery is greater than 0
meanchangetol float optional default1e3 Stopping tolerance for updating document
topic distribution in Estep
maxdocupdateiter int default100 Max number of iterations for updating document
topic distribution in the Estep
njobs int or None optional defaultNone The number of jobs to use in the Estep None
means 1 unless in a joblibparallelbackend context1means using all proces
sors See Glossary for more details
verbose int optional default0 Verbosity level
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Attributes
components array ncomponents nfeatures Variational parameters for topic word dis
tribution Since the complete conditional for topic word distribution is a Dirichlet
componentsi j can be viewed as pseudocount that represents the number of times
wordjwas assigned to topic i It can also be viewed as distribution over the words
for each topic after normalization modelcomponents modelcomponents
sumaxis1 npnewaxis
nbatchiter int Number of iterations of the EM step
niter int Number of passes over the dataset

subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyNone
Online VB with MiniBatch update
Parameters
Xarraylike or sparse matrix shapensamples nfeatures Document word matrix
yIgnored
Returns
self
perplexity selfXsubsamplingFalse
Calculate approximate perplexity for data X
Perplexity is defined as exp1 loglikelihood per word
Changed in version 019 doctopicdistr argument has been deprecated and is ignored because user no
longer has access to unnormalized distribution
Parameters
Xarraylike or sparse matrix nsamples nfeatures Document word matrix
subsampling bool Do subsampling or not
Returns
score float Perplexity score
scoreselfXyNone
Calculate approximate loglikelihood as score
Parameters
Xarraylike or sparse matrix shapensamples nfeatures Document word matrix
yIgnored
Returns
score float Use approximate bound as score
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

scikitlearn user guide Release 0213
transform selfX
Transform data X according to the fitted model
Changed in version 018 doctopicdistr is now normalized
Parameters
Xarraylike or sparse matrix shapensamples nfeatures Document word matrix
Returns
doctopicdistr shapensamples ncomponents Document topic distribution for X
Examples using sklearndecompositionLatentDirichletAllocation
•Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet Allocation

domstateNone alpha00 l1ratio00 verbose0 shuf
fleFalse
NonNegative Matrix Factorization NMF
Find two nonnegative matrices W H whose product approximates the non negative matrix X This factoriza
tion can be used for example for dimensionality reduction source separation or topic extraction
The objective function is
05X WHFro2
alpha l1ratio vecW1
alpha l1ratio vecH1
05alpha1 l1ratio WFro2
05alpha1 l1ratio HFro2
Where
AFro2 sumij Aij2 Frobenius norm
vecA1 sumij absAij Elementwise L1 norm
For multiplicativeupdate 'mu' solver the Frobenius norm 05 X WHFro2 can be changed into
another betadivergence loss by changing the betaloss parameter
The objective function is minimized with an alternating minimization of W and H
Read more in the User Guide
Parameters
ncomponents int or None Number of components if ncomponents is not set all features
are kept
init None 'random' 'nndsvd' 'nndsvda' 'nndsvdar' 'custom' Method used to initialize
the procedure Default None Valid options
•None 'nndsvd' if ncomponents minnsamples nfeatures otherwise random
•'random' nonnegative random matrices scaled with sqrtXmean
ncomponents
•'nndsvd' Nonnegative Double Singular Value Decomposition NNDSVD
initialization better for sparseness
•'nndsvda' NNDSVD with zeros filled with the average of X better when sparsity is
not desired
•'nndsvdar' NNDSVD with zeros filled with small random values generally faster
less accurate alternative to NNDSVDa for when sparsity is not desired
• 'custom' use custom matrices W and H
solver 'cd' 'mu' Numerical solver to use 'cd' is a Coordinate Descent solver 'mu' is a
Multiplicative Update solver
New in version 017 Coordinate Descent solver
New in version 019 Multiplicative Update solver

betaloss float or string default ‘frobenius’ String must be in ‘frobenius’ ‘kullbackleibler’ ‘itakurasaito’ Beta divergence to be minimized measuring the distance between X and the dot product WH Note that values different from ‘frobenius’ or 2 and ‘kullbackleibler’ or 1 lead to significantly slower fits Note that for betaloss 0 or ‘itakurasaito’ the input matrix X cannot contain zeros Used only in ‘mu’ solver
New in version 019
tolfloat default 1e4 Tolerance of the stopping condition
maxiter integer default 200 Maximum number of iterations before timing out
randomstate int RandomState instance or None optional default None If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
alpha double default 0 Constant that multiplies the regularization terms Set it to zero to have no regularization
New in version 017 alpha used in the Coordinate Descent solver
l1ratio double default 0 The regularization mixing parameter with 0 l1ratio 1 For l1ratio 0 the penalty is an elementwise L2 penalty aka Frobenius Norm For l1ratio 1 it is an elementwise L1 penalty For 0 l1ratio 1 the penalty is a combination of L1 and L2
New in version 017 Regularization parameter l1ratio used in the Coordinate Descent solver
verbose bool defaultFalse Whether to be verbose
shuffle boolean default False If true randomize the order of coordinates in the CD solver
New in version 017 shuffle parameter used in the Coordinate Descent solver
Attributes
components array ncomponents nfeatures Factorization matrix sometimes called ‘dic tionary’
reconstructionerr number Frobenius norm of the matrix difference or betadivergence between the training data Xand the reconstructed data WHfrom the fitted model
niter int Actual number of iterations

fittransform self X y W H Learn a NMF model for the data X and returns the trans
formed data
getparams self deep Get parameters for this estimator
inversetransform self W Transform data back to its original space
setparams self params Set the parameters of this estimator
transform self X Transform the data X according to the fitted NMF model
init selfncomponentsNone initNone solver’cd’ betaloss’frobenius’ tol00001
maxiter200 randomstateNone alpha00 l1ratio00 verbose0 shuffleFalse
fitselfXyNone params
Learn a NMF model for the data X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Data matrix to be decom
posed
yIgnored
Returns
self
fittransform selfXyNone WNone HNone
Learn a NMF model for the data X and returns the transformed data
This is more efficient than calling fit followed by transform
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Data matrix to be decom
posed
yIgnored
Warraylike shape nsamples ncomponents If init’custom’ it is used as initial guess
for the solution
Harraylike shape ncomponents nfeatures If init’custom’ it is used as initial guess
for the solution
Returns
Warray shape nsamples ncomponents Transformed data
getparams selfdeepTrue
Get parameters for this estimator
Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfW
Transform data back to its original space
Parameters
Warraylike sparse matrix shape nsamples ncomponents Transformed data matrix
Returns
Xarraylike sparse matrix shape nsamples nfeatures Data matrix of original shape
New in version 018
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform the data X according to the fitted NMF model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Data matrix to be trans
formed by the model
Returns
Warray shape nsamples ncomponents Transformed data
Examples using sklearndecompositionNMF
•Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet Allocation
•Selecting dimensionality reduction with Pipeline and GridSearchCV
•Faces dataset decompositions
6910sklearndecomposition PCA
classsklearndecomposition PCAncomponentsNone copyTrue whitenFalse
svdsolver’auto’ tol00 iteratedpower’auto’ ran
domstateNone
Principal component analysis PCA
Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimen
sional space The input data is centered but not scaled for each feature before applying the SVD
It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko
et al 2009 depending on the shape of the input data and the number of components to extract

It can also use the scipysparselinalg ARPACK implementation of the truncated SVD
Notice that this class does not support sparse input See TruncatedSVD for an alternative with sparse data
Read more in the User Guide
Parameters
ncomponents int float None or string Number of components to keep if ncomponents is
not set all components are kept
ncomponents minnsamples nfeatures
Ifncomponents mle andsvdsolver full Minka's MLE is used
to guess the dimension Use of ncomponents mle will interpret svdsolver
 auto assvdsolver full
If0 ncomponents 1 andsvdsolver full select the number of
components such that the amount of variance that needs to be explained is greater than the
percentage specified by ncomponents
Ifsvdsolver arpack the number of components must be strictly less than the
minimum of nfeatures and nsamples
Hence the None case results in
ncomponents minnsamples nfeatures 1
copy bool default True If False data passed to fit are overwritten and running
fitXtransformX will not yield the expected results use fittransformX instead
whiten bool optional default False When True False by default the components vectors
are multiplied by the square root of nsamples and then divided by the singular values to
ensure uncorrelated outputs with unit componentwise variances
Whitening will remove some information from the transformed signal the relative variance
scales of the components but can sometime improve the predictive accuracy of the down
stream estimators by making their data respect some hardwired assumptions
svdsolver string 'auto' 'full' 'arpack' 'randomized'
auto the solver is selected by a default policy based on Xshape andncomponents if
the input data is larger than 500x500 and the number of components to extract is lower
than 80 of the smallest dimension of the data then the more efficient 'randomized'
method is enabled Otherwise the exact full SVD is computed and optionally truncated
afterwards
full run exact full SVD calling the standard LAPACK solver via scipylinalgsvd
and select the components by postprocessing
arpack run SVD truncated to ncomponents calling ARPACK solver via scipy
sparselinalgsvds It requires strictly 0 ncomponents minXshape
randomized run randomized SVD by the method of Halko et al
New in version 0180
tolfloat 0 optional default 0 Tolerance for singular values computed by svdsolver
'arpack'
New in version 0180

iteratedpower int 0 or ‘auto’ default ‘auto’ Number of iterations for the power method computed by svdsolver ‘randomized’
New in version 0180
randomstate int RandomState instance or None optional default None If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when svdsolver ‘arpack’ or ‘randomized’
New in version 0180
Attributes
components array shape ncomponents nfeatures Principal axes in feature space rep resenting the directions of maximum variance in the data The components are sorted by explainedvariance
explainedvariance array shape ncomponents The amount of variance explained by each of the selected components
Equal to ncomponents largest eigenvalues of the covariance matrix of X
New in version 018
explainedvarianceratio array shape ncomponents Percentage of variance explained by each of the selected components
Ifncomponents is not set then all components are stored and the sum of the ratios is equal to 10
singularvalues array shape ncomponents The singular values corresponding to each of the selected components The singular values are equal to the 2norms of the ncomponents variables in the lowerdimensional space
New in version 019
mean array shape nfeatures Perfeature empirical mean estimated from the training set Equal toXmeanaxis0
ncomponents int The estimated number of components When ncomponents is set to ‘mle’ or a number between 0 and 1 with svdsolver ‘full’ this number is estimated from input data Otherwise it equals the parameter ncomponents or the lesser value of nfeatures and nsamples if ncomponents is None
noisevariance float The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999 See “Pattern Recognition and Machine Learning” by C Bishop 1221 p 574 or httpwwwmiketippingcompapersmetmppcapdf It is required to compute the estimated data covariance and score samples
Equal to the average of minnfeatures nsamples ncomponents smallest eigenvalues of the covariance matrix of X

Methods
fitself X y Fit the model with X
Continued on next page

Table 659 – continued from previous page

fittransform self X y	Fit the model with X and apply the dimensionality re duction on X
getcovariance self	Compute data covariance with the generative model
getparams self deep	Get parameters for this estimator
getprecision self	Compute data precision matrix with the generative model
inversetransform self X	Transform data back to its original space
score self X y	Return the average loglikelihood of all samples
scoresamples self X	Return the loglikelihood of each sample
setparams self params	Set the parameters of this estimator
transform self X	Apply dimensionality reduction to X

init selfncomponentsNone copyTrue whitenFalse svdsolver’auto’ tol00 iter atedpower’auto’ randomstateNone

fitselfXyNone

Fit the model with X

Parameters

Xarraylike shape nsamples nfeatures Training data where nsamples is the number of samples and nfeatures is the number of features

yIgnored

Returns

self object Returns the instance itself

fittransform selfXyNone

Fit the model with X and apply the dimensionality reduction on X

Parameters

Xarraylike shape nsamples nfeatures Training data where nsamples is the number of samples and nfeatures is the number of features

yIgnored

Returns

Xnew arraylike shape nsamples ncomponents

getcovariance self

Compute data covariance with the generative model

cov componentsT S2components sigma2 eyenfeatures

where S2 contains the explained variances and sigma2 contains the noise variances

Returns

cov array shapenfeatures nfeatures Estimated covariance of data

getparams selfdeepTrue

Get parameters for this estimator

Parameters

deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators

Returns

params mapping of string to any Parameter names mapped to their values
getprecision self
Compute data precision matrix with the generative model
Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency
Returns
precision array shapenfeatures nfeatures Estimated precision of data
inversetransform selfX
Transform data back to its original space
In other words return an input Xoriginal whose transform would be X
Parameters
Xarraylike shape nsamples ncomponents New data where nsamples is the number
of samples and ncomponents is the number of components
Returns
Xoriginal arraylike shape nsamples nfeatures
Notes
If whitening is enabled inversetransform will compute the exact inverse operation which includes re
versing whitening
scoreselfXyNone
Return the average loglikelihood of all samples
See “Pattern Recognition and Machine Learning” by C Bishop 1221 p 574 or httpwwwmiketipping
compapersmetmppcapdf
Parameters
Xarray shapensamples nfeatures The data
yIgnored
Returns
llfloat Average loglikelihood of the samples under the current model
scoresamples selfX
Return the loglikelihood of each sample
See “Pattern Recognition and Machine Learning” by C Bishop 1221 p 574 or httpwwwmiketipping
compapersmetmppcapdf
Parameters
Xarray shapensamples nfeatures The data
Returns
llarray shape nsamples Loglikelihood of each sample under the current model
setparams selfparams
Set the parameters of this estimator

The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object

Returns

self

transform selfX

Apply dimensionality reduction to X

X is projected on the first principal components previously extracted from a training set

Parameters

Xarraylike shape nsamples nfeatures New data where nsamples is the number of samples and nfeatures is the number of features

Returns

Xnew arraylike shape nsamples ncomponents

Examples

```
 import numpy as np
 from sklearndecomposition import IncrementalPCA
X  nparray1 1 2 1 3 2 1 1 2 1 3 2
ipca  IncrementalPCAncomponents2 batchsize3
ipcafitX
IncrementalPCAbatchsize3 copyTrue ncomponents2 whitenFalse
ipcatransformX
```

Examples using sklearndecompositionPCA

- Multilabel classification
- Explicit feature map approximation for RBF kernels
- Faces recognition example using eigenfaces and SVMs

Sparse Principal Components Analysis SparsePCA
Finds the set of sparse components that can optimally reconstruct the data The amount of sparseness is control
lable by the coefficient of the L1 penalty given by the parameter alpha
Read more in the User Guide
Parameters
ncomponents int Number of sparse atoms to extract
alpha float Sparsity controlling parameter Higher values lead to sparser components
ridgealpha float Amount of ridge shrinkage to apply in order to improve conditioning when
calling the transform method
maxiter int Maximum number of iterations to perform
tolfloat Tolerance for the stopping condition
method 'lars' 'cd' lars uses the least angle regression method to solve the lasso prob
lem linearmodellarspath cd uses the coordinate descent method to compute the Lasso
solution linearmodelLasso Lars will be faster if the estimated components are sparse
njobs int or None optional defaultNone Number of parallel jobs to run None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
Uinit array of shape nsamples ncomponents Initial values for the loadings for warm
restart scenarios
Vinit array of shape ncomponents nfeatures Initial values for the components for warm
restart scenarios
verbose int Controls the verbosity the higher the more messages Defaults to 0
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom

normalizecomponents boolean optional defaultFalse
• if False use a version of Sparse PCA without components normalization and without data centering This is likely a bug and even though it’s the default for backward compatibility this should not be used
• if True use a version of Sparse PCA with components normalization and data centering
New in version 020
Deprecated since version 022 normalizecomponents was added and set to False for backward compatibility It would be set to True from 022 onwards
Attributes
components array ncomponents nfeatures Sparse components extracted from the data
error array Vector of errors at each iteration
niter int Number of iterations run
mean array shape nfeatures Perfeature empirical mean estimated from the training set Equal toXmeanaxis0

Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Encode the data as a sparse combination of the dictionary atoms
Coding method is determined by the object parameter transformalgorithm
Parameters
Xarray of shape nsamples nfeatures Test data to be transformed must have the same
number of features as the data used to train the model
Returns
Xnew array shape nsamples ncomponents Transformed data
Examples using sklearndecompositionSparseCoder
•Sparse coding with a precomputed dictionary
6913sklearndecomposition TruncatedSVD
classsklearndecomposition TruncatedSVD ncomponents2 algorithm’randomized’
niter5 randomstateNone tol00
Dimensionality reduction using truncated SVD aka LSA
This transformer performs linear dimensionality reduction by means of truncated singular value decomposition
SVD Contrary to PCA this estimator does not center the data before computing the singular value decompo
sition This means it can work with scipysparse matrices efficiently
In particular truncated SVD works on term counttfidf matrices as returned by the vectorizers in
sklearnfeatureextractiontext In that context it is known as latent semantic analysis LSA
This estimator supports two algorithms a fast randomized SVD solver and a “naive” algorithm that uses
ARPACK as an eigensolver on X XT or XT X whichever is more efficient
Read more in the User Guide
Parameters

scikitlearn user guide Release 0213
ncomponents int default 2 Desired dimensionality of output data Must be strictly less
than the number of features The default value is useful for visualisation For LSA a value
of 100 is recommended
algorithm string default “randomized” SVD solver to use Either “arpack” for the
ARPACK wrapper in SciPy scipysparselinalgsvds or “randomized” for the randomized
algorithm due to Halko 2009
niter int optional default 5 Number of iterations for randomized SVD solver Not used
by ARPACK The default is larger than the default in randomizedsvd to handle sparse
matrices that may have large slowly decaying spectrum
randomstate int RandomState instance or None optional default None If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
tolfloat optional Tolerance for ARPACK 0 means machine precision Ignored by random
ized SVD solver
Attributes
components array shape ncomponents nfeatures
explainedvariance array shape ncomponents The variance of the training samples
transformed by a projection to each component
explainedvarianceratio array shape ncomponents Percentage of variance explained
by each of the selected components
singularvalues array shape ncomponents The singular values corresponding to each
of the selected components The singular values are equal to the 2norms of the
ncomponents variables in the lowerdimensional space
See also
PCA
Notes
SVD suffers from a problem called “sign indeterminacy” which means the sign of the components and the
output from transform depend on the algorithm and random state To work around this fit instances of this class
to data once then keep the instance around to do transformations

dictinit array of shape ncomponents nfeatures Initial value for the dictionary for warm
restart scenarios

callback callable or None optional default None callable that gets invoked every five iter
ations
batchsize int The number of samples to take in each batch
verbose bool optional default False To control the verbosity of the procedure
shuffle boolean Whether to shuffle the data before splitting it in batches
njobs int or None optional defaultNone Number of parallel jobs to run None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
method ‘lars’ ‘cd’ lars uses the least angle regression method to solve the lasso prob
lem linearmodellarspath cd uses the coordinate descent method to compute the Lasso
solution linearmodelLasso Lars will be faster if the estimated components are sparse
iteroffset int default 0 Number of previous iterations completed on the dictionary used for
initialization
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
returninnerstats boolean optional Return the inner statistics A dictionary covariance
and B data approximation Useful to restart the algorithm in an online setting If re
turninnerstats is True returncode is ignored
innerstats tuple of A B ndarrays Inner sufficient statistics that are kept by the algorithm
Passing them at initialization is useful in online settings to avoid loosing the history of
the evolution A ncomponents ncomponents is the dictionary covariance matrix B
nfeatures ncomponents is the data approximation matrix
returnniter bool Whether or not to return the number of iterations
positivedict bool Whether to enforce positivity when finding the dictionary
New in version 020
positivecode bool Whether to enforce positivity when finding the code
New in version 020
Returns
code array of shape nsamples ncomponents the sparse code only returned if
returncodeTrue
dictionary array of shape ncomponents nfeatures the solutions to the dictionary learning
problem
niter int Number of iterations run Returned only if returnniter is set toTrue

6916sklearndecomposition fastica
sklearndecomposition fasticaXncomponentsNone algorithm’parallel’ whitenTrue
fun’logcosh’ funargsNone maxiter200 tol00001
winitNone randomstateNone returnXmeanFalse
computesourcesTrue returnniterFalse
Perform Fast Independent Component Analysis
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures Training vector where nsamples is the number of samples and nfeatures is the number of features
ncomponents int optional Number of components to extract If None no dimension reduction is performed
algorithm ‘parallel’ ‘deflation’ optional Apply a parallel or deflational FASTICA algorithm
whiten boolean optional If True perform an initial whitening of the data If False the data is assumed to have already been preprocessed it should be centered normed and white Otherwise you will get incorrect results In this case the parameter ncomponents will be ignored
fun string or function optional Default ‘logcosh’ The functional form of the G function used in the approximation to negentropy Could be either ‘logcosh’ ‘exp’ or ‘cube’ You can also provide your own function It should return a tuple containing the value of the function and of its derivative in the point The derivative should be averaged along its last dimension Example
def mygx return x 3 npmean3 x 2 axis1
funargs dictionary optional Arguments to send to the functional form If empty or None and if fun’logcosh’ funargs will take value ‘alpha’ 10
maxiter int optional Maximum number of iterations to perform
tolfloat optional A positive scalar giving the tolerance at which the unmixing matrix is considered to have converged
winit ncomponents ncomponents array optional Initial unmixing array of dimension ncompncomp If None default then an array of normal rv’s is used
randomstate int RandomState instance or None optional defaultNone If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
returnXmean bool optional If True Xmean is returned too
computesources bool optional If False sources are not computed but only the rotation matrix This can save memory when working with big data Defaults to True
returnniter bool optional Whether or not to return the number of iterations
Returns
Karray shape ncomponents nfeatures None If whiten is ‘True’ K is the prewhitening matrix that projects data onto the first ncomponents principal components If whiten is ‘False’ K is ‘None’

Warray shape ncomponents ncomponents Estimated unmixing matrix The mixing
matrix can be obtained by
w npdotW KT
A wT wwTI
Sarray shape nsamples ncomponents None Estimated source matrix
Xmean array shape nfeatures The mean over features Returned only if returnXmean
is True
niter int If the algorithm is “deflation” niter is the maximum number of iterations run
across all components Else they are just the number of iterations taken to converge This is
returned only when returnniter is set to True
Notes
The data matrix X is considered to be a linear combination of nonGaussian independent components ie X
 AS where columns of S contain the independent components and A is a linear mixing matrix In short ICA
attempts to unmix the data by estimating an unmixing matrix W where S W
K X
This implementation was originally made for data of shape nfeatures nsamples Now the input is transposed
before the algorithm is applied This makes it slightly faster for Fortranordered input
Implemented using FastICA A Hyvarinen and E Oja Independent Component Analysis Algorithms and
Applications Neural Networks 1345 2000 pp 411430
6917sklearndecomposition nonnegativefactorization
sklearndecomposition nonnegativefactorization X WNone HNone

updateHTrue solver’cd’
betaloss’frobenius’ tol00001
maxiter200 alpha00
l1ratio00 regularizationNone
randomstateNone verbose0
shuffleFalse
Compute Nonnegative Matrix Factorization NMF
Find two nonnegative matrices W H whose product approximates the non negative matrix X This factoriza
tion can be used for example for dimensionality reduction source separation or topic extraction
The objective function is
05X WHFro2
 alpha l1ratio vecW1
 alpha l1ratio vecH1
 05alpha1 l1ratio WFro2
 05alpha1 l1ratio HFro2
Where
AFro2 sumij Aij2 Frobenius norm
vecA1 sumij absAij Elementwise L1 norm

For multiplicativeupdate ‘mu’ solver the Frobenius norm 05 X WHFro2 can be changed into another betadivergence loss by changing the betaloss parameter
The objective function is minimized with an alternating minimization of W and H If H is given and up dateHFalse it solves for W only
Parameters
Xarraylike shape nsamples nfeatures Constant matrix
Warraylike shape nsamples ncomponents If init’custom’ it is used as initial guess for the solution
Harraylike shape ncomponents nfeatures If init’custom’ it is used as initial guess for the solution If updateHFalse it is used as a constant to solve for W only
ncomponents integer Number of components if ncomponents is not set all features are kept
init None ‘random’ ‘nndsvd’ ‘nndsvda’ ‘nndsvdar’ ‘custom’ Method used to initialize the procedure Default ‘random’
The default value will change from ‘random’ to None in version 023 to make it consistent with decompositionNMF
Valid options
• None ‘nndsvd’ if ncomponents nfeatures otherwise ‘random’
•‘random’ nonnegative random matrices scaled with sqrtXmean ncomponents
•‘nndsvd’ Nonnegative Double Singular Value Decomposition NNDSVD initialization better for sparseness
•‘nndsvda’ NNDSVD with zeros filled with the average of X better when sparsity is not desired
•‘nndsvdar’ NNDSVD with zeros filled with small random values generally faster less accurate alternative to NNDSVDa for when sparsity is not desired
• ‘custom’ use custom matrices W and H
updateH boolean default True Set to True both W and H will be estimated from initial guesses Set to False only W will be estimated
solver ‘cd’ ‘mu’ Numerical solver to use ‘cd’ is a Coordinate Descent solver that uses Fast Hierarchical
Alternating Least Squares Fast HALS
‘mu’ is a Multiplicative Update solver
New in version 017 Coordinate Descent solver
New in version 019 Multiplicative Update solver
betaloss float or string default ‘frobenius’ String must be in ‘frobenius’ ‘kullbackleibler’ ‘itakurasaito’ Beta divergence to be minimized measuring the distance between X and the dot product WH Note that values different from ‘frobenius’ or 2 and ‘kullbackleibler’ or 1 lead to significantly slower fits Note that for betaloss 0 or ‘itakurasaito’ the input matrix X cannot contain zeros Used only in ‘mu’ solver
New in version 019
tolfloat default 1e4 Tolerance of the stopping condition

scikitlearn user guide Release 0213
maxiter integer default 200 Maximum number of iterations before timing out
alpha double default 0 Constant that multiplies the regularization terms
l1ratio double default 0 The regularization mixing parameter with 0 l1ratio 1 For
l1ratio 0 the penalty is an elementwise L2 penalty aka Frobenius Norm For l1ratio
1 it is an elementwise L1 penalty For 0 l1ratio 1 the penalty is a combination of L1
and L2
regularization ‘both’ ‘components’ ‘transformation’ None Select whether the regulariza
tion affects the components H the transformation W both or none of them
randomstate int RandomState instance or None optional default None If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
verbose integer default 0 The verbosity level
shuffle boolean default False If true randomize the order of coordinates in the CD solver
Returns
Warraylike shape nsamples ncomponents Solution to the nonnegative least squares
problem
Harraylike shape ncomponents nfeatures Solution to the nonnegative least squares
problem
niter int Actual number of iterations

Linear Discriminant Analysis
A classifier with a linear decision boundary generated by fitting class conditional densities to the data and using
Bayes' rule
The model fits a Gaussian density to each class assuming that all classes share the same covariance matrix
The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discrim
inative directions
New in version 017 LinearDiscriminantAnalysis
Read more in the User Guide
Parameters
solver string optional
Solver to use possible values
• 'svd' Singular value decomposition default Does not compute the covariance ma
trix therefore this solver is recommended for data with a large number of features
• 'lsqr' Least squares solution can be combined with shrinkage
• 'eigen' Eigenvalue decomposition can be combined with shrinkage
shrinkage string or float optional
Shrinkage parameter possible values

• None no shrinkage default
• ‘auto’ automatic shrinkage using the LedoitWolf lemma
• float between 0 and 1 fixed shrinkage parameter
Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers
priors array optional shape nclasses Class priors
ncomponents int optional defaultNone Number of components minnclasses
1 nfeatures for dimensionality reduction If None will be set to minnclasses 1
nfeatures
storecovariance bool optional Additionally compute class covariance matrix default
False used only in ‘svd’ solver
New in version 017
tolfloat optional default 10e4 Threshold used for rank estimation in SVD solver
New in version 017
Attributes
coef array shape nfeatures or nclasses nfeatures Weight vectors
intercept array shape nfeatures Intercept term
covariance arraylike shape nfeatures nfeatures Covariance matrix shared by all
classes
explainedvarianceratio array shape ncomponents Percentage of variance explained
by each of the selected components If ncomponents is not set then all components are
stored and the sum of explained variances is equal to 10 Only available when eigen or svd
solver is used
means arraylike shape nclasses nfeatures Class means
priors arraylike shape nclasses Class priors sum to 1
scalings arraylike shape rank nclasses 1 Scaling of the features in the space spanned
by the class centroids
xbar arraylike shape nfeatures Overall mean
classes arraylike shape nclasses Unique class labels
See also

nant Analysis
Notes
The default solver is ‘svd’ It can perform both classification and transform and it does not rely on the calcu
lation of the covariance matrix This can be an advantage in situations where the number of features is large
However the ‘svd’ solver cannot be used with shrinkage
The ‘lsqr’ solver is an efficient algorithm that only works for classification It supports shrinkage
The ‘eigen’ solver is based on the optimization of the between class scatter to within class scatter ratio It can
be used for both classification and transform and it supports shrinkage However the ‘eigen’ solver needs to
compute the covariance matrix so it might not be suitable for situations with a high number of features

Examples
```
 import numpy as np

labels
setparams self params Set the parameters of this estimator
transform self X Project data to maximize class separation
init self solver'svd' shrinkageNone priorsNone ncomponentsNone
storecovarianceFalse tol00001
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
fitselfXy
Fit LinearDiscriminantAnalysis model according to the given training data and parameters
Changed in version 019 storecovariance has been moved to main constructor
Changed in version 019 tolhas been moved to main constructor
Parameters
Xarraylike shape nsamples nfeatures Training data

yarray shape nsamples Target values
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
predictlogproba selfX
Estimate log probability
Parameters
Xarraylike shape nsamples nfeatures Input data
Returns
Carray shape nsamples nclasses Estimated log probabilities
predictproba selfX
Estimate probability
Parameters
Xarraylike shape nsamples nfeatures Input data
Returns
Carray shape nsamples nclasses Estimated probabilities
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted

Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
transform selfX
Project data to maximize class separation
Parameters
Xarraylike shape nsamples nfeatures Input data
Returns
Xnew array shape nsamples ncomponents Transformed data
Examples using sklearndiscriminantanalysisLinearDiscriminantAnalysis
•Normal and Shrinkage Linear Discriminant Analysis for classification
•Linear and Quadratic Discriminant Analysis with covariance ellipsoid

Quadratic Discriminant Analysis
A classifier with a quadratic decision boundary generated by fitting class conditional densities to the data and using Bayes’ rule
The model fits a Gaussian density to each class
New in version 017 QuadraticDiscriminantAnalysis
Read more in the User Guide
Parameters

priors array optional shape nclasses Priors on classes
regparam float optional Regularizes the covariance estimate as
1regparam Sigma regparam npeyenfeatures
storecovariance boolean If True the covariance matrices are computed and stored in the
selfcovariance attribute
New in version 017
tolfloat optional default 10e4 Threshold used for rank estimation
New in version 017
Attributes
covariance list of arraylike shape nfeatures nfeatures Covariance matrices of each
class
means arraylike shape nclasses nfeatures Class means
priors arraylike shape nclasses Class priors sum to 1
rotations list of arrays For each class k an array of shape nfeatures nk with nk
minnfeatures number of elements in class k It is the rotation of the
Gaussian distribution ie its principal axis
scalings list of arrays For each class k an array of shape nk It contains the scaling of the
Gaussian distributions along its principal axes ie the variance in the rotated coordinate
system

init selfpriorsNone regparam00 storecovarianceFalse tol00001
decisionfunction selfX
Apply decision function to an array of samples
Parameters
Xarraylike shape nsamples nfeatures Array of samples test vectors
Returns
Carray shape nsamples nclasses or nsamples Decision function values related
to each class per sample In the twoclass case the shape is nsamples giving the log
likelihood ratio of the positive class
fitselfXy
Fit the model according to the given training data and parameters
Changed in version 019 storecovariances has been moved to main constructor as
storecovariance
Changed in version 019 tol has been moved to main constructor
Parameters
Xarraylike shape nsamples nfeatures Training vector where nsamples is the
number of samples and nfeatures is the number of features
yarray shape nsamples Target values integers
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Perform classification on an array of test vectors X
The predicted class C for each sample in X is returned
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carray shape nsamples

predictlogproba selfX
Return posterior probabilities of classification
Parameters
Xarraylike shape nsamples nfeatures Array of samplestest vectors
Returns
Carray shape nsamples nclasses Posterior logprobabilities of classification per
class
predictproba selfX
Return posterior probabilities of classification
Parameters
Xarraylike shape nsamples nfeatures Array of samplestest vectors
Returns
Carray shape nsamples nclasses Posterior probabilities of classification per class
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

ing simple rules
dummyDummyRegressor strategy constant DummyRegressor is a regressor that makes predictions us
ing simple rules
6111sklearndummy DummyClassifier
classsklearndummy DummyClassifier strategy’stratified’ randomstateNone constantNone
DummyClassifier is a classifier that makes predictions using simple rules
This classifier is useful as a simple baseline to compare with other real classifiers Do not use it for real
problems
Read more in the User Guide
Parameters
strategy str default”stratified” Strategy to use to generate predictions
• “stratified” generates predictions by respecting the training set’s class distribution
• “mostfrequent” always predicts the most frequent label in the training set
• “prior” always predicts the class that maximizes the class prior like “mostfrequent”
andpredictproba returns the class prior
• “uniform” generates predictions uniformly at random
• “constant” always predicts a constant label that is provided by the user This is useful for
metrics that evaluate a nonmajority class
New in version 017 Dummy Classifier now supports prior fitting strategy using param
eterprior
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
constant int or str or array of shape noutputs The explicit constant as predicted by the
“constant” strategy This parameter is useful only for the “constant” strategy
Attributes
classes array or list of array of shape nclasses Class labels for each output
nclasses array or list of array of shape nclasses Number of label for each output
classprior array or list of array of shape nclasses Probability of each class for each
output
noutputs int Number of outputs
sparseoutput bool True if the array returned from predict is to be in sparse CSC format
Is automatically set to True if the input y is passed in sparse format
Methods

fitself X y sampleweight Fit the random classifier
getparams self deep Get parameters for this estimator
predict self X Perform classification on test vectors X
predictlogproba self X Return log probability estimates for the test vectors X
predictproba self X Return probability estimates for the test vectors X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfstrategy'stratified' randomstateNone constantNone
fitselfXysampleweightNone
Fit the random classifier
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples
yarraylike shape nsamples or nsamples noutputs Target values
sampleweight arraylike of shape nsamples optional Sample weights
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Perform classification on test vectors X
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples
Returns
yarray shape nsamples or nsamples noutputs Predicted target values for X
predictlogproba selfX
Return log probability estimates for the test vectors X
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples
Returns
Parraylike or list of arraylike of shape nsamples nclasses Returns the log proba
bility of the sample for each class in the model where classes are ordered arithmetically
for each output

predictproba selfX
Return probability estimates for the test vectors X
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples
Returns
Parraylike or list of arraylke of shape nsamples nclasses Returns the probability
of the sample for each class in the model where classes are ordered arithmetically for
each output
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike None Test samples with shape nsamples nfeatures or None Passing
None as test samples gives the same result as passing real test samples since DummyClas
sifier operates independently of the sampled observations
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
6112sklearndummy DummyRegressor
classsklearndummy DummyRegressor strategy’mean’ constantNone quantileNone
DummyRegressor is a regressor that makes predictions using simple rules
This regressor is useful as a simple baseline to compare with other real regressors Do not use it for real
problems
Read more in the User Guide
Parameters
strategy str Strategy to use to generate predictions
• “mean” always predicts the mean of the training set
• “median” always predicts the median of the training set
• “quantile” always predicts a specified quantile of the training set provided with the
quantile parameter

• “constant” always predicts a constant value that is provided by the user
constant int or float or array of shape noutputs The explicit constant as predicted by the
“constant” strategy This parameter is useful only for the “constant” strategy
quantile float in 00 10 The quantile to predict using the “quantile” strategy A quantile of
05 corresponds to the median while 00 to the minimum and 10 to the maximum
Attributes
constant float or array of shape noutputs Mean or median or quantile of the training tar
gets or constant value given by the user
noutputs int Number of outputs
Methods
fitself X y sampleweight Fit the random regressor
getparams self deep Get parameters for this estimator
predict self X returnstd Perform classification on test vectors X
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfstrategy’mean’ constantNone quantileNone
fitselfXysampleweightNone
Fit the random regressor
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples
yarraylike shape nsamples or nsamples noutputs Target values
sampleweight arraylike of shape nsamples optional Sample weights
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfXreturnstdFalse
Perform classification on test vectors X
Parameters
Xarraylike object with finite length or shape Training data requires length
nsamples

returnstd boolean optional Whether to return the standard deviation of posterior predic
tion All zeros in this case
Returns
yarray shape nsamples or nsamples noutputs Predicted target values for X
ystd array shape nsamples or nsamples noutputs Standard deviation of predic
tive distribution of query points
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike None Test samples with shape nsamples nfeatures or None For
some estimators this may be a precomputed kernel matrix instead shape nsamples
nsamplesfitted where nsamplesfitted is the number of samples used in the fitting
for the estimator Passing None as test samples gives the same result as passing real test
samples since DummyRegressor operates independently of the sampled observations
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

An AdaBoost classifier
An AdaBoost 1 classifier is a metaestimator that begins by fitting a classifier on the original dataset and then
fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances
are adjusted such that subsequent classifiers focus more on difficult cases
This class implements the algorithm known as AdaBoostSAMME 2
Read more in the User Guide
Parameters
baseestimator object optional defaultNone The base estimator from which the boosted
ensemble is built Support for sample weighting is required as well as proper
classes andnclasses attributes If None then the base estimator is
DecisionTreeClassifiermaxdepth1
nestimators integer optional default50 The maximum number of estimators at which
boosting is terminated In case of perfect fit the learning procedure is stopped early
learningrate float optional default1 Learning rate shrinks the contribution of each
classifier by learningrate There is a tradeoff between learningrate and
nestimators
algorithm 'SAMME' 'SAMMER' optional default'SAMMER' If 'SAMMER' then
use the SAMMER real boosting algorithm baseestimator must support calculation
of class probabilities If 'SAMME' then use the SAMME discrete boosting algorithm The
SAMMER algorithm typically converges faster than SAMME achieving a lower test error
with fewer boosting iterations
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance

randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Attributes
estimators list of classifiers The collection of fitted subestimators

ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are
converted to CSR
Returns
yarray of shape nsamples The predicted classes
predictlogproba selfX
Predict class logprobabilities for X
The predicted class logprobabilities of an input sample is computed as the weighted mean predicted class
logprobabilities of the classifiers in the ensemble
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are
converted to CSR
Returns
parray of shape nsamples nclasses The class probabilities of the input samples The
order of outputs is the same of that of the classes attribute
predictproba selfX
Predict class probabilities for X
The predicted class probabilities of an input sample is computed as the weighted mean predicted class
probabilities of the classifiers in the ensemble
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are
converted to CSR
Returns
parray of shape nsamples nclasses The class probabilities of the input samples The
order of outputs is the same of that of the classes attribute
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples

yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
stageddecisionfunction selfX
Compute decision function of Xfor each boosting iteration
This method allows monitoring ie determine error on testing set after each boosting iteration
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are converted to CSR
Returns
score generator of array shape nsamples k The decision function of the input sam ples The order of outputs is the same of that of the classes attribute Binary classification is a special cases with k 1 otherwise knclasses For binary classification values closer to 1 or 1 mean more like the first or second class in classes respectively
stagedpredict selfX
Return staged predictions for X
The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble
This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring such as to determine the prediction on a test set after each boost
Parameters
Xarraylike of shape nsamples nfeatures The input samples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are converted to CSR
Returns
ygenerator of array shape nsamples The predicted classes
stagedpredictproba selfX
Predict class probabilities for X
The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble
This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring such as to determine the predicted class probabilities on a test set after each boost
Parameters

Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are
converted to CSR
Returns
pgenerator of array shape nsamples The class probabilities of the input samples The
order of outputs is the same of that of the classes attribute
stagedscore selfXysampleweightNone
Return staged scores for X y
This generator method yields the ensemble score after each iteration of boosting and therefore allows
monitoring such as to determine the score on a test set after each boost
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrix can be CSC CSR COO DOK or LIL COO DOK and LIL are
converted to CSR
yarraylike shape nsamples Labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
zfloat

be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object

classsklearnensemble BaggingClassifier baseestimatorNone nestimators10 maxsamples10 maxfeatures10 boot
strapTrue bootstrapfeaturesFalse
oobscoreFalse warmstartFalse njobsNone
randomstateNone verbose0
A Bagging classifier
A Bagging classifier is an ensemble metaestimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions either by voting or by averaging to form a final prediction Such a metaestimator can typically be used as a way to reduce the variance of a blackbox estimator eg a decision tree by introducing randomization into its construction procedure and then making an ensemble out of it
This algorithm encompasses several works from the literature When random subsets of the dataset are drawn as random subsets of the samples then this algorithm is known as Pasting Rb1846455d0e51 If samples are drawn with replacement then the method is known as Bagging Rb1846455d0e52 When random subsets of the dataset are drawn as random subsets of the features then the method is known as Random Subspaces Rb1846455d0e53 Finally when base estimators are built on subsets of both samples and features then the method is known as Random Patches Rb1846455d0e54
Read more in the User Guide
Parameters
baseestimator object or None optional defaultNone The base estimator to fit on random subsets of the dataset If None then the base estimator is a decision tree
nestimators int optional default10 The number of base estimators in the ensemble
maxsamples int or float optional default10 The number of samples to draw from X to train each base estimator
• If int then draw maxsamples samples
• If float then draw maxsamples Xshape0 samples

maxfeatures int or float optional default10 The number of features to draw from X to train each base estimator
• If int then draw maxfeatures features
• If float then draw maxfeatures Xshape1 features
bootstrap boolean optional defaultTrue Whether samples are drawn with replacement If False sampling without replacement is performed
bootstrapfeatures boolean optional defaultFalse Whether features are drawn with replacement
oobscore bool optional defaultFalse Whether to use outofbag samples to estimate the generalization error
warmstart bool optional defaultFalse When set to True reuse the solution of the previous call to fit and add more estimators to the ensemble otherwise just fit a whole new ensemble See the Glossary
New in version 017 warmstart constructor parameter
njobs int or None optional defaultNone The number of jobs to run in parallel for both fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity when fitting and predicting
Attributes
baseestimator estimator The base estimator from which the ensemble is grown
estimators list of estimators The collection of fitted base estimators
estimatorssamples list of arrays The subset of drawn samples for each base estimator
estimatorsfeatures list of arrays The subset of drawn features for each base estimator
classes array of shape nclasses The classes labels
nclasses int or list The number of classes
oobscore float Score of the training dataset obtained using an outofbag estimate
oobdecisionfunction array of shape nsamples nclasses Decision function computed with outofbag estimate on the training set If nestimators is small it might be possible that a data point was never left out during the bootstrap In this case oobdecisionfunction might contain NaN

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class for X
The predicted class of an input sample is computed as the class with the highest mean predicted probability
If base estimators do not implement a predictproba method then it resorts to voting
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrices are accepted only if they are supported by the base estimator
Returns
yarray of shape nsamples The predicted classes
predictlogproba selfX
Predict class logprobabilities for X
The predicted class logprobabilities of an input sample is computed as the log of the mean predicted class
probabilities of the base estimators in the ensemble
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrices are accepted only if they are supported by the base estimator
Returns
parray of shape nsamples nclasses The class logprobabilities of the input samples
The order of the classes corresponds to that in the attribute classes
predictproba selfX
Predict class probabilities for X
The predicted class probabilities of an input sample is computed as the mean predicted class probabilities
of the base estimators in the ensemble If base estimators do not implement a predictproba method
then it resorts to voting and the predicted class probabilities of an input sample represents the proportion
of estimators predicting each class
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The training input sam
ples Sparse matrices are accepted only if they are supported by the base estimator
Returns
parray of shape nsamples nclasses The class probabilities of the input samples The
order of the classes corresponds to that in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted

Parameters
Xarraylike shape nsamples nfeatures Test samples

score float R2 of selfpredictX wrt y

Notes

The R2 score used when calling score on a regressor will use multioutputuniformaverage from version 023 to keep consistent with metricsr2score This will influence the score method of all the multioutput regressors except for multioutputMultiOutputRegressor To specify the default value manually and avoid the warning please either call metricsr2score directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses multioutputuniformaverage

setparams selfparams

Set the parameters of this estimator

The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object

Returns

self

Examples using sklearnensembleBaggingRegressor

•Single estimator versus bagging biasvariance decomposition

6125sklearnensemble IsolationForest

classsklearnensemble IsolationForest nestimators100 maxsamples’auto’ contamination’legacy’ maxfeatures10 bootstrapFalse njobsNone behaviour’old’ randomstateNone verbose0 warmstartFalse

Isolation Forest Algorithm

Return the anomaly score of each sample using the IsolationForest algorithm

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature

Since recursive partitioning can be represented by a tree structure the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node

This path length averaged over a forest of such random trees is a measure of normality and our decision function

Random partitioning produces noticeably shorter paths for anomalies Hence when a forest of random trees collectively produce shorter path lengths for particular samples they are highly likely to be anomalies
Read more in the User Guide
New in version 018
Parameters
nestimators int optional default100 The number of base estimators in the ensemble
maxsamples int or float optional default”auto”
The number of samples to draw from X to train each base estimator
• If int then draw maxsamples samples
• If float then draw maxsamples Xshape0 samples
• If “auto” then maxsamplesmin256 nsamples
If maxsamples is larger than the number of samples provided all samples will be used for all trees no sampling
contamination float in 0 05 optional default01 The amount of contamination of the data set ie the proportion of outliers in the data set Used when fitting to define the threshold on the decision function If ‘auto’ the decision function threshold is determined as in the original paper
Changed in version 020 The default value of contamination will change from 01 in 020 toauto in 022
maxfeatures int or float optional default10 The number of features to draw from X to train each base estimator
• If int then draw maxfeatures features
• If float then draw maxfeatures Xshape1 features
bootstrap boolean optional defaultFalse If True individual trees are fit on random subsets of the training data sampled with replacement If False sampling without replacement is performed
njobs int or None optional defaultNone The number of jobs to run in parallel for both fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
behaviour str default’old’ Behaviour of the decisionfunction which can be ei ther ‘old’ or ‘new’ Passing behaviournew makes the decisionfunction
change to match other anomaly detection algorithm API which will be the default be haviour in the future As explained in details in the offset attribute documentation thedecisionfunction becomes dependent on the contamination parameter in such a way that 0 becomes its natural threshold to detect outliers
New in version 020 behaviour is added in 020 for backcompatibility purpose
Deprecated since version 020 behaviourold is deprecated in 020 and will not be possible in 022
Deprecated since version 022 behaviour parameter will be deprecated in 022 and re moved in 024
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance

randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity of the tree building process
warmstart bool optional defaultFalse When set to True reuse the solution of the pre
vious call to fit and add more estimators to the ensemble otherwise just fit a whole new
forest See the Glossary
New in version 021
Attributes
estimators list of DecisionTreeClassifier The collection of fitted subestimators
estimatorssamples list of arrays The subset of drawn samples for each base estima
tor
maxsamples integer The actual number of samples
offset float Offset used to define the decision function from the raw scores We have the
relationdecisionfunction scoresamples offset Assuming be
haviour ‘new’ offset is defined as follows When the contamination parameter
is set to “auto” the offset is equal to 05 as the scores of inliers are close to 0 and the
scores of outliers are close to 1 When a contamination parameter different than “auto”
is provided the offset is defined in such a way we obtain the expected number of outliers
samples with decision function 0 in training Assuming the behaviour parameter is set
to ‘old’ we always have offset 05 making the decision function independent
from the contamination parameter
Notes
The implementation is based on an ensemble of ExtraTreeRegressor The maximum depth of each tree is set to
ceillog2n where is the number of samples used to build the tree see Liu et al 2008 for more

decisionfunction selfX
Average anomaly score of X of the base classifiers
The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest
The measure of normality of an observation given a tree is the depth of the leaf containing this observation
which is equivalent to the number of splittings required to isolate this point In case of several observations
nleft in the leaf the average path length of a nleft samples isolation tree is added
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally
it will be converted to dtypenpfloat32 and if a sparse matrix is provided to a sparse
csrmatrix
Returns
scores array shape nsamples The anomaly score of the input samples The lower the
more abnormal Negative scores represent outliers positive scores represent inliers
estimatorssamples
The subset of drawn samples for each base estimator
Returns a dynamically generated list of indices identifying the samples used for fitting each member of the
ensemble ie the inbag samples
Note the list is recreated at each call to the property in order to reduce the object memory footprint by
not storing the sampling data Thus fetching the property may be slower than expected
fitselfXyNone sampleweightNone
Fit estimator
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Use
dtypenpfloat32 for maximum efficiency Sparse matrices are also supported use
sparsecscmatrix for maximum efficiency
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted
yIgnored not used present for API consistency by convention
Returns
self object
fitpredict selfXyNone
Performs fit on X and returns labels for X
Returns 1 for outliers and 1 for inliers
Parameters
Xndarray shape nsamples nfeatures Input data
yIgnored not used present for API consistency by convention
Returns
yndarray shape nsamples 1 for inliers 1 for outliers
getparams selfdeepTrue
Get parameters for this estimator
Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict if a particular sample is an outlier or not
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally
it will be converted to dtypenpfloat32 and if a sparse matrix is provided to a sparse
csrmatrix
Returns
isinlier array shape nsamples For each observation tells whether or not 1 or 1 it
should be considered as an inlier according to the fitted model
scoresamples selfX
Opposite of the anomaly score defined in the original paper
The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest
The measure of normality of an observation given a tree is the depth of the leaf containing this observation
which is equivalent to the number of splittings required to isolate this point In case of several observations
nleft in the leaf the average path length of a nleft samples isolation tree is added
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples
Returns
scores array shape nsamples The anomaly score of the input samples The lower the
more abnormal
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

maxleafnodesNone
minimpuritydecrease00
minimpuritysplitNone sparseoutputTrue
njobsNone randomstateNone verbose0
warmstartFalse
An ensemble of totally random trees
An unsupervised transformation of a dataset to a highdimensional sparse representation A datapoint is coded according to which leaf of each tree it is sorted into Using a onehot encoding of the leaves this leads to a binary coding with as many ones as there are trees in the forest
The dimensionality of the resulting representation is nout nestimators maxleafnodes Ifmaxleafnodes None the number of leaf nodes is at most nestimators 2
maxdepth
Read more in the User Guide
Parameters
nestimators integer optional default10 Number of trees in the forest
Changed in version 020 The default value of nestimators will change from 10 in version 020 to 100 in version 022
maxdepth integer optional default5 The maximum depth of each tree If None then nodes are expanded until all leaves are pure or until all leaves contain less than minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit nsamples is the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required to be at a leaf node A split point at any depth will only be considered if it leaves at least minsamplesleaf training samples in each of the left and right branches This may have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf nsamples is the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the sum total of weights of all the input samples required to be at a leaf node Samples have equal weight when sampleweight is not provided
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then unlimited number of leaf nodes

minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
sparseoutput bool optional defaultTrue Whether or not to return a sparse CSR matrix
as default behavior or to return a dense array compatible with dense pipeline operators
njobs int or None optional defaultNone The number of jobs to run in parallel for both
fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity when fitting and predicting
warmstart bool optional defaultFalse When set to True reuse the solution of the pre
vious call to fit and add more estimators to the ensemble otherwise just fit a whole new
forest See the Glossary

applyselfX
Apply trees in the forest to X return leaf indices
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
Xleaves arraylike shape nsamples nestimators For each datapoint x in X and for
each tree in the forest return the index of the leaf x ends up in
decisionpath selfX
Return the decision path in the forest
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix
where non zero elements indicates that the samples goes through the nodes
nnodesptr array of size nestimators 1 The columns from indica
tornnodesptrinnodesptri1 gives the indicator value for the ith estimator
featureimportances
Return the feature importances the higher the more important the feature
Returns
featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXyNone sampleweightNone
Fit estimator
Parameters
Xarraylike or sparse matrix shapensamples nfeatures The input samples Use
dtypenpfloat32 for maximum efficiency Sparse matrices are also supported use
sparsecscmatrix for maximum efficiency

sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
Returns
self object
fittransform selfXyNone sampleweightNone
Fit estimator and transform dataset
Parameters
Xarraylike or sparse matrix shapensamples nfeatures Input data used to build
forests Use dtypenpfloat32 for maximum efficiency
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
Returns

init selfestimators voting’hard’ weightsNone njobsNone flattentransformTrue

fitselfXysampleweightNone

Fit the estimators

Parameters

Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Note that this is supported only if all underlying estimators
support sample weights
Returns
self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get the parameters of the ensemble estimator
Parameters
deep bool Setting it to True gets the various estimators and the parameters of the estimators
as well
predictselfX
Predict class labels for X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples
Returns
maj arraylike shape nsamples Predicted class labels
predictproba
Compute probabilities of possible outcomes for samples in X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples
Returns
avg arraylike shape nsamples nclasses Weighted average probability for each class
per sample
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples

yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Setting the parameters for the ensemble estimator
Valid parameter keys can be listed with getparams
Parameters
params keyword arguments Specific parameters using eg
setparamsparameternamenewvalue In addition to setting the parameters of
the ensemble estimator the individual estimators of the ensemble estimator can also be
set or replaced by setting them to None

Table 679 – continued from previous page
transform self X Return predictions for X for each estimator
init selfestimators weightsNone njobsNone
fitselfXysampleweightNone
Fit the estimators
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Note that this is supported only if all underlying estimators
support sample weights
Returns
self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get the parameters of the ensemble estimator
Parameters
deep bool Setting it to True gets the various estimators and the parameters of the estimators
as well
predictselfX
Predict regression target for X
The predicted regression target of an input sample is computed as the mean predicted regression targets of
the estimators in the ensemble
Parameters
Xarraylike sparse matrix of shape nsamples nfeatures The input samples
Returns
yarray of shape nsamples The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score

is 10 and it can be negative because the model can be arbitrarily worse A constant model that always predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may be a precomputed kernel matrix instead shape nsamples nsamplesfitted where nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage from version 023 to keep consistent with metricsr2score This will influence the score method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses multioutputuniformaverage
setparams selfparams
Setting the parameters for the ensemble estimator
Valid parameter keys can be listed with getparams
Parameters
params keyword arguments Specific parameters using eg setparamsparameternamenewvalue In addition to setting the parameters of the ensemble estimator the individual estimators of the ensemble estimator can also be set or replaced by setting them to None
Examples
 In this example the RandomForestClassifier is removed clf1 LogisticRegression clf2 RandomForestClassifier eclf V otingClassifierestimators‘lr’ clf1 ‘rf’ clf2 eclfsetparamsrfNone
transform selfX
Return predictions for X for each estimator
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples
Returns
predictions arraylike of shape nsamples nclassifiers being values predicted by each regressor
Examples using sklearnensembleVotingRegressor
•Plot individual and voting regression predictions

Histogrambased Gradient Boosting Regression Tree
This estimator is much faster than GradientBoostingRegressor for big datasets nsamples 10 000
The input data Xis prebinned into integervalued bins which considerably reduces the number of splitting
points to consider and allows the algorithm to leverage integerbased data structures For small sample sizes
GradientBoostingRegressor might be preferred since binning may lead to split points that are too
approximate in this setting
This implementation is inspired by LightGBM
Note This estimator is still experimental for now the predictions and the API might change without any
deprecation cycle To use it you need to explicitly import enablehistgradientboosting
explicitly require this experimental feature
from sklearnexperimental import enablehistgradientboosting noqa
now you can import normally from ensemble
from sklearnensemble import HistGradientBoostingClassifier
Parameters
loss 'leastsquares' optional default'leastsquares' The loss function to use in the boost
ing process Note that the "least squares" loss actually implements an "half least squares
loss" to simplify the computation of the gradient
learningrate float optional default01 The learning rate also known as shrinkage This
is used as a multiplicative factor for the leaves values Use 1for no shrinkage
maxiter int optional default100 The maximum number of iterations of the boosting pro
cess ie the maximum number of trees
maxleafnodes int or None optional default31 The maximum number of leaves for each
tree Must be strictly greater than 1 If None there is no maximum limit
maxdepth int or None optional defaultNone The maximum depth of each tree The
depth of a tree is the number of nodes to go from the root to the deepest leaf Must be
strictly greater than 1 Depth isn't constrained by default
minsamplesleaf int optional default20 The minimum number of samples per leaf For
small datasets with less than a few hundred samples it is recommended to lower this value
since only very shallow trees would be built
l2regularization float optional default0 The L2 regularization parameter Use 0for no
regularization default

maxbins int optional default256 The maximum number of bins to use Before training each feature of the input array Xis binned into at most maxbins bins which allows for a much faster training stage Features with a small number of unique values may use less than maxbins bins Must be no larger than 256
scoring str or callable or None optional defaultNone Scoring parameter to use for early stopping It can be a single string see The scoring parameter defining model evaluation rules or a callable see Defining your scoring strategy from metric functions If None the estimator's default scorer is used If scoringloss early stopping is checked wrt the loss value Only used if niternochange is not None
validationfraction int or float or None optional default01 Proportion or absolute size of training data to set aside as validation data for early stopping If None early stopping is done on the training data Only used if niternochange is not None
niternochange int or None optional defaultNone Used to determine when to "early stop" The fitting process is stopped when none of the last niternochange scores are better than the ''niternochange 1''thtolast one up to some tolerance If None or 0 no earlystopping is done
tolfloat or None optional default1e7 The absolute tolerance to use when comparing scores during early stopping The higher the tolerance the more likely we are to early stop higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score
verbose int optional default0 The verbosity level If not zero print some information about the fitting process
randomstate int nprandomRandomStateInstance or None optional defaultNone Pseudorandom number generator to control the subsampling in the binning process and the trainvalidation data split if early stopping is enabled See randomstate
Attributes
niter int The number of iterations as selected by early stopping if niternochange is not None Otherwise it corresponds to maxiter
ntreesperiteration int The number of tree that are built at each iteration For regressors this is always 1
trainscore ndarray shape maxiter 1 The scores at each iteration on the training data The first entry is the score of the ensemble before the first iteration Scores are computed according to the scoring parameter If scoring is not 'loss' scores are computed on a subset of at most 10 000 samples Empty if no early stopping
validationscore ndarray shape maxiter 1 The scores at each iteration on the held out validation data The first entry is the score of the ensemble before the first iteration Scores are computed according to the scoring parameter Empty if no early stopping or ifvalidationfraction is None
Examples
```
To use this experimental feature we need to explicitly ask for it
from sklearnexperimental import enablehistgradientboosting  noqa
from sklearnensemble import HistGradientBoostingRegressor
from sklearndatasets import loadboston
X y  loadbostonreturnXy True
est  HistGradientBoostingRegressorfitX y
```

estscoreX y
098
Methods
fitself X y Fit the gradient boosting model
getparams self deep Get parameters for this estimator
predict self X Predict values for X
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfloss'leastsquares' learningrate01 maxiter100 maxleafnodes31

randomstateNone
fitselfXy
Fit the gradient boosting model
Parameters
Xarraylike shapensamples nfeatures The input samples
yarraylike shapensamples Target values
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict values for X
Parameters
Xarraylike shape nsamples nfeatures The input samples
Returns
yndarray shape nsamples The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00

Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object

Histogrambased Gradient Boosting Classification Tree
This estimator is much faster than GradientBoostingClassifier for big datasets nsamples 10
000 The input data Xis prebinned into integervalued bins which considerably reduces the number of splitting
points to consider and allows the algorithm to leverage integerbased data structures For small sample sizes
GradientBoostingClassifier might be preferred since binning may lead to split points that are too
approximate in this setting
This implementation is inspired by LightGBM

Note This estimator is still experimental for now the predictions and the API might change without any deprecation cycle To use it you need to explicitly import enablehistgradientboosting

```
 explicitly require this experimental feature
 from sklearnexperimental import enablehistgradientboosting  noqa
 now you can import normally from ensemble
 from sklearnensemble import HistGradientBoostingClassifier
```

Parameters

loss ‘auto’ ‘binarycrossentropy’ ‘categoricalcrossentropy’ optional default‘auto’
The loss function to use in the boosting process ‘binarycrossentropy’ also known as logistic loss is used for binary classification and generalizes to ‘categoricalcrossentropy’ for multiclass classification ‘auto’ will automatically choose either loss depending on the nature of the problem

learningrate float optional default01 The learning rate also known as shrinkage This is used as a multiplicative factor for the leaves values Use 1for no shrinkage

maxiter int optional default100 The maximum number of iterations of the boosting pro cess ie the maximum number of trees for binary classification For multiclass classifica tionnclasses trees per iteration are built

maxleafnodes int or None optional default31 The maximum number of leaves for each tree Must be strictly greater than 1 If None there is no maximum limit

maxdepth int or None optional defaultNone The maximum depth of each tree The depth of a tree is the number of nodes to go from the root to the deepest leaf Must be strictly greater than 1 Depth isn’t constrained by default

minsamplesleaf int optional default20 The minimum number of samples per leaf For small datasets with less than a few hundred samples it is recommended to lower this value since only very shallow trees would be built

l2regularization float optional default0 The L2 regularization parameter Use 0 for no regularization

maxbins int optional default256 The maximum number of bins to use Before training each feature of the input array Xis binned into at most maxbins bins which allows for a much faster training stage Features with a small number of unique values may use less than maxbins bins Must be no larger than 256

scoring str or callable or None optional defaultNone Scoring parameter to use for early stopping It can be a single string see The scoring parameter defining model evaluation rules or a callable see Defining your scoring strategy from metric functions If None the estimator’s default scorer is used If scoringloss early stopping is checked wrt the loss value Only used if niternochange is not None

validationfraction int or float or None optional default01 Proportion or absolute size of training data to set aside as validation data for early stopping If None early stopping is done on the training data

niternochange int or None optional defaultNone Used to determine when to “early stop” The fitting process is stopped when none of the last niternochange scores are better than the ‘‘niternochange 1‘‘thtolast one up to some tolerance If None or 0 no earlystopping is done

tolfloat or None optional default1e7 The absolute tolerance to use when comparing scores The higher the tolerance the more likely we are to early stop higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score
verbose int optional default0 The verbosity level If not zero print some information about the fitting process
randomstate int nprandomRandomStateInstance or None optional defaultNone Pseudorandom number generator to control the subsampling in the binning process and the trainvalidation data split if early stopping is enabled See randomstate
Attributes
niter int The number of estimators as selected by early stopping if niternochange is not None Otherwise it corresponds to maxiter
ntreesperiteration int The number of tree that are built at each iteration This is equal to 1 for binary classification and to nclasses for multiclass classification
trainscore ndarray shape maxiter 1 The scores at each iteration on the training data The first entry is the score of the ensemble before the first iteration Scores are computed according to the scoring parameter If scoring is not ‘loss’ scores are computed on a subset of at most 10 000 samples Empty if no early stopping
validationscore ndarray shape maxiter 1 The scores at each iteration on the held out validation data The first entry is the score of the ensemble before the first iteration Scores are computed according to the scoring parameter Empty if no early stopping or ifvalidationfraction is None
Examples

randomstateNone
decisionfunction selfX
Compute the decision function of X
Parameters
Xarraylike shape nsamples nfeatures The input samples
Returns
decision ndarray shape nsamples or nsamples ntreesperiteration The raw pre
dicted values ie the sum of the trees leaves for each sample ntreesperiteration is
equal to the number of classes in multiclass classification
fitselfXy
Fit the gradient boosting model
Parameters
Xarraylike shapensamples nfeatures The input samples
yarraylike shapensamples Target values
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict classes for X
Parameters
Xarraylike shape nsamples nfeatures The input samples
Returns
yndarray shape nsamples The predicted classes
predictproba selfX
Predict class probabilities for X
Parameters
Xarraylike shape nsamples nfeatures The input samples
Returns
pndarray shape nsamples nclasses The class probabilities of the input samples

scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
613sklearnexceptions Exceptions and warnings
Thesklearnexceptions module includes all custom warnings and error classes used across scikitlearn
exceptionsChangedBehaviorWarning Warning class used to notify the user of any change in the behavior
exceptionsConvergenceWarning Custom warning to capture convergence problems
exceptionsDataConversionWarning Warning used to notify implicit data conversions happening in the code
exceptionsDataDimensionalityWarning Custom warning to notify potential issues with data dimen sionality
exceptionsEfficiencyWarning Warning used to notify the user of inefficient computation
exceptionsFitFailedWarning Warning class used if there is an error while fitting the es timator
exceptionsNotFittedError Exception class to raise if estimator is used before fitting
exceptionsNonBLASDotWarning Warning used when the dot operation does not use BLAS
exceptionsUndefinedMetricWarning Warning used when the metric is invalid
6131sklearnexceptions ChangedBehaviorWarning

6133sklearnexceptions DataConversionWarning
classsklearnexceptions DataConversionWarning
Warning used to notify implicit data conversions happening in the code
This warning occurs when some input data needs to be converted or interpreted in a way that may not match the
user’s expectations
For example this warning may occur when the user
• passes an integer array to a function which expects float input and will convert the input

• requests a noncopying operation but a copy is required to meet the implementation’s datatype ex
pectations
• passes an input whose shape can be interpreted ambiguously

614sklearnexperimental Experimental
Thesklearnexperimental module provides importable modules that enable the use of experimental features
or estimators
The features and estimators that are experimental aren’t subject to deprecation cycles Use them at your own risks
experimentalenablehistgradientboosting Enables histogrambased gradient boosting estimators
experimentalenableiterativeimputer Enables IterativeImputer
6141 sklearnexperimentalenablehistgradientboosting
Enables histogrambased gradient boosting estimators
The API and results of these estimators might change without any deprecation cycle
Importing this file dynamically sets the sklearnensembleHistGradientBoostingClassifier and
sklearnensembleHistGradientBoostingRegressor as attributes of the ensemble module
```
 explicitly require this experimental feature
 from sklearnexperimental import enablehistgradientboosting  noqa
 now you can import normally from ensemble
```

```
 from sklearnensemble import HistGradientBoostingClassifier
 from sklearnensemble import HistGradientBoostingRegressor
```
The noqa comment comment can be removed it just tells linters like flake8 to ignore the import which appears as unused

6142 sklearnexperimentalenableiterativeimputer

Enables IterativeImputer

The API and results of this estimator might change without any deprecation cycle

Importing this file dynamically sets sklearnimputeIterativeImputer as an attribute of the impute mod ule

```
 explicitly require this experimental feature
 from sklearnexperimental import enableiterativeimputer  noqa
 now you can import normally from impute
 from sklearnimpute import IterativeImputer
```

615sklearnfeatureextraction Feature Extraction

Thesklearnfeatureextraction module deals with feature extraction from raw data It currently includes methods to extract features from text and images

User guide See the Feature extraction section for further details

featureextractionDictVectorizer dtype
   Transforms lists of featurevalue mappings to vectors

featureextractionFeatureHasher   Implements feature hashing aka the hashing trick

6151sklearnfeatureextraction DictVectorizer

classsklearnfeatureextraction DictVectorizer dtypeclass ‘numpyfloat64’ separa tor’’ sparseTrue sortTrue

Transforms lists of featurevalue mappings to vectors

This transformer turns lists of mappings dictlike objects of feature names to feature values into Numpy arrays or scipysparse matrices for use with scikitlearn estimators

When feature values are strings this transformer will do a binary onehot aka oneofK coding one boolean valued feature is constructed for each of the possible string values that the feature can take on For instance a feature “f” that can take on the values “ham” and “spam” will become two features in the output one signifying “fham” the other “fspam”

However note that this transformer will only do a binary onehot encoding when feature values are of type string If categorical features are represented as numeric values such as int the DictVectorizer can be followed bysklearnpreprocessingOneHotEncoder to complete binary onehot encoding

Features that do not occur in a sample mapping will have a zero value in the resulting arraymatrix

Read more in the User Guide

Parameters

dtype callable optional The type of feature values Passed to Numpy arrayscipysparse ma
trix constructors as the dtype argument
separator string optional Separator string used when constructing new features for onehot
coding
sparse boolean optional Whether transform should produce scipysparse matrices True by
default
sort boolean optional Whether featurenames andvocabulary should be sorted
when fitting True by default
Attributes
vocabulary dict A dictionary mapping feature names to feature indices
featurenames list A list of length nfeatures containing the feature names eg “fham”
and “fspam”
See also
FeatureHasher performs vectorization using only a hash function
sklearnpreprocessingOrdinalEncoder handles nominalcategorical features encoded as
columns of arbitrary data types
Examples
```
 from sklearnfeatureextraction import DictVectorizer
v  DictVectorizersparse False
D  foo 1 bar 2 foo 3 baz 1
X  vfittransformD
X
array2 0 1
0 1 3
vinversetransformX  bar 20 foo 10 baz 10 foo
‘→ 30
True
vtransformfoo 4 unseenfeature 3
array0 0 4
```
Methods
fitself X y Learn a list of feature name indices mappings
fittransform self X y Learn a list of feature name indices mappings and
transform X
getfeaturenames self Returns a list of feature names ordered by their indices
getparams self deep Get parameters for this estimator
inversetransform self X dicttype Transform array or sparse matrix X back to feature map
pings
restrict self support indices Restrict the features to those in support using feature
selection
setparams self params Set the parameters of this estimator

transform self X Transform featurevalue dicts to array or sparse ma
trix
init selfdtypeclass ‘numpyfloat64’ separator’’ sparseTrue sortTrue
fitselfXyNone
Learn a list of feature name indices mappings
Parameters
XMapping or iterable over Mappings Dicts or Mappings from feature names arbitrary
Python objects to feature values strings or convertible to dtype
yignored
Returns
self
fittransform selfXyNone
Learn a list of feature name indices mappings and transform X
Like fitX followed by transformX but does not require materializing X in memory
Parameters
XMapping or iterable over Mappings Dicts or Mappings from feature names arbitrary
Python objects to feature values strings or convertible to dtype
yignored
Returns
Xaarray sparse matrix Feature vectors always 2d
getfeaturenames self
Returns a list of feature names ordered by their indices
If oneofK coding is applied to categorical features this will include the constructed feature names but
not the original ones
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfXdicttypeclass ‘dict’
Transform array or sparse matrix X back to feature mappings
X must have been produced by this DictVectorizer’s transform or fittransform method it may only have
passed through transformers that preserve the number of features and their order
In the case of onehotoneofK coding the constructed feature names and values are returned rather than
the original ones
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Sample matrix

scikitlearn user guide Release 0213
dicttype callable optional Constructor for feature mappings Must conform to the col
lectionsMapping API
Returns
Dlist of dicttype objects length nsamples Feature mappings for the samples in X
restrict selfsupport indicesFalse
Restrict the features to those in support using feature selection
This function modifies the estimator inplace
Parameters
support arraylike Boolean mask or list of indices as returned by the getsupport member
of feature selectors
indices boolean optional Whether support is a list of indices
Returns
self
Examples
 from sklearnfeatureextraction import DictVectorizer
 from sklearnfeatureselection import SelectKBest chi2

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform featurevalue dicts to array or sparse matrix
Named features not encountered during fit or fittransform will be silently ignored
Parameters
XMapping or iterable over Mappings length nsamples Dicts or Mappings from
feature names arbitrary Python objects to feature values strings or convertible to dtype
Returns

Xaarray sparse matrix Feature vectors always 2d
Examples using sklearnfeatureextractionDictVectorizer
•Column Transformer with Heterogeneous Data Sources
•FeatureHasher and DictVectorizer Comparison
6152sklearnfeatureextraction FeatureHasher
classsklearnfeatureextraction FeatureHasher nfeatures1048576 inputtype’dict’
dtypeclass ‘numpyfloat64’ alter
natesignTrue
Implements feature hashing aka the hashing trick
This class turns sequences of symbolic feature names strings into scipysparse matrices using a hash function to compute the matrix column corresponding to a name The hash function employed is the signed 32bit version of Murmurhash3
Feature names of type byte string are used asis Unicode strings are converted to UTF8 first but no Unicode normalization is done Feature values must be finite numbers
This class is a lowmemory alternative to DictVectorizer and CountVectorizer intended for largescale online learning and situations where memory is tight eg when running prediction code on embedded devices
Read more in the User Guide
Parameters
nfeatures integer optional The number of features columns in the output matrices Small numbers of features are likely to cause hash collisions but large numbers will cause larger coefficient dimensions in linear learners
inputtype string optional default “dict” Either “dict” the default to accept dictionaries over featurename value “pair” to accept pairs of featurename value or “string” to accept single strings featurename should be a string while value should be a number In the case of “string” a value of 1 is implied The featurename is hashed to find the appropriate column for the feature The value’s sign might be flipped in the output but see nonnegative below
dtype numpy type optional default npfloat64 The type of feature values Passed to scipysparse matrix constructors as the dtype argument Do not set this to bool npboolean or any unsigned integer type
alternatesign boolean optional default True When True an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small nfeatures This approach is similar to sparse random projection
See also
DictVectorizer vectorizes stringvalued features using a hash table
sklearnpreprocessingOneHotEncoder handles nominalcategorical features

Examples
```
 from sklearnfeatureextraction import FeatureHasher
h  FeatureHashernfeatures10
D  dog 1 cat2 elephant4dog 2 run 5
f  htransformD
ftoarray
array 0 0 4 1 0 0 0 0 0 2
 0 0 0 2 5 0 0 0 0 0
```
Methods
fitself X y Noop
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator
transform self rawX Transform a sequence of instances to a scipysparse ma
trix
init selfnfeatures1048576 inputtype’dict’ dtypeclass ‘numpyfloat64’ alter
natesignTrue
fitselfXNone yNone
Noop
This method doesn’t do anything It exists purely for compatibility with the scikitlearn transformer API
Parameters
Xarraylike
Returns
self FeatureHasher
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns

params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfrawX
Transform a sequence of instances to a scipysparse matrix
Parameters
rawX iterable over iterable over raw features length nsamples Samples Each sample
must be iterable an eg a list or tuple containinggenerating feature names and option
ally values see the inputtype constructor argument which will be hashed rawX need
not support the len function so it can be the result of a generator nsamples is determined
on the fly
Returns
Xscipysparse matrix shape nsamples selfnfeatures Feature matrix for use with
estimators or further transformers
Examples using sklearnfeatureextractionFeatureHasher

Reshape a 2D image into a collection of patches
The resulting patches are allocated in a dedicated array

scikitlearn user guide Release 0213
Read more in the User Guide
Parameters
image array shape imageheight imagewidth or imageheight imagewidth
nchannels The original image data For color images the last dimension specifies the
channel a RGB image would have nchannels3
patchsize tuple of ints patchheight patchwidth the dimensions of one patch
maxpatches integer or float optional default is None The maximum number of patches to
extract If maxpatches is a float between 0 and 1 it is taken to be a proportion of the total
number of patches
randomstate int RandomState instance or None optional defaultNone Pseudo number
generator state used for random sampling to use if maxpatches is not None If int
randomstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is the
RandomState instance used by nprandom
Returns
patches array shape npatches patchheight patchwidth or npatches patchheight
patchwidth nchannels The collection of patches extracted from the image where
npatches is eithermaxpatches or the total number of patches that can be extracted
Examples
 from sklearndatasets import loadsampleimage
 from sklearnfeatureextraction import image
 Use the array data from the first image in this dataset
oneimage loadsampleimagechinajpg
printImage shape formatoneimageshape

615sklearnfeatureextraction Feature Extraction 1743

sklearnfeatureextractionimage gridtograph
sklearnfeatureextractionimage gridtograph nx ny nz1
maskNone returnasclass
‘scipysparsecoocoomatrix’
dtypeclass ‘int’
Graph of the pixeltopixel connections
Edges exist if 2 voxels are connected
Parameters
nx int Dimension in x axis
ny int Dimension in y axis
nz int optional default 1 Dimension in z axis
mask ndarray of booleans optional An optional mask of the image to consider only part of
the pixels
returnas npndarray or a sparse matrix class optional The class to use to build the returned
adjacency matrix
dtype dtype optional default int The data of the returned sparse matrix By default it is int
Notes
For scikitlearn versions 0141 and prior returnasnpndarray was handled by returning a dense npmatrix
instance Going forward npndarray returns an npndarray as expected
For compatibility user code relying on this method should wrap its calls in npasarray to avoid type issues
sklearnfeatureextractionimage imgtograph
sklearnfeatureextractionimage imgtograph imgmaskNone returnasclass
‘scipysparsecoocoomatrix’
dtypeNone
Graph of the pixeltopixel gradient connections
Edges are weighted with the gradient values
Read more in the User Guide
Parameters
img ndarray 2D or 3D 2D or 3D image
mask ndarray of booleans optional An optional mask of the image to consider only part of
the pixels
returnas npndarray or a sparse matrix class optional The class to use to build the returned
adjacency matrix
dtype None or dtype optional The data of the returned sparse matrix By default it is the
dtype of img

Notes
For scikitlearn versions 0141 and prior returnasnpndarray was handled by returning a dense npmatrix instance Going forward npndarray returns an npndarray as expected
For compatibility user code relying on this method should wrap its calls in npasarray to avoid type issues
sklearnfeatureextractionimage reconstructfrompatches2d
sklearnfeatureextractionimage reconstructfrompatches2d patches im agesize
Reconstruct the image from all of its patches
Patches are assumed to overlap and the image is constructed by filling in the patches from left to right top to bottom averaging the overlapping regions
Read more in the User Guide
Parameters
patches array shape npatches patchheight patchwidth or npatches patchheight patchwidth nchannels The complete set of patches If the patches contain colour information channels are indexed along the last dimension RGB patches would have nchannels3
imagesize tuple of ints imageheight imagewidth or imageheight imagewidth nchannels the size of the image that will be reconstructed
Returns
image array shape imagesize the reconstructed image
Examples using sklearnfeatureextractionimagereconstructfrompatches2d
•Image denoising using dictionary learning
sklearnfeatureextractionimage PatchExtractor
classsklearnfeatureextractionimage PatchExtractor patchsizeNone maxpatchesNone ran domstateNone
Extracts patches from a collection of images
Read more in the User Guide
Parameters
patchsize tuple of ints patchheight patchwidth the dimensions of one patch
maxpatches integer or float optional default is None The maximum number of patches per image to extract If maxpatches is a float in 0 1 it is taken to mean a proportion of the total number of patches
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom

Examples
```
 from sklearndatasets import loadsampleimages
 from sklearnfeatureextraction import image
 Use the array data from the second image in this dataset
X  loadsampleimagesimages1
printImage shape formatXshape
Image shape 427 640 3
pe  imagePatchExtractorpatchsize2 2
pefit  pefitX
petrans  petransformX
printPatches shape formatpetransshape
Patches shape 545706 2 2
```
Methods
fitself X y Do nothing and return the estimator unchanged
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator
transform self X Transforms the image samples in X into a matrix of
patch data
```
init selfpatchsizeNone maxpatchesNone randomstateNone
```
fitselfXyNone
Do nothing and return the estimator unchanged
This method is just there to implement the usual API and hence work in pipelines
Parameters
Xarraylike shape nsamples nfeatures Training data
```
getparams selfdeepTrue
```
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
```
setparams selfparams
```
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
```
transform selfX
```
Transforms the image samples in X into a matrix of patch data

Parameters
Xarray shape nsamples imageheight imagewidth or nsamples imageheight
imagewidth nchannels Array of images from which to extract patches For
color images the last dimension specifies the channel a RGB image would have
nchannels3
Returns
patches array shape npatches patchheight patchwidth or npatches
patchheight patchwidth nchannels The collection of patches extracted from the im
ages where npatches is eithernsamples maxpatches or the total number
of patches that can be extracted

stopwordsNone to
kenpattern’ubwwb’
ngramrange1 1 ana
lyzer’word’ maxdf10
mindf1 maxfeaturesNone
vocabularyNone binaryFalse
dtypeclass ‘numpyint64’
Convert a collection of text documents to a matrix of token counts
This implementation produces a sparse representation of the counts using scipysparsecsrmatrix
If you do not provide an apriori dictionary and you do not use an analyzer that does some kind of feature
selection then the number of features will be equal to the vocabulary size found by analyzing the data
Read more in the User Guide
Parameters
input string ‘filename’ ‘file’ ‘content’ If ‘filename’ the sequence passed as an argument to
fit is expected to be a list of filenames that need reading to fetch the raw content to analyze

If ‘file’ the sequence items must have a ‘read’ method filelike object that is called to fetch the bytes in memory
Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly
encoding string ‘utf8’ by default If bytes or files are given to analyze this encoding is used to decode
decodeerror ‘strict’ ‘ignore’ ‘replace’ Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding By default it is ‘strict’ meaning that a UnicodeDecodeError will be raised Other values are ‘ignore’ and ‘replace’
stripaccents ‘ascii’ ‘unicode’ None Remove accents and perform other character nor malization during the preprocessing step ‘ascii’ is a fast method that only works on char acters that have an direct ASCII mapping ‘unicode’ is a slightly slower method that works on any characters None default does nothing
Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicodedatanormalize
lowercase boolean True by default Convert all characters to lowercase before tokenizing
preprocessor callable or None default Override the preprocessing string transformation stage while preserving the tokenizing and ngrams generation steps
tokenizer callable or None default Override the string tokenization step while preserving the preprocessing and ngrams generation steps Only applies if analyzer word
stopwords string ‘english’ list or None default If ‘english’ a builtin stop word list for English is used There are several known issues with ‘english’ and you should consider an alternative see Using stop words
If a list that list is assumed to contain stop words all of which will be removed from the resulting tokens Only applies if analyzer word
If None no stop words will be used maxdf can be set to a value in the range 07 10 to automatically detect and filter stop words based on intra corpus document frequency of terms
tokenpattern string Regular expression denoting what constitutes a “token” only used if analyzer word The default regexp select tokens of 2 or more alphanumeric characters punctuation is completely ignored and always treated as a token separator
ngramrange tuple minn maxn The lower and upper boundary of the range of nvalues for different ngrams to be extracted All values of n such that minn n maxn will be used
analyzer string ‘word’ ‘char’ ‘charwb’ or callable Whether the feature should be made of word or character ngrams Option ‘charwb’ creates character ngrams only from text inside word boundaries ngrams at the edges of words are padded with space
If a callable is passed it is used to extract the sequence of features out of the raw unprocessed input
Changed in version 021
Since v021 if input isfilename orfile the data is first read from the file and then passed to the given callable analyzer
maxdf float in range 00 10 or int default10 When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold corpusspecific stop

words If float the parameter represents a proportion of documents integer absolute counts
This parameter is ignored if vocabulary is not None
mindf float in range 00 10 or int default1 When building the vocabulary ignore terms
that have a document frequency strictly lower than the given threshold This value is also
called cutoff in the literature If float the parameter represents a proportion of documents
integer absolute counts This parameter is ignored if vocabulary is not None
maxfeatures int or None defaultNone If not None build a vocabulary that only consider
the top maxfeatures ordered by term frequency across the corpus
This parameter is ignored if vocabulary is not None
vocabulary Mapping or iterable optional Either a Mapping eg a dict where keys are terms
and values are indices in the feature matrix or an iterable over terms If not given a vocabu
lary is determined from the input documents Indices in the mapping should not be repeated
and should not have any gap between 0 and the largest index
binary boolean defaultFalse If True all non zero counts are set to 1 This is useful for
discrete probabilistic models that model binary events rather than integer counts
dtype type optional Type of the matrix returned by fittransform or transform
Attributes
vocabulary dict A mapping of terms to feature indices
stopwords set Terms that were ignored because they either
• occurred in too many documents maxdf
• occurred in too few documents mindf
• were cut off by feature selection maxfeatures
This is only available if no vocabulary was given
See also

buildanalyzer self
Return a callable that handles preprocessing and tokenization
buildpreprocessor self
Return a function to preprocess the text before tokenization
buildtokenizer self
Return a function that splits a string into a sequence of tokens
decodeselfdoc
Decode the input into a string of unicode symbols
The decoding strategy depends on the vectorizer parameters
Parameters
doc string The string to decode
fitselfrawdocuments yNone
Learn a vocabulary dictionary of all tokens in the raw documents
Parameters

rawdocuments iterable An iterable which yields either str unicode or file objects
Returns
self
fittransform selfrawdocuments yNone
Learn the vocabulary dictionary and return termdocument matrix
This is equivalent to fit followed by transform but more efficiently implemented
Parameters
rawdocuments iterable An iterable which yields either str unicode or file objects
Returns
Xarray nsamples nfeatures Documentterm matrix
getfeaturenames self
Array mapping from feature integer indices to feature name
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getstopwords self
Build or fetch the effective stop words list
inversetransform selfX
Return terms per document with nonzero entries in X
Parameters
Xarray sparse matrix shape nsamples nfeatures
Returns
Xinv list of arrays len nsamples List of arrays of terms
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfrawdocuments
Transform documents to documentterm matrix
Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to
the constructor
Parameters
rawdocuments iterable An iterable which yields either str unicode or file objects

Returns
Xsparse matrix nsamples nfeatures Documentterm matrix

naryFalse norm’l2’
alternatesignTrue
dtypeclass
‘numpyfloat64’
Convert a collection of text documents to a matrix of token occurrences
It turns a collection of text documents into a scipysparse matrix holding token occurrence counts or binary occurrence information possibly normalized as token frequencies if norm’l1’ or projected on the euclidean unit sphere if norm’l2’
This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping
This strategy has several advantages
• it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
• it is fast to pickle and unpickle as it holds no state besides the constructor parameters
• it can be used in a streaming partial fit or parallel pipeline as there is no state computed during fit
There are also a couple of cons vs using a CountVectorizer with an inmemory vocabulary
• there is no way to compute the inverse transform from feature indices to string feature names which can be a problem when trying to introspect which features are most important to a model
• there can be collisions distinct tokens can be mapped to the same feature index However in practice this is rarely an issue if nfeatures is large enough eg 2 18 for text classification problems
• no IDF weighting as this would render the transformer stateful
The hash function employed is the signed 32bit version of Murmurhash3

Parameters

scikitlearn user guide Release 0213
input string ‘filename’ ‘file’ ‘content’ If ‘filename’ the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze If ‘file’ the sequence items must have a ‘read’ method filelike object that is called to fetch the bytes in memory
Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly
encoding string default’utf8’ If bytes or files are given to analyze this encoding is used to decode
decodeerror ‘strict’ ‘ignore’ ‘replace’ Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding By default it is ‘strict’ meaning that a UnicodeDecodeError will be raised Other values are ‘ignore’ and ‘replace’
stripaccents ‘ascii’ ‘unicode’ None Remove accents and perform other character nor malization during the preprocessing step ‘ascii’ is a fast method that only works on char acters that have an direct ASCII mapping ‘unicode’ is a slightly slower method that works on any characters None default does nothing
Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicodedatanormalize
lowercase boolean defaultTrue Convert all characters to lowercase before tokenizing
preprocessor callable or None default Override the preprocessing string transformation stage while preserving the tokenizing and ngrams generation steps
tokenizer callable or None default Override the string tokenization step while preserving the preprocessing and ngrams generation steps Only applies if analyzer word
stopwords string ‘english’ list or None default If ‘english’ a builtin stop word list for English is used There are several known issues with ‘english’ and you should consider an alternative see Using stop words
If a list that list is assumed to contain stop words all of which will be removed from the resulting tokens Only applies if analyzer word
tokenpattern string Regular expression denoting what constitutes a “token” only used if analyzer word The default regexp selects tokens of 2 or more alphanumeric characters punctuation is completely ignored and always treated as a token separator
ngramrange tuple minn maxn default1 1 The lower and upper boundary of the range of nvalues for different ngrams to be extracted All values of n such that minn n maxn will be used
analyzer string ‘word’ ‘char’ ‘charwb’ or callable Whether the feature should be made of word or character ngrams Option ‘charwb’ creates character ngrams only from text inside word boundaries ngrams at the edges of words are padded with space
If a callable is passed it is used to extract the sequence of features out of the raw unprocessed input
Changed in version 021
Since v021 if input isfilename orfile the data is first read from the file and then passed to the given callable analyzer
nfeatures integer default2 20 The number of features columns in the output matri ces Small numbers of features are likely to cause hash collisions but large numbers will cause larger coefficient dimensions in linear learners
615sklearnfeatureextraction Feature Extraction 1753

binary boolean defaultFalse If True all non zero counts are set to 1 This is useful for
discrete probabilistic models that model binary events rather than integer counts
norm ‘l1’ ‘l2’ or None optional Norm used to normalize term vectors None for no normal
ization
alternatesign boolean optional default True When True an alternating sign is added to the
features as to approximately conserve the inner product in the hashed space even for small
nfeatures This approach is similar to sparse random projection
New in version 019
dtype type optional Type of the matrix returned by fittransform or transform

Examples using sklearnfeatureextractiontextHashingVectorizer
•Outofcore classification of text documents
•Clustering text documents using kmeans
•Classification of text documents using sparse features
sklearnfeatureextractiontext TfidfTransformer
classsklearnfeatureextractiontext TfidfTransformer norm’l2’ useidfTrue smoothidfTrue sublin eartfFalse
Transform a count matrix to a normalized tf or tfidf representation
Tf means termfrequency while tfidf means termfrequency times inverse documentfrequency This is a common term weighting scheme in information retrieval that has also found good use in document classification
The goal of using tfidf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus
The formula that is used to compute the tfidf for a term t of a document d in a document set is tfidft d tft d idft and the idf is computed as idft log n dft 1 if smoothidfFalse where n is the total number of documents in the document set and dft is the document frequency of t the document frequency is the number of documents in the document set that contain the term t The effect of adding “1” to the idf in the equation above is that terms with zero idf ie terms that occur in all documents in a training set will not be entirely ignored Note that the idf formula above differs from the standard textbook notation that defines the idf as idft log n dft 1
IfsmoothidfTrue the default the constant “1” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once which prevents zero divisions idfd t log 1 n 1 dfd t 1

Furthermore the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows
Tf is “n” natural by default “l” logarithmic when sublineartfTrue Idf is “t” when useidf is given “n” none otherwise Normalization is “c” cosine when norml2 “n” none when normNone
Read more in the User Guide
Parameters
norm ‘l1’ ‘l2’ or None optional default’l2’ Each output row will have unit norm either ‘l2’ Sum of squares of vector elements is 1 The cosine similarity between two vectors is their dot product when l2 norm has been applied ‘l1’ Sum of absolute values of vector elements is 1 See preprocessingnormalize
useidf boolean defaultTrue Enable inversedocumentfrequency reweighting
smoothidf boolean defaultTrue Smooth idf weights by adding one to document frequencies as if an extra document was seen containing every term in the collection exactly once Prevents zero divisions
sublineartf boolean defaultFalse Apply sublinear tf scaling ie replace tf with 1 logtf
Attributes
idf array shape nfeatures The inverse document frequency IDF vector only defined if useidf is True

If None no stop words will be used maxdf can be set to a value in the range 07 10 to automatically detect and filter stop words based on intra corpus document frequency of terms
tokenpattern string Regular expression denoting what constitutes a “token” only used if analyzer word The default regexp selects tokens of 2 or more alphanumeric characters punctuation is completely ignored and always treated as a token separator
ngramrange tuple minn maxn default1 1 The lower and upper boundary of the range of nvalues for different ngrams to be extracted All values of n such that minn n maxn will be used
maxdf float in range 00 10 or int default10 When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold corpus specific stop words If float the parameter represents a proportion of documents integer absolute counts This parameter is ignored if vocabulary is not None
mindf float in range 00 10 or int default1 When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold This value is also called cutoff in the literature If float the parameter represents a proportion of documents integer absolute counts This parameter is ignored if vocabulary is not None
maxfeatures int or None defaultNone If not None build a vocabulary that only consider the top maxfeatures ordered by term frequency across the corpus
This parameter is ignored if vocabulary is not None
vocabulary Mapping or iterable optional defaultNone Either a Mapping eg a dict where keys are terms and values are indices in the feature matrix or an iterable over terms If not given a vocabulary is determined from the input documents
binary boolean defaultFalse If True all nonzero term counts are set to 1 This does not mean outputs will have only 01 values only that the tf term in tfidf is binary Set idf and normalization to False to get 01 outputs
dtype type optional defaultfloat64 Type of the matrix returned by fittransform or transform
norm ‘l1’ ‘l2’ or None optional default’l2’ Each output row will have unit norm either ‘l2’ Sum of squares of vector elements is 1 The cosine similarity between two vectors is their dot product when l2 norm has been applied ‘l1’ Sum of absolute values of vector elements is 1 See preprocessingnormalize
useidf boolean defaultTrue Enable inversedocumentfrequency reweighting

smoothidf boolean defaultTrue Smooth idf weights by adding one to document frequen
cies as if an extra document was seen containing every term in the collection exactly once
Prevents zero divisions
sublineartf boolean defaultFalse Apply sublinear tf scaling ie replace tf with 1
logtf
Attributes
vocabulary dict A mapping of terms to feature indices
idf array shape nfeatures The inverse document frequency IDF vector only defined if
useidf is True
stopwords set Terms that were ignored because they either
• occurred in too many documents maxdf
• occurred in too few documents mindf
• were cut off by feature selection maxfeatures
This is only available if no vocabulary was given
See also
CountVectorizer Transforms text into a sparse matrix of ngram counts
TfidfTransformer Performs the TFIDF transformation from a provided matrix of counts
Notes
Thestopwords attribute can get large and increase the model size when pickling This attribute is provided
only for introspection and can be safely removed using delattr or set to None before pickling
Examples
 from sklearnfeatureextractiontext import TfidfVectorizer
corpus
 This is the first document
 This document is the second document
 And this is the third one
 Is this the first document

vectorizer TfidfVectorizer
X vectorizerfittransformcorpus
printvectorizergetfeaturenames
and document first is one second the third this
printXshape
4 9
Methods
buildanalyzer self Return a callable that handles preprocessing and tok
enization
Continued on next page

Table 6103 – continued from previous page

buildpreprocessor self	Return a function to preprocess the text before tokeniza tion
buildtokenizer self	Return a function that splits a string into a sequence of tokens
decode self doc	Decode the input into a string of unicode symbols
fitself rawdocuments y	Learn vocabulary and idf from training set
fittransform self rawdocuments y	Learn vocabulary and idf return termdocument matrix
getfeaturenames self	Array mapping from feature integer indices to feature name
getparams self deep	Get parameters for this estimator
getstopwords self	Build or fetch the effective stop words list
inversetransform self X	Return terms per document with nonzero entries in X
setparams self params	Set the parameters of this estimator
transform self rawdocuments copy	Transform documents to documentterm matrix

init selfinput'content' encoding'utf8' decodeerror'strict' stripaccentsNone low ercaseTrue preprocessorNone tokenizerNone analyzer'word' stopwordsNone tokenpattern'ubwwb' ngramrange1 1maxdf10 mindf1 maxfeaturesNone vocabularyNone binaryFalse dtypeclass 'numpyfloat64' norm'l2' useidfTrue smoothidfTrue sublineartfFalse

buildanalyzer self

Return a callable that handles preprocessing and tokenization

buildpreprocessor self

Return a function to preprocess the text before tokenization

buildtokenizer self

Return a function that splits a string into a sequence of tokens

decodeselfdoc

Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters

Parameters

doc string The string to decode

fitselfrawdocuments yNone

Learn vocabulary and idf from training set

Parameters

rawdocuments iterable an iterable which yields either str unicode or file objects

Returns

self TfidfVectorizer

fittransform selfrawdocuments yNone

Learn vocabulary and idf return termdocument matrix

This is equivalent to fit followed by transform but more efficiently implemented

Parameters

rawdocuments iterable an iterable which yields either str unicode or file objects

Returns

Xsparse matrix nsamples nfeatures Tfidfweighted documentterm matrix

getfeaturenames self
Array mapping from feature integer indices to feature name
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getstopwords self
Build or fetch the effective stop words list
inversetransform selfX
Return terms per document with nonzero entries in X
Parameters
Xarray sparse matrix shape nsamples nfeatures
Returns
Xinv list of arrays len nsamples List of arrays of terms
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfrawdocuments copyTrue
Transform documents to documentterm matrix
Uses the vocabulary and document frequencies df learned by fit or fittransform
Parameters
rawdocuments iterable an iterable which yields either str unicode or file objects
copy boolean default True Whether to copy X and operate on the copy or perform inplace
operations
Returns
Xsparse matrix nsamples nfeatures Tfidfweighted documentterm matrix
Examples using sklearnfeatureextractiontextTfidfVectorizer
•Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet Allocation
•Biclustering documents with the Spectral Coclustering algorithm
•Column Transformer with Heterogeneous Data Sources
•Clustering text documents using kmeans

•Classification of text documents using sparse features
616sklearnfeatureselection Feature Selection
Thesklearnfeatureselection module implements feature selection algorithms It currently includes uni
variate filter selection methods and the recursive feature elimination algorithm
User guide See the Feature selection section for further details
featureselection
GenericUnivariateSelect Univariate feature selector with configurable strategy
featureselectionSelectPercentile Select features according to a percentile of the highest
scores
featureselectionSelectKBest scorefunc
kSelect features according to the k highest scores
featureselectionSelectFpr scorefunc al
phaFilter Select the pvalues below alpha based on a FPR test
featureselectionSelectFdr scorefunc al
phaFilter Select the pvalues for an estimated false discovery
rate
featureselection
SelectFromModel estimatorMetatransformer for selecting features based on impor
tance weights
featureselectionSelectFwe scorefunc al
phaFilter Select the pvalues corresponding to Familywise
error rate
featureselectionRFE estimator Feature ranking with recursive feature elimination
featureselectionRFECV estimator step Feature ranking with recursive feature elimination and
crossvalidated selection of the best number of features
featureselection
VarianceThreshold thresholdFeature selector that removes all lowvariance features
6161sklearnfeatureselection GenericUnivariateSelect
classsklearnfeatureselection GenericUnivariateSelect scorefuncfunction
fclassif mode’percentile’
param1e05
Univariate feature selector with configurable strategy
Read more in the User Guide
Parameters
scorefunc callable Function taking two arrays X and y and returning a pair of arrays scores
pvalues For modes ‘percentile’ or ‘kbest’ it can return a single array scores
mode ‘percentile’ ‘kbest’ ‘fpr’ ‘fdr’ ‘fwe’ Feature selection mode
param float or int depending on the feature selection mode Parameter of the corresponding
mode
Attributes
scores arraylike shapenfeatures Scores of features
pvalues arraylike shapenfeatures pvalues of feature scores None if scorefunc
returned scores only

SelectPercentile Select features based on percentile of the highest scores
SelectKBest Select features based on the k highest scores
SelectFpr Select features based on a false positive rate test
SelectFdr Select features based on an estimated false discovery rate
SelectFwe Select features based on familywise error rate
Examples
```
 from sklearndatasets import loadbreastcancer
 from sklearnfeatureselection import GenericUnivariateSelect chi2
X y  loadbreastcancerreturnXy True
Xshape
569 30
transformer  GenericUnivariateSelectchi2 kbest param20
Xnew  transformerfittransformX y
Xnewshape
569 20
```
Methods
fitself X y Run score function on X y and get the appropriate
features
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
getsupport self indices Get a mask or integer index of the features selected
inversetransform self X Reverse the transformation operation
setparams self params Set the parameters of this estimator
transform self X Reduce X to the selected features
init selfscorefuncfunction fclassif at 0x7efe30bb2158 mode’percentile’ param1e
05
fitselfXy
Run score function on X y and get the appropriate features
Parameters
Xarraylike shape nsamples nfeatures The training input samples
yarraylike shape nsamples The target values class labels in classification real num
bers in regression
Returns

self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
6162sklearnfeatureselection SelectPercentile
classsklearnfeatureselection SelectPercentile scorefuncfunction fclassif per
centile10
Select features according to a percentile of the highest scores
Read more in the User Guide
Parameters
scorefunc callable Function taking two arrays X and y and returning a pair of arrays scores
pvalues or a single array with scores Default is fclassif see below “See also” The
default function only works with classification tasks
percentile int optional default10 Percent of features to keep
Attributes
scores arraylike shapenfeatures Scores of features
pvalues arraylike shapenfeatures pvalues of feature scores None if scorefunc
returned only scores
See also
fclassif ANOV A Fvalue between labelfeature for classification tasks

SelectKBest Select features based on the k highest scores
SelectFpr Select features based on a false positive rate test
SelectFdr Select features based on an estimated false discovery rate
SelectFwe Select features based on familywise error rate
GenericUnivariateSelect Univariate feature selector with configurable mode
Notes
Ties between features with equal scores will be broken in an unspecified way

Examples
```
 from sklearndatasets import loaddigits
 from sklearnfeatureselection import SelectPercentile chi2
X y  loaddigitsreturnXy True
Xshape
1797 64
Xnew  SelectPercentilechi2 percentile10fittransformX y
Xnewshape
1797 7
```
Methods
fitself X y Run score function on X y and get the appropriate
features
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
getsupport self indices Get a mask or integer index of the features selected
inversetransform self X Reverse the transformation operation
setparams self params Set the parameters of this estimator
transform self X Reduce X to the selected features
init selfscorefuncfunction fclassif at 0x7f3c10e93840 percentile10
fitselfXy
Run score function on X y and get the appropriate features
Parameters
Xarraylike shape nsamples nfeatures The training input samples
yarraylike shape nsamples The target values class labels in classification real num
bers in regression
Returns
self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
Examples using sklearnfeatureselectionSelectPercentile
•Feature agglomeration vs univariate selection
•Univariate Feature Selection
•SVMAnova SVM with univariate feature selection

scikitlearn user guide Release 0213
6163sklearnfeatureselection SelectKBest
classsklearnfeatureselection SelectKBest scorefuncfunction fclassif k10
Select features according to the k highest scores
Read more in the User Guide
Parameters
scorefunc callable Function taking two arrays X and y and returning a pair of arrays scores
pvalues or a single array with scores Default is fclassif see below “See also” The
default function only works with classification tasks
kint or “all” optional default10 Number of top features to select The “all” option bypasses
selection for use in a parameter search
Attributes
scores arraylike shapenfeatures Scores of features
pvalues arraylike shapenfeatures pvalues of feature scores None if scorefunc
returned only scores

fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set

ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns

Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
6166sklearnfeatureselection SelectFromModel
classsklearnfeatureselection SelectFromModel estimator thresholdNone prefitFalse
normorder1 maxfeaturesNone
Metatransformer for selecting features based on importance weights
New in version 017
Parameters
estimator object The base estimator from which the transformer is built This can be both a
fitted ifprefit is set to True or a nonfitted estimator The estimator must have either a
featureimportances orcoef attribute after fitting
threshold string float optional default None The threshold value to use for feature selection
Features whose importance is greater or equal are kept while the others are discarded If
“median” resp “mean” then the threshold value is the median resp the mean of the
feature importances A scaling factor eg “125mean” may also be used If None and
if the estimator has a parameter penalty set to l1 either explicitly or implicitly eg Lasso
the threshold used is 1e5 Otherwise “mean” is used by default
prefit bool default False Whether a prefit model is expected to be passed into the constructor
directly or not If True transform must be called directly and SelectFromModel can
not be used with crossvalscore GridSearchCV and similar utilities that clone
the estimator Otherwise train the model using fit and thentransform to do feature
selection
normorder nonzero int inf inf default 1 Order of the norm used to filter the vectors of
coefficients below threshold in the case where the coef attribute of the estimator is
of dimension 2
maxfeatures int or None optional The maximum number of features selected scoring above
threshold To disable threshold and only select based on maxfeatures set
thresholdnpinf
New in version 020
Attributes
estimator an estimator The base estimator from which the transformer is built This is stored
only when a nonfitted estimator is passed to the SelectFromModel ie when prefit is
False
threshold float The threshold value used for feature selection
Methods
fitself X y Fit the SelectFromModel metatransformer
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
getsupport self indices Get a mask or integer index of the features selected
inversetransform self X Reverse the transformation operation
partialfit self X y Fit the SelectFromModel metatransformer only once
Continued on next page

Table 6110 – continued from previous page
setparams self params Set the parameters of this estimator
transform self X Reduce X to the selected features
init selfestimator thresholdNone prefitFalse normorder1 maxfeaturesNone
fitselfXyNone fitparams
Fit the SelectFromModel metatransformer
Parameters
Xarraylike of shape nsamples nfeatures The training input samples
yarraylike shape nsamples The target values integers that correspond to classes in
classification real numbers in regression
fitparams Other estimator specific parameters
Returns
self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector

inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
partialfit selfXyNone fitparams
Fit the SelectFromModel metatransformer only once
Parameters
Xarraylike of shape nsamples nfeatures The training input samples
yarraylike shape nsamples The target values integers that correspond to classes in
classification real numbers in regression
fitparams Other estimator specific parameters
Returns
self object
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
Examples using sklearnfeatureselectionSelectFromModel
•Feature selection using SelectFromModel and LassoCV
•Classification of text documents using sparse features
6167sklearnfeatureselection SelectFwe
classsklearnfeatureselection SelectFwe scorefuncfunction fclassif alpha005
Filter Select the pvalues corresponding to Familywise error rate
Read more in the User Guide

Parameters
scorefunc callable Function taking two arrays X and y and returning a pair of arrays scores
pvalues Default is fclassif see below “See also” The default function only works with
classification tasks
alpha float optional The highest uncorrected pvalue for features to keep
Attributes
scores arraylike shapenfeatures Scores of features
pvalues arraylike shapenfeatures pvalues of feature scores
See also
fclassif ANOV A Fvalue between labelfeature for classification tasks
chi2 Chisquared stats of nonnegative features for classification tasks
fregression Fvalue between labelfeature for regression tasks
SelectPercentile Select features based on percentile of the highest scores
SelectKBest Select features based on the k highest scores
SelectFpr Select features based on a false positive rate test
SelectFdr Select features based on an estimated false discovery rate
GenericUnivariateSelect Univariate feature selector with configurable mode
Examples
```
 from sklearndatasets import loadbreastcancer
 from sklearnfeatureselection import SelectFwe chi2
X y  loadbreastcancerreturnXy True
Xshape
569 30
Xnew  SelectFwechi2 alpha001fittransformX y
Xnewshape
569 15
```
Methods
fitself X y Run score function on X y and get the appropriate
features
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
getsupport self indices Get a mask or integer index of the features selected
inversetransform self X Reverse the transformation operation
setparams self params Set the parameters of this estimator
transform self X Reduce X to the selected features
init selfscorefuncfunction fclassif at 0x7efe30bb2158 alpha005
fitselfXy

Run score function on X y and get the appropriate features
Parameters
Xarraylike shape nsamples nfeatures The training input samples
yarraylike shape nsamples The target values class labels in classification real num
bers in regression
Returns
self object
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
6168sklearnfeatureselection RFE
classsklearnfeatureselection RFEestimator nfeaturestoselectNone step1 verbose0
Feature ranking with recursive feature elimination
Given an external estimator that assigns weights to features eg the coefficients of a linear model the goal of
recursive feature elimination RFE is to select features by recursively considering smaller and smaller sets of
features First the estimator is trained on the initial set of features and the importance of each feature is obtained
either through a coef attribute or through a featureimportances attribute Then the least important
features are pruned from current set of features That procedure is recursively repeated on the pruned set until
the desired number of features to select is eventually reached
Read more in the User Guide
Parameters
estimator object A supervised learning estimator with a fit method that provides in
formation about feature importance either through a coef attribute or through a
featureimportances attribute
nfeaturestoselect int or None defaultNone The number of features to select If None
half of the features are selected
step int or float optional default1 If greater than or equal to 1 then step corresponds to
the integer number of features to remove at each iteration If within 00 10 then step
corresponds to the percentage rounded down of features to remove at each iteration
verbose int default0 Controls verbosity of output
Attributes
nfeatures int The number of selected features
support array of shape nfeatures The mask of selected features
ranking array of shape nfeatures The feature ranking such that rankingi corre
sponds to the ranking position of the ith feature Selected ie estimated best features are
assigned rank 1
estimator object The external estimator fit on the reduced dataset

Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters

Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
predictselfX
Reduce X to the selected features and then predict using the underlying estimator
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
yarray of shape nsamples The predicted target values
predictlogproba selfX
Predict class logprobabilities for X
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
parray of shape nsamples nclasses The class logprobabilities of the input samples
The order of the classes corresponds to that in the attribute classes
predictproba selfX
Predict class probabilities for X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
parray of shape nsamples nclasses The class probabilities of the input samples The
order of the classes corresponds to that in the attribute classes
scoreselfXy
Reduce X to the selected features and then return the score of the underlying estimator
Parameters
Xarray of shape nsamples nfeatures The input samples
yarray of shape nsamples The target values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfX
Reduce X to the selected features
Parameters

classsklearnfeatureselection RFECVestimator step1 minfeaturestoselect1 cv'warn'
scoringNone verbose0 njobsNone
Feature ranking with recursive feature elimination and crossvalidated selection of the best number of features
See glossary entry for crossvalidation estimator
Read more in the User Guide
Parameters
estimator object A supervised learning estimator with a fit method that provides in
formation about feature importance either through a coef attribute or through a
featureimportances attribute
step int or float optional default1 If greater than or equal to 1 then step corresponds
to the integer number of features to remove at each iteration If within 00 10 then
step corresponds to the percentage rounded down of features to remove at each itera
tion Note that the last iteration may remove fewer than step features in order to reach
minfeaturestoselect
minfeaturestoselect int default1 The minimum number of features to be selected
This number of features will always be scored even if the difference between the origi
nal feature count and minfeaturestoselect isn't divisible by step
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if yis binary or multiclass sklearnmodelselection
StratifiedKFold is used If the estimator is a classifier or if yis neither binary nor
multiclass sklearnmodelselectionKFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value of None will change from 3fold to 5fold in
v022

scoring string callable or None optional defaultNone A string see model evaluation doc
umentation or a scorer callable object function with signature scorerestimator
X y
verbose int default0 Controls verbosity of output
njobs int or None optional defaultNone Number of cores to run in parallel while fitting
across folds None means 1 unless in a joblibparallelbackend context1
means using all processors See Glossary for more details
Attributes
nfeatures int The number of selected features with crossvalidation
support array of shape nfeatures The mask of selected features
ranking array of shape nfeatures The feature ranking such that rankingi corre
sponds to the ranking position of the ith feature Selected ie estimated best features are
assigned rank 1
gridscores array of shape nsubsetsoffeatures The crossvalidation scores such that
gridscoresi corresponds to the CV score of the ith subset of features
estimator object The external estimator fit on the reduced dataset

decisionfunction selfX
Compute the decision function of X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
score array shape nsamples nclasses or nsamples The decision function of the
input samples The order of the classes corresponds to that in the attribute classes Re
gression and binary classification produce an array of shape nsamples
fitselfXygroupsNone
Fit the RFE model and automatically tune the number of selected features
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples is the number of samples and nfeatures is the total number of features
yarraylike shape nsamples Target values integers for classification real numbers
for regression
groups arraylike shape nsamples optional Group labels for the samples used while
splitting the dataset into traintest set Only used in conjunction with a "Group" cvinstance
egGroupKFold
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters

Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getsupport selfindicesFalse
Get a mask or integer index of the features selected
Parameters
indices boolean default False If True the return value will be an array of integers rather
than a boolean mask
Returns
support array An index that selects the retained features from a feature vector If
indices is False this is a boolean array of shape input features in which an ele
ment is True iff its corresponding feature is selected for retention If indices is True
this is an integer array of shape output features whose values are indices into the input
feature vector
inversetransform selfX
Reverse the transformation operation
Parameters
Xarray of shape nsamples nselectedfeatures The input samples
Returns
Xr array of shape nsamples noriginalfeatures Xwith columns of zeros inserted
where features would have been removed by transform
predictselfX
Reduce X to the selected features and then predict using the underlying estimator
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
yarray of shape nsamples The predicted target values
predictlogproba selfX
Predict class logprobabilities for X
Parameters
Xarray of shape nsamples nfeatures The input samples

Returns
parray of shape nsamples nclasses The class logprobabilities of the input samples
The order of the classes corresponds to that in the attribute classes
predictproba selfX
Predict class probabilities for X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
parray of shape nsamples nclasses The class probabilities of the input samples The
order of the classes corresponds to that in the attribute classes
scoreselfXy
Reduce X to the selected features and then return the score of the underlying estimator
Parameters

yarray of shape nsamples The target values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Reduce X to the selected features
Parameters
Xarray of shape nsamples nfeatures The input samples
Returns
Xr array of shape nsamples nselectedfeatures The input samples with only the se
lected features
Examples using sklearnfeatureselectionRFECV
•Recursive feature elimination with crossvalidation
61610sklearnfeatureselection VarianceThreshold
classsklearnfeatureselection VarianceThreshold threshold00
Feature selector that removes all lowvariance features
616sklearnfeatureselection Feature Selection 1791

This feature selection algorithm looks only at the features X not the desired outputs y and can thus be used
for unsupervised learning
Read more in the User Guide
Parameters
threshold float optional Features with a trainingset variance lower than this threshold will be
removed The default is to keep all features with nonzero variance ie remove the features
that have the same value in all samples
Attributes
variances array shape nfeatures Variances of individual features
Examples
The following dataset has integer features two of which are the same in every sample These are removed with
the default setting for threshold
X 0 2 0 3 0 1 4 3 0 1 1 3
selector VarianceThreshold

able
61611sklearnfeatureselection chi2
sklearnfeatureselection chi2Xy
Compute chisquared stats between each nonnegative feature and class
This score can be used to select the nfeatures features with the highest values for the test chisquared statistic
from X which must contain only nonnegative features such as booleans or frequencies eg term counts in
document classification relative to the classes
Recall that the chisquare test measures dependence between stochastic variables so using this function “weeds
out” the features that are the most likely to be independent of class and therefore irrelevant for classification
Read more in the User Guide
Parameters
Xarraylike sparse matrix shape nsamples nfeaturesin Sample vectors
yarraylike shape nsamples Target vector class labels
Returns
chi2 array shape nfeatures chi2 statistics of each feature
pval array shape nfeatures pvalues of each feature
See also
fclassif ANOV A Fvalue between labelfeature for classification tasks
fregression Fvalue between labelfeature for regression tasks
Notes
Complexity of this algorithm is Onclasses nfeatures

•Feature agglomeration vs univariate selection
•Comparison of Ftest and mutual information
•Pipeline Anova SVM
61614sklearnfeatureselection mutualinfoclassif
sklearnfeatureselection mutualinfoclassif X y discretefeatures'auto'
nneighbors3 copyTrue ran
domstateNone
Estimate mutual information for a discrete target variable
Mutual information MI 1between two random variables is a nonnegative value which measures the depen
dency between the variables It is equal to zero if and only if two random variables are independent and higher
values mean higher dependency
The function relies on nonparametric methods based on entropy estimation from knearest neighbors distances
as described in 2and3 Both methods are based on the idea originally proposed in 4
It can be used for univariate features selection read more in the User Guide
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Feature matrix
yarraylike shape nsamples Target vector
discretefeatures 'auto' bool arraylike default 'auto' If bool then determines whether
to consider all features discrete or continuous If array then it should be either a boolean
mask with shape nfeatures or array with indices of discrete features If 'auto' it is
assigned to False for dense Xand to True for sparse X
nneighbors int default 3 Number of neighbors to use for MI estimation for continuous vari
ables see 2and3 Higher values reduce variance of the estimation but could introduce
a bias
copy bool default True Whether to make a copy of the given data If set to False the initial
data will be overwritten
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator for adding small noise to continuous variables in order
to remove repeated values If int randomstate is the seed used by the random number

generator If RandomState instance randomstate is the random number generator If None
the random number generator is the RandomState instance used by nprandom
Returns
mindarray shape nfeatures Estimated mutual information between each feature and the
target
Notes
1 The term “discrete features” is used instead of naming them “categorical” because it describes the essence
more accurately For example pixel intensities of an image are discrete features but hardly categorical
and you will get better results if mark them as such Also note that treating a continuous variable as
discrete and vice versa will usually give incorrect results so be attentive about that
2 True mutual information can’t be negative If its estimate turns out to be negative it is replaced by zero

Gaussian process classification GPC based on Laplace approximation
The implementation is based on Algorithm 31 32 and 51 of Gaussian Processes for Machine Learning
GPML by Rasmussen and Williams

Internally the Laplace approximation is used for approximating the nonGaussian posterior by a Gaussian
Currently the implementation is restricted to using the logistic link function For multiclass classification
several binary oneversus rest classifiers are fitted Note that this class thus does not implement a true multi
class Laplace approximation
Parameters
kernel kernel object The kernel specifying the covariance function of the GP If None is
passed the kernel “10 RBF10” is used as default Note that the kernel’s hyperpa
rameters are optimized during fitting
optimizer string or callable optional default “fminlbfgsb” Can either be one of the
internally supported optimizers for optimizing the kernel’s parameters specified by a string
or an externally defined optimizer passed as a callable If a callable is passed it must have
the signature
defoptimizerobjfunc initialtheta bounds
objfunc is the objective function to be maximized which
 takes the hyperparameters theta as parameter and an
 optional flag evalgradient which determines if the
 gradient is returned additionally to the function value
initialtheta the initial value for theta which can be
 used by local optimizers
bounds the bounds on the values of theta

 Returned are the best found hyperparameters theta and
 the corresponding value of the target function
returnthetaopt funcmin
Per default the ‘fminlbfgsb’ algorithm from scipyoptimize is used If None is passed
the kernel’s parameters are kept fixed Available internal optimizers are
fminlbfgsb
nrestartsoptimizer int optional default 0 The number of restarts of the optimizer for
finding the kernel’s parameters which maximize the logmarginal likelihood The first run
of the optimizer is performed from the kernel’s initial parameters the remaining ones if
any from thetas sampled loguniform randomly from the space of allowed thetavalues If
greater than 0 all bounds must be finite Note that nrestartsoptimizer0 implies that one
run is performed
maxiterpredict int optional default 100 The maximum number of iterations in New
ton’s method for approximating the posterior during predict Smaller values will reduce
computation time at the cost of worse results
warmstart bool optional default False If warmstarts are enabled the solution of the last
Newton iteration on the Laplace approximation of the posterior mode is used as initializa
tion for the next call of posteriormode This can speed up convergence when poste
riormode is called several times on similar problems as in hyperparameter optimization
Seethe Glossary
copyXtrain bool optional default True If True a persistent copy of the training data is
stored in the object Otherwise just a reference to the training data is stored which might
cause predictions to change if the data is modified externally
randomstate int RandomState instance or None optional default None The generator
used to initialize the centers If int randomstate is the seed used by the random number

generator If RandomState instance randomstate is the random number generator If None
the random number generator is the RandomState instance used by nprandom
multiclass string default Specifies how multiclass classification problems are handled
Supported are “onevsrest” and “onevsone” In “onevsrest” one binary Gaussian
process classifier is fitted for each class which is trained to separate this class from the rest
In “onevsone” one binary Gaussian process classifier is fitted for each pair of classes
which is trained to separate these two classes The predictions of these binary predictors are
combined into multiclass predictions Note that “onevsone” does not support predicting
probability estimates
njobs int or None optional defaultNone The number of jobs to use for the computation
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
Attributes
kernel kernel object The kernel used for prediction In case of binary classification the
structure of the kernel is the same as the one passed as parameter but with optimized hy
perparameters In case of multiclass classification a CompoundKernel is returned which
consists of the different kernels used in the oneversusrest classifiers
logmarginallikelihoodvalue float The logmarginallikelihood of selfkernel
theta
classes arraylike shape nclasses Unique class labels
nclasses int The number of classes in the training data
Examples
```
 from sklearndatasets import loadiris
 from sklearngaussianprocess import GaussianProcessClassifier
 from sklearngaussianprocesskernels import RBF

New in version 018
Methods
fitself X y Fit Gaussian process classification model
getparams self deep Get parameters for this estimator
logmarginallikelihood self theta Returns logmarginal likelihood of theta for training
data
predict self X Perform classification on an array of test vectors X
predictproba self X Return probability estimates for the test vector X
Continued on next page

Table 6117 – continued from previous page
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init self kernelNone optimizer’fminlbfgsb’ nrestartsoptimizer0
maxiterpredict100 warmstartFalse copyXtrainTrue randomstateNone
multiclass’onevsrest’ njobsNone
fitselfXy
Fit Gaussian process classification model
Parameters
Xarraylike shape nsamples nfeatures Training data
yarraylike shape nsamples Target values must be binary
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
logmarginallikelihood selfthetaNone evalgradientFalse
Returns logmarginal likelihood of theta for training data
In the case of multiclass classification the mean logmarginal likelihood of the oneversusrest classifiers
are returned
Parameters
theta arraylike shape nkernelparams or none Kernel hyperparameters for which
the logmarginal likelihood is evaluated In the case of multiclass classification theta may
be the hyperparameters of the compound kernel or of an individual kernel In the latter
case all individual kernel get assigned the same theta values If None the precomputed
logmarginallikelihood of selfkerneltheta is returned
evalgradient bool default False If True the gradient of the logmarginal likelihood with
respect to the kernel hyperparameters at position theta is returned additionally Note that
gradient computation is not supported for nonbinary classification If True theta must not
be None
Returns
loglikelihood float Logmarginal likelihood of theta for training data
loglikelihoodgradient array shape nkernelparams optional Gradient of the log
marginal likelihood with respect to the kernel hyperparameters at position theta Only
returned when evalgradient is True
predictselfX
Perform classification on an array of test vectors X

Parameters
Xarraylike shape nsamples nfeatures
Returns
Carray shape nsamples Predicted target values for X values are from classes
predictproba selfX
Return probability estimates for the test vector X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carraylike shape nsamples nclasses Returns the probability of the samples for
each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearngaussianprocessGaussianProcessClassifier
•Plot classification probability
•Classifier comparison
•Illustration of Gaussian process classification GPC on the XOR dataset

Gaussian process regression GPR
The implementation is based on Algorithm 21 of Gaussian Processes for Machine Learning GPML by Ras
mussen and Williams
In addition to standard scikitlearn estimator API GaussianProcessRegressor
• allows prediction without prior fitting based on the GP prior
• provides an additional method sampleyX which evaluates samples drawn from the GPR prior or pos
terior at given inputs
• exposes a method logmarginallikelihoodtheta which can be used externally for other ways of selecting
hyperparameters eg via Markov chain Monte Carlo
Read more in the User Guide
New in version 018
Parameters
kernel kernel object The kernel specifying the covariance function of the GP If None is
passed the kernel "10 RBF10" is used as default Note that the kernel's hyperpa
rameters are optimized during fitting
alpha float or arraylike optional default 1e10 Value added to the diagonal of the kernel
matrix during fitting Larger values correspond to increased noise level in the observations
This can also prevent a potential numerical issue during fitting by ensuring that the calcu
lated values form a positive definite matrix If an array is passed it must have the same
number of entries as the data used for fitting and is used as datapointdependent noise level
Note that this is equivalent to adding a WhiteKernel with calpha Allowing to specify the
noise level directly as a parameter is mainly for convenience and for consistency with Ridge
optimizer string or callable optional default "fminlbfgsb" Can either be one of the
internally supported optimizers for optimizing the kernel's parameters specified by a string
or an externally defined optimizer passed as a callable If a callable is passed it must have
the signature
defoptimizerobjfunc initialtheta bounds
objfunc is the objective function to be minimized which
 takes the hyperparameters theta as parameter and an
 optional flag evalgradient which determines if the
 gradient is returned additionally to the function value
initialtheta the initial value for theta which can be
 used by local optimizers
bounds the bounds on the values of theta

 Returned are the best found hyperparameters theta and
 the corresponding value of the target function
returnthetaopt funcmin
Per default the 'fminlbfgsb' algorithm from scipyoptimize is used If None is passed
the kernel's parameters are kept fixed Available internal optimizers are

fminlbfgsb
nrestartsoptimizer int optional default 0 The number of restarts of the optimizer for finding the kernel’s parameters which maximize the logmarginal likelihood The first run of the optimizer is performed from the kernel’s initial parameters the remaining ones if any from thetas sampled loguniform randomly from the space of allowed thetavalues If greater than 0 all bounds must be finite Note that nrestartsoptimizer 0 implies that one run is performed
normalizey boolean optional default False Whether the target values y are normalized ie the mean of the observed target values become zero This parameter should be set to True if the target values’ mean is expected to differ considerable from zero When enabled the normalization effectively modifies the GP’s prior based on the data which contradicts the likelihood principle normalization is thus disabled per default
copyXtrain bool optional default True If True a persistent copy of the training data is stored in the object Otherwise just a reference to the training data is stored which might cause predictions to change if the data is modified externally
randomstate int RandomState instance or None optional default None The generator used to initialize the centers If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
Attributes
Xtrain arraylike shape nsamples nfeatures Feature values in training data also required for prediction
ytrain arraylike shape nsamples noutputdims Target values in training data also required for prediction
kernel kernel object The kernel used for prediction The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters
Larraylike shape nsamples nsamples Lowertriangular Cholesky decomposition of the kernel in Xtrain
alpha arraylike shape nsamples Dual coefficients of training data points in kernel space
logmarginallikelihoodvalue float The logmarginallikelihood of selfkernel theta

Methods
fitself X y Fit Gaussian process regression model
getparams self deep Get parameters for this estimator
logmarginallikelihood self theta Returns logmarginal likelihood of theta for training data
predict self X returnstd returncov Predict using the Gaussian process regression model
sampley self X nsamples randomstate Draw samples from Gaussian process and evaluate at X
score self X y sampleweight Returns the coefficient of determination R2 of the prediction
setparams self params Set the parameters of this estimator
init selfkernelNone alpha1e10 optimizer'fminlbfgsb' nrestartsoptimizer0 normalizeyFalse copyXtrainTrue randomstateNone
fitselfXy
Fit Gaussian process regression model
Parameters
Xarraylike shape nsamples nfeatures Training data
yarraylike shape nsamples noutputdims Target values
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
logmarginallikelihood selfthetaNone evalgradientFalse
Returns logmarginal likelihood of theta for training data
Parameters
theta arraylike shape nkernelparams or None Kernel hyperparameters for which the logmarginal likelihood is evaluated If None the precomputed logmarginallikelihood of selfkerneltheta is returned
evalgradient bool default False If True the gradient of the logmarginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally If True theta must not be None
Returns
loglikelihood float Logmarginal likelihood of theta for training data
loglikelihoodgradient array shape nkernelparams optional Gradient of the log marginal likelihood with respect to the kernel hyperparameters at position theta Only returned when evalgradient is True

predictselfXreturnstdFalse returncovFalse
Predict using the Gaussian process regression model
We can also predict based on an unfitted model by using the GP prior In addition to the mean of the pre
dictive distribution also its standard deviation returnstdTrue or covariance returncovTrue Note
that at most one of the two can be requested
Parameters
Xarraylike shape nsamples nfeatures Query points where the GP is evaluated
returnstd bool default False If True the standarddeviation of the predictive distribu
tion at the query points is returned along with the mean
returncov bool default False If True the covariance of the joint predictive distribution
at the query points is returned along with the mean
Returns
ymean array shape nsamples noutputdims Mean of predictive distribution a
query points
ystd array shape nsamples optional Standard deviation of predictive distribution at
query points Only returned when returnstd is True
ycov array shape nsamples nsamples optional Covariance of joint predictive dis
tribution a query points Only returned when returncov is True
sampley selfXnsamples1 randomstate0
Draw samples from Gaussian process and evaluate at X
Parameters
Xarraylike shape nsamplesX nfeatures Query points where the GP samples are
evaluated
nsamples int default 1 The number of samples drawn from the Gaussian process
randomstate int RandomState instance or None optional default0 If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Returns
ysamples array shape nsamplesX noutputdims nsamples Values of
nsamples samples drawn from Gaussian process and evaluated at query points
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights

Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Kernel which is composed of a set of other kernels
New in version 018
Parameters
kernels list of Kernel objects The other kernels
Attributes
bounds Returns the logtransformed bounds on the theta
hyperparameters Returns a list of all hyperparameter specifications
ndims Returns the number of nonfixed hyperparameters of the kernel
theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Return the kernel kX Y and optionally its gradient
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selfkernels
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Note that this compound kernel returns the results of all simple kernel stacked along an additional axis
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined
Returns

Karray shape nsamplesX nsamplesY nkernels Kernel kX Y
Kgradient array shape nsamplesX nsamplesX ndims nkernels The gradient
of the kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX nkernels Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams

Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
Examples using sklearngaussianprocesskernelsExpSineSquared
•Comparison of kernel ridge and Gaussian process regression
•Illustration of prior and posterior Gaussian process for different kernels
•Gaussian process regression GPR on Mauna Loa CO2 data
6177sklearngaussianprocesskernels Exponentiation
classsklearngaussianprocesskernels Exponentiation kernel exponent
Exponentiate kernel by given exponent
The resulting kernel is defined as kexpX Y kX Y exponent
New in version 018
Parameters
kernel Kernel object The base kernel
exponent float The exponent for the base kernel
Attributes
bounds Returns the logtransformed bounds on the theta
hyperparameters Returns a list of all hyperparameter
ndims Returns the number of nonfixed hyperparameters of the kernel
theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Return the kernel kX Y and optionally its gradient
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selfkernel exponent
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient

Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the
kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel

setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
6178sklearngaussianprocesskernels Hyperparameter
classsklearngaussianprocesskernels Hyperparameter
A kernel hyperparameter’s specification in form of a namedtuple
New in version 018
Attributes
name string Alias for field number 0
valuetype string Alias for field number 1
bounds pair of floats 0 or “fixed” Alias for field number 2
nelements int default1 Alias for field number 3
fixed bool default None Alias for field number 4
Methods
count
index Raises ValueError if the value is not present
init selfargs kwargs
Initialize self See helptypeself for accurate signature
call args kwargs
Call self as a function
bounds
Alias for field number 2
count
fixed
Alias for field number 4
index

Raises ValueError if the value is not present
nelements
Alias for field number 3
name
Alias for field number 0
valuetype
Alias for field number 1
6179sklearngaussianprocesskernels Kernel
classsklearngaussianprocesskernels Kernel
Base class for all kernels
New in version 018
Attributes
bounds Returns the logtransformed bounds on the theta
hyperparameters Returns a list of all hyperparameter specifications
ndims Returns the number of nonfixed hyperparameters of the kernel
theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Evaluate the kernel
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selfargs kwargs
Initialize self See helptypeself for accurate signature
call selfXYNone evalgradientFalse
Evaluate the kernel
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters

diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
61710sklearngaussianprocesskernels Matern
classsklearngaussianprocesskernels Maternlengthscale10 lengthscalebounds1e
051000000 nu15
Matern kernel
The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by
an additional parameter nu The smaller nu the less smooth the approximated function is For nuinf the kernel
617sklearngaussianprocess Gaussian Processes 1821

becomes equivalent to the RBF kernel and for nu05 to the absolute exponential kernel Important intermediate values are nu15 once differentiable functions and nu25 twice differentiable functions
See Rasmussen and Williams 2006 pp84 for details regarding the different variants of the Matern kernel
New in version 018
Parameters
lengthscale float or array with shape nfeatures default 10 The length scale of the kernel
If a float an isotropic kernel is used If an array an anisotropic kernel is used where each
dimension of l defines the lengthscale of the respective feature dimension
lengthscalebounds pair of floats 0 default 1e5 1e5 The lower and upper bound on
lengthscale
nufloat default 15 The parameter nu controlling the smoothness of the learned function
The smaller nu the less smooth the approximated function is For nuinf the kernel be
comes equivalent to the RBF kernel and for nu05 to the absolute exponential kernel Im
portant intermediate values are nu15 once differentiable functions and nu25 twice
differentiable functions Note that values of nu not in 05 15 25 inf incur a consid
erably higher computational cost appr 10 times higher since they require to evaluate the
modified Bessel function Furthermore in contrast to l nu is kept fixed to its initial value
and not optimized
Attributes
anisotropic
bounds Returns the logtransformed bounds on the theta
hyperparameterlengthscale
hyperparameters Returns a list of all hyperparameter specifications
ndims Returns the number of nonfixed hyperparameters of the kernel

theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selflengthscale10 lengthscalebounds1e05 1000000 nu15
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead

evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined Only supported when Y is None
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the
kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object

Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
Examples using sklearngaussianprocesskernelsMatern

61711sklearngaussianprocesskernels PairwiseKernel
classsklearngaussianprocesskernels PairwiseKernel gamma10
gammabounds1e05
1000000 metric’linear’ pair
wisekernelskwargsNone
Wrapper for kernels in sklearnmetricspairwise
A thin wrapper around the functionality of the kernels in sklearnmetricspairwise
Note Evaluation of evalgradient is not analytic but numeric and all kernels support only isotropic dis
tances The parameter gamma is considered to be a hyperparameter and may be optimized The other
kernel parameters are set directly at initialization and are kept fixed
New in version 018
Parameters
gamma float 0 default 10 Parameter gamma of the pairwise kernel specified by metric
gammabounds pair of floats 0 default 1e5 1e5 The lower and upper bound on
gamma
metric string or callable default “linear” The metric to use when calculating kernel between
instances in a feature array If metric is a string it must be one of the metrics in pair
wisePAIRWISEKERNELFUNCTIONS If metric is “precomputed” X is assumed to be
a kernel matrix Alternatively if metric is a callable function it is called on each pair of
instances rows and the resulting value recorded The callable should take two arrays from
X as input and return a value indicating the distance between them
pairwisekernelskwargs dict default None All entries of this dict if any are passed as
keyword arguments to the pairwise kernel function
Attributes
bounds Returns the logtransformed bounds on the theta
hyperparametergamma
hyperparameters Returns a list of all hyperparameter specifications
ndims Returns the number of nonfixed hyperparameters of the kernel

theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Return the kernel kX Y and optionally its gradient
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selfgamma10 gammabounds1e05 1000000 metric'linear' pair
wisekernelskwargsNone
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined Only supported when Y is None
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the
kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel's hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y

Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
61712sklearngaussianprocesskernels Product
classsklearngaussianprocesskernels Productk1k2
Productkernel k1 k2 of two kernels k1 and k2
The resulting kernel is defined as kprodX Y k1X Y k2X Y
New in version 018
Parameters
k1Kernel object The first basekernel of the productkernel
k2Kernel object The second basekernel of the productkernel
Attributes
bounds Returns the logtransformed bounds on the theta
hyperparameters Returns a list of all hyperparameter

ndims Returns the number of nonfixed hyperparameters of the kernel
theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Return the kernel kX Y and optionally its gradient
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selfk1k2
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the
kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y

Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa

naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel
61713sklearngaussianprocesskernels RBF
classsklearngaussianprocesskernels RBFlengthscale10 lengthscalebounds1e05
1000000
Radialbasis function kernel aka squaredexponential kernel
The RBF kernel is a stationary kernel It is also known as the “squared exponential” kernel It is parameterized
by a lengthscale parameter lengthscale0 which can either be a scalar isotropic variant of the kernel or a
vector with the same number of dimensions as the inputs X anisotropic variant of the kernel The kernel is
given by
kxi xj exp1 2 dxi lengthscale xj lengthscale2
This kernel is infinitely differentiable which implies that GPs with this kernel as covariance function have mean
square derivatives of all orders and are thus very smooth
New in version 018

Parameters
lengthscale float or array with shape nfeatures default 10 The length scale of the kernel
If a float an isotropic kernel is used If an array an anisotropic kernel is used where each
dimension of l defines the lengthscale of the respective feature dimension
lengthscalebounds pair of floats 0 default 1e5 1e5 The lower and upper bound on
lengthscale
Attributes
anisotropic
bounds Returns the logtransformed bounds on the theta
hyperparameterlengthscale
hyperparameters Returns a list of all hyperparameter specifications
ndims Returns the number of nonfixed hyperparameters of the kernel
theta Returns the flattened logtransformed nonfixed hyperparameters
Methods
call self X Y evalgradient Return the kernel kX Y and optionally its gradient
clonewiththeta self theta Returns a clone of self with given hyperparameters
theta
diag self X Returns the diagonal of the kernel kX X
getparams self deep Get parameters of this kernel
isstationary self Returns whether the kernel is stationary
setparams self params Set the parameters of this kernel
init selflengthscale10 lengthscalebounds1e05 1000000
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the
returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re
spect to the kernel hyperparameter is determined Only supported when Y is None
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the
kernel kX X with respect to the hyperparameter of the kernel Only returned when
evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns

bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam
eters theta
clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel

Examples using sklearngaussianprocesskernelsRBF

init selfnoiselevel10 noiselevelbounds1e05 1000000
call selfXYNone evalgradientFalse
Return the kernel kX Y and optionally its gradient
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Yarray shape nsamplesY nfeatures optional defaultNone Right argument of the returned kernel kX Y If None kX X if evaluated instead
evalgradient bool optional defaultFalse Determines whether the gradient with re spect to the kernel hyperparameter is determined Only supported when Y is None
Returns
Karray shape nsamplesX nsamplesY Kernel kX Y
Kgradient array opt shape nsamplesX nsamplesX ndims The gradient of the kernel kX X with respect to the hyperparameter of the kernel Only returned when evalgradient is True
bounds
Returns the logtransformed bounds on the theta
Returns
bounds array shape ndims 2 The logtransformed bounds on the kernel’s hyperparam eters theta

clonewiththeta selftheta
Returns a clone of self with given hyperparameters theta
Parameters
theta array shape ndims The hyperparameters
diagselfX
Returns the diagonal of the kernel kX X
The result of this method is identical to npdiagselfX however it can be evaluated more efficiently
since only the diagonal is evaluated
Parameters
Xarray shape nsamplesX nfeatures Left argument of the returned kernel kX Y
Returns
Kdiag array shape nsamplesX Diagonal of kernel kX X
getparams selfdeepTrue
Get parameters of this kernel
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
hyperparameters
Returns a list of all hyperparameter specifications
isstationary self
Returns whether the kernel is stationary
ndims
Returns the number of nonfixed hyperparameters of the kernel
setparams selfparams
Set the parameters of this kernel
The method works on simple kernels as well as on nested kernels The latter have parameters of the form
componentparameter so that it’s possible to update each component of a nested object
Returns
self
theta
Returns the flattened logtransformed nonfixed hyperparameters
Note that theta are typically the logtransformed values of the kernel’s hyperparameters as this representa
tion of the search space is more amenable for hyperparameter search as hyperparameters like lengthscales
naturally live on a logscale
Returns
theta array shape ndims The nonfixed logtransformed hyperparameters of the kernel

Examples using sklearngaussianprocesskernelsWhiteKernel
•Comparison of kernel ridge and Gaussian process regression
•Gaussian process regression GPR with noiselevel estimation
•Gaussian process regression GPR on Mauna Loa CO2 data
618sklearnisotonic Isotonic regression
User guide See the Isotonic regression section for further details
isotonicIsotonicRegression ymin ymax
Isotonic regression model
6181sklearnisotonic IsotonicRegression
classsklearnisotonic IsotonicRegression yminNone ymaxNone increasingTrue
outofbounds'nan'
Isotonic regression model
The isotonic regression optimization problem is defined by
min sum wi yi yi 2
subject to yi yj whenever Xi Xj
andminy ymin maxy ymax
where
•yi are inputs real numbers
•yi are fitted
•Xspecifies the order If Xis nondecreasing then yis nondecreasing
•wi are optional strictly positive weights default to 10
Read more in the User Guide
Parameters
ymin optional default None If not None set the lowest value of the fit to ymin
ymax optional default None If not None set the highest value of the fit to ymax
increasing boolean or string optional default True If boolean whether or not to fit the
isotonic regression with y increasing or decreasing
The string value "auto" determines whether y should increase or decrease based on the
Spearman correlation estimate's sign
outofbounds string optional default "nan" The outofbounds parameter handles
how xvalues outside of the training domain are handled When set to "nan" predicted
yvalues will be NaN When set to "clip" predicted yvalues will be set to the value corre
sponding to the nearest train interval endpoint When set to "raise" allow interp1d to
throw ValueError

Attributes
Xmin float Minimum value of input array Xfor left bound
Xmax float Maximum value of input array Xfor right bound
ffunction The stepwise interpolating function that covers the input domain X
Notes
Ties are broken using the secondary method from Leeuw 1977

Methods
fitself X y sampleweight Fit the model using X y as training data
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
predict self T Predict new data by linear interpolation
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
transform self T Transform new data by linear interpolation
init selfyminNone ymaxNone increasingTrue outofbounds’nan’
fitselfXysampleweightNone
Fit the model using X y as training data
Parameters
Xarraylike shapensamples Training data
yarraylike shapensamples Training target

sampleweight arraylike shapensamples optional default None Weights If set to
None all weights will be set to 1 equal weights
Returns
self object Returns an instance of self
Notes
X is stored for future use as transform needs X to interpolate new input data
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfT
Predict new data by linear interpolation
Parameters
Tarraylike shapensamples Data to transform
Returns
Tarray shapensamples Transformed data
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X

sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfT
Transform new data by linear interpolation
Parameters
Tarraylike shapensamples Data to transform
Returns
Tarray shapensamples The transformed data
Examples using sklearnisotonicIsotonicRegression
•Isotonic Regression
isotoniccheckincreasing x y Determine whether y is monotonically correlated with x
isotonicisotonicregression y   Solve the isotonic regression model
6182sklearnisotonic checkincreasing
sklearnisotonic checkincreasing xy
Determine whether y is monotonically correlated with x
y is found increasing or decreasing with respect to x based on a Spearman correlation test
Parameters
xarraylike shapensamples Training data
yarraylike shapensamples Training target
Returns
618sklearnisotonic Isotonic regression 1841

increasingbool boolean Whether the relationship is increasing or decreasing
Notes
The Spearman correlation coefficient is estimated from the data and the sign of the resulting estimate is used as the result
In the event that the 95 confidence interval based on Fisher transform spans zero a warning is raised

imputeSimpleImputer missingvalues Imputation transformer for completing missing values
imputeIterativeImputer estimator Multivariate imputer that estimates each feature from all the others
imputeMissingIndicator missingvalues Binary indicators for missing values
6191sklearnimpute SimpleImputer
classsklearnimpute SimpleImputer missingvaluesnan strategy'mean' fillvalueNone verbose0 copyTrue addindicatorFalse
Imputation transformer for completing missing values
Read more in the User Guide
Parameters
missingvalues number string npnan default or None The placeholder for the missing values All occurrences of missingvalues will be imputed
strategy string optional default"mean" The imputation strategy
• If "mean" then replace missing values using the mean along each column Can only be used with numeric data
• If "median" then replace missing values using the median along each column Can only be used with numeric data
• If "mostfrequent" then replace missing using the most frequent value along each column Can be used with strings or numeric data
• If "constant" then replace missing values with fillvalue Can be used with strings or numeric data
New in version 020 strategy"constant" for fixed value imputation
fillvalue string or numerical value optional defaultNone When strategy "constant" fillvalue is used to replace all occurrences of missingvalues If left to the default fillvalue will be 0 when imputing numerical data and "missingvalue" for strings or object data types
verbose integer optional default0 Controls the verbosity of the imputer
copy boolean optional defaultTrue If True a copy of X will be created If False imputation will be done inplace whenever possible Note that in the following cases a new copy will always be made even if copyFalse
• If X is not an array of floating values
• If X is encoded as a CSR matrix
• If addindicatorTrue
addindicator boolean optional defaultFalse If True a MissingIndicator transform will stack onto output of the imputer's transform This allows a predictive estimator to account for missingness despite imputation If a feature has no missing values at fittrain

time the feature won’t appear on the missing indicator even if there are missing values at
transformtest time
Attributes
statistics array of shape nfeatures The imputation fill value for each feature
indicator sklearnimputeMissingIndicator Indicator used to add binary indi
cators for missing values None if addindicator is False
See also
IterativeImputer Multivariate imputation of missing values
Notes
Columns which only contained missing values at fit are discarded upon transform if strategy is not “con
stant”

pleposteriorFalse maxiter10 tol0001
nnearestfeaturesNone initialstrategy‘mean’
imputationorder’ascending’ minvalueNone
maxvalueNone verbose0 randomstateNone
addindicatorFalse
Multivariate imputer that estimates each feature from all the others
A strategy for imputing missing values by modeling each feature with missing values as a function of other
features in a roundrobin fashion
Read more in the User Guide
Note This estimator is still experimental for now the predictions and the API might change without any
deprecation cycle To use it you need to explicitly import enableiterativeimputer
 explicitly require this experimental feature
 from sklearnexperimental import enableiterativeimputer noqa
 now you can import normally from sklearnimpute
 from sklearnimpute import IterativeImputer
Parameters
estimator estimator object defaultBayesianRidge The estimator to use at each step of
the roundrobin imputation If sampleposterior is True the estimator must support
returnstd in itspredict method
missingvalues int npnan optional defaultnpnan The placeholder for the missing values
All occurrences of missingvalues will be imputed
sampleposterior boolean defaultFalse Whether to sample from the Gaussian predictive
posterior of the fitted estimator for each imputation Estimator must support returnstd
in itspredict method if set to True Set toTrue if usingIterativeImputer for
multiple imputations
maxiter int optional default10 Maximum number of imputation rounds to perform
before returning the imputations computed during the final round A round is a sin
gle imputation of each feature with missing values The stopping criterion is met
onceabsmaxXt Xt1absmaxXknownvals tol where
Xt isXat iteration t Note that early stopping is only applied if
sampleposteriorFalse
tolfloat optional default1e3 Tolerance of the stopping condition
nnearestfeatures int optional defaultNone Number of other features to use to estimate
the missing values of each feature column Nearness between features is measured using
the absolute correlation coefficient between each feature pair after initial imputation To
ensure coverage of features throughout the imputation process the neighbor features are
not necessarily nearest but are drawn with probability proportional to correlation for each
imputed target feature Can provide significant speedup when the number of features is
huge IfNone all features will be used
initialstrategy str optional default”mean” Which strategy to use to initialize the missing
values Same as the strategy parameter in sklearnimputeSimpleImputer
Valid values “mean” “median” “mostfrequent” or “constant”

imputationorder str optional default”ascending” The order in which the features will be imputed Possible values
“ascending” From features with fewest missing values to most
“descending” From features with most missing values to fewest
“roman” Left to right
“arabic” Right to left
“random” A random order for each round
minvalue float optional defaultNone Minimum possible imputed value Default of None will set minimum to negative infinity
maxvalue float optional defaultNone Maximum possible imputed value Default of None will set maximum to positive infinity
verbose int optional default0 Verbosity flag controls the debug messages that are issued as functions are evaluated The higher the more verbose Can be 0 1 or 2
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use Randomizes selection of estimator features if nnearestfeatures is not None the imputationorder ifrandom and the sampling from posterior if sampleposterior is True Use an integer for determinism See the Glossary
addindicator boolean optional defaultFalse If True a MissingIndicator transform will stack onto output of the imputer’s transform This allows a predictive estimator to account for missingness despite imputation If a feature has no missing values at fittrain time the feature won’t appear on the missing indicator even if there are missing values at transformtest time
Attributes
initialimputer object of type sklearnimputeSimpleImputer Imputer used to initialize the missing values
imputationsequence list of tuples Each tuple has featidx neighborfeatidx estimator wherefeatidx is the current feature to be imputed neighborfeatidx is the array of other features used to impute the current feature and estimator is the trained estimator used for the imputation Length isselfnfeatureswithmissing selfniter
niter int Number of iteration rounds that occurred Will be less than selfmaxiter if early stopping criterion was reached
nfeatureswithmissing int Number of features with missing values
indicator sklearnimputeMissingIndicator Indicator used to add binary indicators for missing values None if addindicator is False
See also
SimpleImputer Univariate imputation of missing values
Notes
To support imputation in inductive mode we store each feature’s estimator during the fit phase and predict without refitting in order during the transform phase

Features which contain all missing values at fit are discarded upon transform
Features with missing values during transform which did not have any missing values during fit will be imputed with the initial imputation method only

Fits the imputer on X and return self
Parameters
Xarraylike shape nsamples nfeatures Input data where "nsamples" is the number of samples and "nfeatures" is the number of features
yignored
Returns
self object Returns self
fittransform selfXyNone
Fits the imputer on X and return the transformed X
Parameters
Xarraylike shape nsamples nfeatures Input data where "nsamples" is the number of samples and "nfeatures" is the number of features
yignored
Returns
Xtarraylike shape nsamples nfeatures The imputed input data
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators
Returns

params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Imputes all missing values in X
Note that this is stochastic and that if randomstate is not fixed repeated calls or permuted input will
yield different results
Parameters
Xarraylike shape nsamples nfeatures The input data to complete
Returns
Xtarraylike shape nsamples nfeatures The imputed input data
Examples using sklearnimputeIterativeImputer
•Imputing missing values with variants of IterativeImputer
•Imputing missing values before building an estimator
6193sklearnimpute MissingIndicator
classsklearnimpute MissingIndicator missingvaluesnan features’missingonly’
sparse’auto’ erroronnewTrue
Binary indicators for missing values
Note that this component typically should not be used in a vanilla Pipeline consisting of transformers and a
classifier but rather could be added using a FeatureUnion orColumnTransformer
Read more in the User Guide
Parameters
missingvalues number string npnan default or None The placeholder for the missing
values All occurrences of missingvalues will be indicated True in the output array
the other values will be marked as False
features str optional Whether the imputer mask should represent all or a subset of features
• If “missingonly” default the imputer mask will only represent features containing
missing values during fit time
• If “all” the imputer mask will represent all features
sparse boolean or “auto” optional Whether the imputer mask format should be sparse or
dense
• If “auto” default the imputer mask will be of same type as input
• If True the imputer mask will be a sparse matrix

• If False the imputer mask will be a numpy array
erroronnew boolean optional If True default transform will raise an error when there are features with missing values in transform that have no missing values in fit This is applicable only when featuresmissingonly
Attributes
features ndarray shape nmissingfeatures or nfeatures The features indices which will be returned when calling transform They are computed during fit For featuresall it is torangenfeatures

620sklearnkernelapproximation Kernel Approximation
Thesklearnkernelapproximation module implements several approximate kernel feature maps base on
Fourier transforms
User guide See the Kernel Approximation section for further details
kernelapproximation
AdditiveChi2Sampler Approximate feature map for additive chi2 kernel
kernelapproximationNystroem kernel Approximate a kernel map using a subset of the training
data
Continued on next page

Table 6141 – continued from previous page
kernelapproximationRBFSampler gamma
Approximates feature map of an RBF kernel by Monte
Carlo approximation of its Fourier transform
kernelapproximation
SkewedChi2Sampler Approximates feature map of the “skewed chisquared”
kernel by Monte Carlo approximation of its Fourier trans
form
6201sklearnkernelapproximation AdditiveChi2Sampler
classsklearnkernelapproximation AdditiveChi2Sampler samplesteps2 sam
pleintervalNone
Approximate feature map for additive chi2 kernel
Uses sampling the fourier transform of the kernel characteristic at regular intervals
Since the kernel that is to be approximated is additive the components of the input vectors can be treated
separately Each entry in the original space is transformed into 2samplesteps1 features where samplesteps
is a parameter of the method Typical values of samplesteps include 1 2 and 3
Optimal choices for the sampling interval for certain data ranges can be computed see the reference The
default values should be reasonable
Read more in the User Guide
Parameters
samplesteps int optional Gives the number of complex sampling points
sampleinterval float optional Sampling interval Must be specified when samplesteps not
in 123

Whether the return value is an array of sparse matrix depends on the type of the input X
6202sklearnkernelapproximation Nystroem
classsklearnkernelapproximation Nystroem kernel’rbf’ gammaNone coef0None
degreeNone kernelparamsNone
ncomponents100 randomstateNone
Approximate a kernel map using a subset of the training data
Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis
Read more in the User Guide
Parameters
kernel string or callable default”rbf” Kernel map to be approximated A callable should
accept two arguments and the keyword arguments passed to this object as kernelparams
and should return a floating point number
gamma float defaultNone Gamma parameter for the RBF laplacian polynomial exponen
tial chi2 and sigmoid kernels Interpretation of the default value is left to the kernel see the
documentation for sklearnmetricspairwise Ignored by other kernels
coef0 float defaultNone Zero coefficient for polynomial and sigmoid kernels Ignored by
other kernels
degree float defaultNone Degree of the polynomial kernel Ignored by other kernels
kernelparams mapping of string to any optional Additional parameters keyword argu
ments for kernel function passed as callable object
ncomponents int Number of features to construct How many data points will be used to
construct the mapping
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Attributes

components array shape ncomponents nfeatures Subset of training points used to con
struct the feature map
componentindices array shape ncomponents Indices of components in the training
set
normalization array shape ncomponents ncomponents Normalization matrix needed
for embedding Square root of the kernel matrix on components

Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Apply feature map to X
Computes an approximate feature map using the kernel between some training points and X
Parameters
Xarraylike shapensamples nfeatures Data to transform
Returns
Xtransformed array shapensamples ncomponents Transformed data
Examples using sklearnkernelapproximationNystroem
•Explicit feature map approximation for RBF kernels

scikitlearn user guide Release 0213
6203sklearnkernelapproximation RBFSampler

621sklearnkernelridge Kernel Ridge Regression
Modulesklearnkernelridge implements kernel ridge regression
User guide See the Kernel ridge regression section for further details
kernelridgeKernelRidge alpha kernel Kernel ridge regression
6211sklearnkernelridge KernelRidge
classsklearnkernelridge KernelRidge alpha1 kernel’linear’ gammaNone degree3 coef01 kernelparamsNone
Kernel ridge regression
Kernel ridge regression KRR combines ridge regression linear least squares with l2norm regularization with the kernel trick It thus learns a linear function in the space induced by the respective kernel and the data For nonlinear kernels this corresponds to a nonlinear function in the original space
The form of the model learned by KRR is identical to support vector regression SVR However different loss functions are used KRR uses squared error loss while support vector regression uses epsiloninsensitive loss both combined with l2 regularization In contrast to SVR fitting a KRR model can be done in closedform and is typically faster for mediumsized datasets On the other hand the learned model is nonsparse and thus slower than SVR which learns a sparse model for epsilon 0 at predictiontime
This estimator has builtin support for multivariate regression ie when y is a 2darray of shape nsamples ntargets
Read more in the User Guide
Parameters
alpha float arraylike shape ntargets Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates Alpha corresponds to 2C1 in other linear models such as LogisticRegression or LinearSVC If an array is

passed penalties are assumed to be specific to the targets Hence they must correspond in number
kernel string or callable default”linear” Kernel mapping used internally A callable should accept two arguments and the keyword arguments passed to this object as kernelparams and should return a floating point number Set to “precomputed” in order to pass a precomputed kernel matrix to the estimator methods instead of samples
gamma float defaultNone Gamma parameter for the RBF laplacian polynomial exponential chi2 and sigmoid kernels Interpretation of the default value is left to the kernel see the documentation for sklearnmetricspairwise Ignored by other kernels
degree float default3 Degree of the polynomial kernel Ignored by other kernels
coef0 float default1 Zero coefficient for polynomial and sigmoid kernels Ignored by other kernels
kernelparams mapping of string to any optional Additional parameters keyword arguments for kernel function passed as callable object
Attributes
dualcoef array shape nsamples or nsamples ntargets Representation of weight vectors in kernel space
Xfit arraylike sparse matrix shape nsamples nfeatures Training data which is also required for prediction If kernel “precomputed” this is instead the precomputed training matrix shape nsamples nsamples

Bayesian ARD regression
Fit the weights of a regression model using an ARD prior The weights of the regression model are assumed to be in Gaussian distributions Also estimate the parameters lambda precisions of the distributions of the weights and alpha precision of the distribution of the noise The estimation is done by an iterative procedures

Evidence Maximization
Read more in the User Guide
Parameters
niter int optional Maximum number of iterations Default is 300
tolfloat optional Stop the algorithm if w has converged Default is 1e3
alpha1 float optional Hyperparameter shape parameter for the Gamma distribution prior over the alpha parameter Default is 1e6
alpha2 float optional Hyperparameter inverse scale parameter rate parameter for the Gamma distribution prior over the alpha parameter Default is 1e6
lambda1 float optional Hyperparameter shape parameter for the Gamma distribution prior over the lambda parameter Default is 1e6
lambda2 float optional Hyperparameter inverse scale parameter rate parameter for the Gamma distribution prior over the lambda parameter Default is 1e6
computescore boolean optional If True compute the objective function at each step of the model Default is False
thresholdlambda float optional threshold for removing pruning weights with high preci sion from the computation Default is 1e4
fitintercept boolean optional whether to calculate the intercept for this model If set to false no intercept will be used in calculations eg data is expected to be already centered Default is True
normalize boolean optional default False This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized be fore regression by subtracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten
verbose boolean optional default False Verbose mode when fitting the model
Attributes
coef array shape nfeatures Coefficients of the regression model mean of distribution
alpha float estimated precision of the noise
lambda array shape nfeatures estimated precisions of the weights
sigma array shape nfeatures nfeatures estimated variancecovariance matrix of the weights
scores float if computed value of the objective function to be maximized
Notes
For an example see exampleslinearmodelplotardpy

Bayesian ridge regression
Fit a Bayesian ridge model See the Notes section for details on this implementation and the optimization of the
regularization parameters lambda precision of the weights and alpha precision of the noise
Read more in the User Guide
Parameters
niter int optional Maximum number of iterations Default is 300 Should be greater than or
equal to 1
tolfloat optional Stop the algorithm if w has converged Default is 1e3
alpha1 float optional Hyperparameter shape parameter for the Gamma distribution prior
over the alpha parameter Default is 1e6
alpha2 float optional Hyperparameter inverse scale parameter rate parameter for the
Gamma distribution prior over the alpha parameter Default is 1e6
lambda1 float optional Hyperparameter shape parameter for the Gamma distribution prior
over the lambda parameter Default is 1e6
lambda2 float optional Hyperparameter inverse scale parameter rate parameter for the
Gamma distribution prior over the lambda parameter Default is 1e6
computescore boolean optional If True compute the log marginal likelihood at each itera
tion of the optimization Default is False
fitintercept boolean optional default True Whether to calculate the intercept for this model
The intercept is not treated as a probabilistic parameter and thus has no associated variance
If set to False no intercept will be used in calculations eg data is expected to be already
centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten
verbose boolean optional default False Verbose mode when fitting the model
Attributes
coef array shape nfeatures Coefficients of the regression model mean of distribution

intercept float Independent term in decision function Set to 00 if fitintercept
False
alpha float Estimated precision of the noise
lambda float Estimated precision of the weights
sigma array shape nfeatures nfeatures Estimated variancecovariance matrix of the
weights
scores array shape niter 1 If computedscore is True value of the log marginal
likelihood to be maximized at each iteration of the optimization The array starts with the
value of the log marginal likelihood obtained for the initial values of alpha and lambda and
ends with the value obtained for the estimated alpha and lambda
niter int The actual number of iterations to reach the stopping criterion
Notes
There exist several strategies to perform Bayesian ridge regression This implementation is based on the algo
rithm described in Appendix A of Tipping 2001 where updates of the regularization parameters are done as
suggested in MacKay 1992 Note that according to A New View of Automatic Relevance Determination Wipf
and Nagarajan 2008 these update rules do not guarantee that the marginal likelihood is increasing between two
consecutive iterations of the optimization

Minimizes the objective function
1 2nsamples y Xw22
 alpha l1ratio w1
 05alpha1 l1ratio w22
If you are interested in controlling the L1 and L2 penalty separately keep in mind that this is equivalent to
aL1 bL2

where
alpha a b andl1ratio a a b
The parameter l1ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda
parameter in glmnet Specifically l1ratio 1 is the lasso penalty Currently l1ratio 001 is not reliable
unless you supply your own sequence of alpha
Read more in the User Guide
Parameters
alpha float optional Constant that multiplies the penalty terms Defaults to 10 See the
notes for the exact mathematical meaning of this parameter‘‘alpha 0‘‘ is equivalent to an
ordinary least square solved by the LinearRegression object For numerical reasons
usingalpha 0 with theLasso object is not advised Given this you should use the
LinearRegression object
l1ratio float The ElasticNet mixing parameter with 0 l1ratio 1 For
l1ratio 0 the penalty is an L2 penalty For l1ratio 1 it is an L1 penalty
For0 l1ratio 1 the penalty is a combination of L1 and L2
fitintercept bool Whether the intercept should be estimated or not If False the data is
assumed to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
precompute True False arraylike Whether to use a precomputed Gram matrix to speed up
calculations The Gram matrix can also be passed as argument For sparse input this option
is alwaysTrue to preserve sparsity
maxiter int optional The maximum number of iterations
copyX boolean optional default True If True X will be copied else it may be overwritten
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
positive bool optional When set to True forces the coefficients to be positive
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection ‘random’
selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
coef array shape nfeatures ntargets nfeatures parameter vector w in the cost func
tion formula

sparsecoef scipysparse matrix shape nfeatures 1 ntargets nfeatures sparse
representation of the fitted coef
intercept float array shape ntargets independent term in decision function
niter arraylike shape ntargets number of iterations run by the coordinate descent solver
to reach the specified tolerance

XyNone copyXTrue coefinitNone verboseFalse returnniterFalse posi
tiveFalse checkinputTrue params
Compute elastic net path with coordinate descent
The elastic net optimization function varies for mono and multioutputs
For monooutput tasks it is
1 2nsamples y Xw22
 alpha l1ratio w1
 05alpha1 l1ratio w22
For multioutput tasks it is
1 2 nsamples Y XWFro2
 alpha l1ratio W21
 05alpha1 l1ratio WFro2
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide

Parameters
Xarraylike shape nsamples nfeatures Training data Pass directly as Fortran contiguous data to avoid unnecessary memory duplication If yis monooutput then X can be sparse
yndarray shape nsamples or nsamples noutputs Target values
l1ratio float optional float between 0 and 1 passed to elastic net scaling between l1 and l2 penalties l1ratio1 corresponds to the Lasso
eps float Length of the path eps1e3 means that alphamin alphamax 1e3
nalphas int optional Number of alphas along the regularization path
alphas ndarray optional List of alphas where to compute the models If None alphas are set automatically
precompute True False 'auto' arraylike Whether to use a precomputed Gram matrix to speed up calculations If set to auto let us decide The Gram matrix can also be passed as argument
Xyarraylike optional Xy npdotXT y that can be precomputed It is useful only when the Gram matrix is precomputed
copyX boolean optional default True If True X will be copied else it may be over written
coefinit array shape nfeatures None The initial values of the coefficients
verbose bool or integer Amount of verbosity
returnniter bool whether to return the number of iterations or not
positive bool default False If set to True forces coefficients to be positive Only allowed whenyndim 1
checkinput bool default True Skip input validation checks including the Gram matrix when provided assuming there are handled by the caller when checkinputFalse
params kwargs keyword arguments passed to the coordinate descent solver
Returns
alphas array shape nalphas The alphas along the path where models are computed
coefs array shape nfeatures nalphas or noutputs nfeatures nalphas Coefficients along the path
dualgaps array shape nalphas The dual gaps at the end of the optimization for each alpha
niters arraylike shape nalphas The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha Is returned when returnniter is set to True

Notes
For an example see exampleslinearmodelplotlassocoordinatedescentpathpy
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sparsecoef
sparse representation of the fitted coef

Examples using sklearnlinearmodelElasticNet
•Lasso and Elastic Net for Sparse Signals
•Train error vs Test error
6224sklearnlinearmodel HuberRegressor
classsklearnlinearmodel HuberRegressor epsilon135 maxiter100 alpha00001
warmstartFalse fitinterceptTrue tol1e05
Linear regression model that is robust to outliers
The Huber Regressor optimizes the squared loss for the samples where y Xw sigma
epsilon and the absolute loss for the samples where y Xw sigma epsilon where w
and sigma are parameters to be optimized The parameter sigma makes sure that if y is scaled up or down by a
certain factor one does not need to rescale epsilon to achieve the same robustness Note that this does not take
into account the fact that the different features of X may be of different scales
This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring
their effect
Read more in the User Guide
New in version 018
Parameters
epsilon float greater than 10 default 135 The parameter epsilon controls the number of
samples that should be classified as outliers The smaller the epsilon the more robust it is
to outliers
maxiter int default 100 Maximum number of iterations that scipyoptimizefminlbfgsb
should run for
alpha float default 00001 Regularization parameter
warmstart bool default False This is useful if the stored attributes of a previously used
model has to be reused If set to False then the coefficients will be rewritten for every call
to fit See the Glossary
fitintercept bool default True Whether or not to fit the intercept This can be set to False if
the data is already centered around the origin
tolfloat default 1e5 The iteration will stop when maxproj gi i 1
ntol where pgi is the ith component of the projected gradient
Attributes
coef array shape nfeatures Features got by optimizing the Huber loss
intercept float Bias
scale float The value by which y Xw c is scaled down
niter int Number of iterations that fminlbfgsb has run for
Changed in version 020 In SciPy 100 the number of lbfgs iterations may exceed
maxiter niter will now report at most maxiter
outliers array shape nsamples A boolean mask which is set to True where the samples
are identified as outliers

6226sklearnlinearmodel Lasso
classsklearnlinearmodel Lassoalpha10 fitinterceptTrue normalizeFalse precom puteFalse copyXTrue maxiter1000 tol00001 warmstartFalse positiveFalse randomstateNone selec tion’cyclic’
Linear Model trained with L1 prior as regularizer aka the Lasso
The optimization objective for Lasso is
1 2 nsamples y Xw22 alpha w1
Technically the Lasso model is optimizing the same objective function as the Elastic Net with l1ratio10 no L2 penalty
Read more in the User Guide
Parameters
alpha float optional Constant that multiplies the L1 term Defaults to 10 alpha 0 is equivalent to an ordinary least square solved by the LinearRegression object For numerical reasons using alpha 0 with theLasso object is not advised Given this you should use the LinearRegression object
fitintercept boolean optional default True Whether to calculate the intercept for this model If set to False no intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized be fore regression by subtracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before callingfit on an estimator with normalizeFalse
precompute True False arraylike defaultFalse Whether to use a precomputed Gram ma trix to speed up calculations If set to auto let us decide The Gram matrix can also be passed as argument For sparse input this option is always True to preserve sparsity
copyX boolean optional default True If True X will be copied else it may be overwritten
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the optimization code checks the dual gap for optimality and continues until it is smaller than tol
warmstart bool optional When set to True reuse the solution of the previous call to fit as initialization otherwise just erase the previous solution See the Glossary
positive bool optional When set to True forces the coefficients to be positive

randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection ‘random’
selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4

0 0963257
Methods
fitself X y Xy Fit the model using X y as training data
getparams self deep Get parameters for this estimator
predict self X Predict using the linear model
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfalpha10 fitinterceptTrue verboseFalse normalizeTrue precompute'auto'
maxiter500 eps2220446049250313e16 copyXTrue fitpathTrue posi
tiveFalse
fitselfXyXyNone
Fit the model using X y as training data
Parameters
Xarraylike shape nsamples nfeatures Training data
yarraylike shape nsamples or nsamples ntargets Target values
Xyarraylike shape nsamples or nsamples ntargets optional Xy npdotXT y
that can be precomputed It is useful only when the Gram matrix is precomputed
Returns
self object returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples

Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
6228sklearnlinearmodel LinearRegression
classsklearnlinearmodel LinearRegression fitinterceptTrue normalizeFalse
copyXTrue njobsNone
Ordinary least squares Linear Regression
Parameters
fitintercept boolean optional default True whether to calculate the intercept for this model
If set to False no intercept will be used in calculations eg data is expected to be already
centered

normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten
njobs int or None optional defaultNone The number of jobs to use for the computation
This will only provide speedup for ntargets 1 and sufficient large problems None means
1 unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
Attributes
coef array shape nfeatures or ntargets nfeatures Estimated coefficients for the linear
regression problem If multiple targets are passed during the fit y 2D this is a 2D array of
shape ntargets nfeatures while if only one target is passed this is a 1D array of length
nfeatures
intercept array Independent term in the linear model
Notes
From the implementation point of view this is just plain Ordinary Least Squares scipylinalglstsq wrapped as
a predictor object
Examples
```
 import numpy as np
 from sklearnlinearmodel import LinearRegression

6229sklearnlinearmodel LogisticRegression
classsklearnlinearmodel LogisticRegression penalty'l2' dualFalse tol00001
C10 fitinterceptTrue inter
ceptscaling1 classweightNone
randomstateNone solver'warn'
maxiter100 multiclass'warn' ver
bose0 warmstartFalse njobsNone
l1ratioNone
Logistic Regression aka logit MaxEnt classifier
In the multiclass case the training algorithm uses the onevsrest OvR scheme if the 'multiclass' option is set to 'ovr' and uses the crossentropy loss if the 'multiclass' option is set to 'multinomial' Currently the 'multinomial' option is supported only by the 'lbfgs' 'sag' 'saga' and 'newtoncg' solvers
This class implements regularized logistic regression using the 'liblinear' library 'newtoncg' 'sag' 'saga' and 'lbfgs' solvers Note that regularization is applied by default It can handle both dense and sparse input Use Cordered arrays or CSR matrices containing 64bit floats for optimal performance any other input format will be converted and copied
The 'newtoncg' 'sag' and 'lbfgs' solvers support only L2 regularization with primal formulation or no reg ularization The 'liblinear' solver supports both L1 and L2 regularization with a dual formulation only for the L2 penalty The ElasticNet regularization is only supported by the 'saga' solver
Read more in the User Guide
Parameters
penalty str 'l1' 'l2' 'elasticnet' or 'none' optional default'l2' Used to specify the norm used in the penalization The 'newtoncg' 'sag' and 'lbfgs' solvers support only l2 penal ties 'elasticnet' is only supported by the 'saga' solver If 'none' not supported by the liblinear solver no regularization is applied
New in version 019 l1 penalty with SAGA solver allowing 'multinomial' L1
dual bool optional defaultFalse Dual or primal formulation Dual formulation is only implemented for l2 penalty with liblinear solver Prefer dualFalse when nsamples nfeatures
tolfloat optional default1e4 Tolerance for stopping criteria
Cfloat optional default10 Inverse of regularization strength must be a positive float Like in support vector machines smaller values specify stronger regularization
fitintercept bool optional defaultTrue Specifies if a constant aka bias or intercept should be added to the decision function
interceptscaling float optional default1 Useful only when the solver 'liblinear' is used and selffitintercept is set to True In this case x becomes x selfinterceptscaling ie a "synthetic" feature with constant value equal to interceptscaling is ap pended to the instance vector The intercept becomes interceptscaling syntheticfeatureweight
Note the synthetic feature weight is subject to l1l2 regularization as all other features To lessen the effect of regularization on synthetic feature weight and therefore on the intercept interceptscaling has to be increased
classweight dict or 'balanced' optional defaultNone Weights associated with classes in the formclasslabel weight If not given all classes are supposed to have weight one

The “balanced” mode uses the values of y to automatically adjust weights inversely pro portional to class frequencies in the input data as nsamples nclasses np bincounty
Note that these weights will be multiplied with sampleweight passed through the fit method if sampleweight is specified
New in version 017 classweight’balanced’
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when solver ‘sag’ or ‘liblinear’
solver str ‘newtoncg’ ‘lbfgs’ ‘liblinear’ ‘sag’ ‘saga’ optional default’liblinear’ Al gorithm to use in the optimization problem
• For small datasets ‘liblinear’ is a good choice whereas ‘sag’ and ‘saga’ are faster for large ones
• For multiclass problems only ‘newtoncg’ ‘sag’ ‘saga’ and ‘lbfgs’ handle multinomial loss ‘liblinear’ is limited to oneversusrest schemes
• ‘newtoncg’ ‘lbfgs’ ‘sag’ and ‘saga’ handle L2 or no penalty
• ‘liblinear’ and ‘saga’ also handle L1 penalty
• ‘saga’ also supports ‘elasticnet’ penalty
• ‘liblinear’ does not handle no penalty
Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approxi mately the same scale You can preprocess the data with a scaler from sklearnpreprocessing
New in version 017 Stochastic Average Gradient descent solver
New in version 019 SAGA solver
Changed in version 020 Default will change from ‘liblinear’ to ‘lbfgs’ in 022
maxiter int optional default100 Maximum number of iterations taken for the solvers to converge
multiclass str ‘ovr’ ‘multinomial’ ‘auto’ optional default’ovr’ If the option chosen is ‘ovr’ then a binary problem is fit for each label For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution even when the data is binary ‘multinomial’ is unavailable when solver’liblinear’ ‘auto’ selects ‘ovr’ if the data is binary or if solver’liblinear’ and otherwise selects ‘multinomial’
New in version 018 Stochastic Average Gradient descent solver for ‘multinomial’ case
Changed in version 020 Default will change from ‘ovr’ to ‘auto’ in 022
verbose int optional default0 For the liblinear and lbfgs solvers set verbose to any positive number for verbosity
warmstart bool optional defaultFalse When set to True reuse the solution of the pre vious call to fit as initialization otherwise just erase the previous solution Useless for liblinear solver See the Glossary
New in version 017 warmstart to support lbfgs newtoncg sagsaga solvers
njobs int or None optional defaultNone Number of CPU cores used when parallelizing over classes if multiclass’ovr’” This parameter is ignored when the solver is set to

‘liblinear’ regardless of whether ‘multiclass’ is specified or not None means 1 unless in
ajoblibparallelbackend context1means using all processors See Glossary
for more details
l1ratio float or None optional defaultNone The ElasticNet mixing parameter with
0 l1ratio 1 Only used if penaltyelasticnet Setting
l1ratio0 is equivalent to using penaltyl2 while setting l1ratio1 is
equivalent to using penaltyl1 For0 l1ratio 1 the penalty is a combi
nation of L1 and L2
Attributes
classes array shape nclasses A list of class labels known to the classifier
coef array shape 1 nfeatures or nclasses nfeatures Coefficient of the features in the
decision function
coef is of shape 1 nfeatures when the given problem is binary In particular when
multiclassmultinomial coef corresponds to outcome 1 True and coef
corresponds to outcome 0 False
intercept array shape 1 or nclasses Intercept aka bias added to the decision func
tion
Iffitintercept is set to False the intercept is set to zero intercept
is of shape 1 when the given problem is binary In particular when
multiclassmultinomial intercept corresponds to outcome 1 True and
intercept corresponds to outcome 0 False
niter array shape nclasses or 1 Actual number of iterations for all classes If binary
or multinomial it returns only 1 element For liblinear solver only the maximum number
of iteration across all classes is given
Changed in version 020 In SciPy 100 the number of lbfgs iterations may exceed
maxiter niter will now report at most maxiter
See also
SGDClassifier incrementally trained logistic regression when given the parameter losslog
LogisticRegressionCV Logistic regression with builtin cross validation
Notes
The underlying C implementation uses a random number generator to select features when fitting the model
It is thus not uncommon to have slightly different results for the same input data If that happens try with a
smaller tol parameter
Predict output may not match that of standalone liblinear in certain cases See differences from liblinear in the
narrative documentation

fitself X y sampleweight Fit the model according to the given training data
getparams self deep Get parameters for this estimator
predict self X Predict class labels for samples in X
predictlogproba self X Log of probability estimates
predictproba self X Probability estimates
score self X y sampleweight Returns the mean accuracy on the given test data and labels
setparams self params Set the parameters of this estimator
sparsify self Convert coefficient matrix to sparse format
init selfpenalty’l2’ dualFalse tol00001 C10 fitinterceptTrue intercept_scaling1 classweightNone randomstateNone solver’warn’ maxiter100 multiclass’warn’ verbose0 warmstartFalse njobsNone l1ratioNone
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence scores per sample class combination In the binary case confidence score for selfclasses1 where 0 means this class would be predicted

densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXysampleweightNone
Fit the model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target vector relative to X
sampleweight arraylike shape nsamples optional Array of weights that are assigned
to individual samples If not provided then each sample is given unit weight
New in version 017 sampleweight support to LogisticRegression
Returns
self object
Notes
The SAGA solver supports both float64 and float32 bit arrays
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
predictlogproba selfX
Log of probability estimates
The returned estimates for all classes are ordered by the label of classes
Parameters
Xarraylike shape nsamples nfeatures

Returns
Tarraylike shape nsamples nclasses Returns the logprobability of the sample for
each class in the model where classes are ordered as they are in selfclasses
predictproba selfX
Probability estimates
The returned estimates for all classes are ordered by the label of classes
For a multiclass problem if multiclass is set to be “multinomial” the softmax function is used to find
the predicted probability of each class Else use a onevsrest approach ie calculate the probability of
each class assuming it to be positive using the logistic function and normalize these values across all the
classes
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tarraylike shape nsamples nclasses Returns the probability of the sample for each
class in the model where classes are ordered as they are in selfclasses
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more
memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator

Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
Examples using sklearnlinearmodelLogisticRegression
•Compact estimator representations
•Comparison of Calibration of Classifiers
•Probability Calibration curves

warmstartFalse randomstateNone selec
tion’cyclic’
Multitask Lasso model trained with L1L2 mixednorm as regularizer
The optimization objective for Lasso is
1 2 nsamples Y XW2Fro alpha W21
Where

W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters
alpha float optional Constant that multiplies the L1L2 term Defaults to 10
fitintercept boolean whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection ‘random’
selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
coef array shape ntasks nfeatures Parameter vector W in the cost function formula
Note thatcoef stores the transpose of WWT
intercept array shape ntasks independent term in decision function
niter int number of iterations run by the coordinate descent solver to reach the specified
tolerance

```

fitselfXy

Fit MultiTaskElasticNet model with coordinate descent

Parameters

Xndarray shape nsamples nfeatures Data

yndarray shape nsamples ntasks Target Will be cast to X’s dtype if necessary

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortrancontiguous numpy array if necessary

To avoid memory reallocation it is advised to allocate the initial data in memory directly using that format

getparams selfdeepTrue

Get parameters for this estimator

Parameters

deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators

Returns
params mapping of string to any Parameter names mapped to their values
pathXyl1ratio05 eps0001 nalphas100 alphasNone precompute’auto’ XyNone
copyXTrue coefinitNone verboseFalse returnniterFalse positiveFalse
checkinputTrue params
Compute elastic net path with coordinate descent
The elastic net optimization function varies for mono and multioutputs
For monooutput tasks it is
1 2nsamples y Xw22
 alpha l1ratio w1
 05alpha1 l1ratio w22
For multioutput tasks it is
1 2 nsamples Y XWFro2
 alpha l1ratio W21
 05alpha1 l1ratio WFro2
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures Training data Pass directly as Fortran
contiguous data to avoid unnecessary memory duplication If yis monooutput then X
can be sparse
yndarray shape nsamples or nsamples noutputs Target values
l1ratio float optional float between 0 and 1 passed to elastic net scaling between l1 and
l2 penalties l1ratio1 corresponds to the Lasso
eps float Length of the path eps1e3 means that alphamin alphamax
1e3
nalphas int optional Number of alphas along the regularization path
alphas ndarray optional List of alphas where to compute the models If None alphas are
set automatically
precompute True False ‘auto’ arraylike Whether to use a precomputed Gram matrix
to speed up calculations If set to auto let us decide The Gram matrix can also be
passed as argument
Xyarraylike optional Xy npdotXT y that can be precomputed It is useful only
when the Gram matrix is precomputed
copyX boolean optional default True If True X will be copied else it may be over
written
coefinit array shape nfeatures None The initial values of the coefficients
verbose bool or integer Amount of verbosity

returnniter bool whether to return the number of iterations or not
positive bool default False If set to True forces coefficients to be positive Only allowed
whenyndim 1
checkinput bool default True Skip input validation checks including the Gram matrix
when provided assuming there are handled by the caller when checkinputFalse
params kwargs keyword arguments passed to the coordinate descent solver
Returns
alphas array shape nalphas The alphas along the path where models are computed
coefs array shape nfeatures nalphas or noutputs nfeatures nalphas Coefficients
along the path
dualgaps array shape nalphas The dual gaps at the end of the optimization for each
alpha
niters arraylike shape nalphas The number of iterations taken by the coordinate
descent optimizer to reach the specified tolerance for each alpha Is returned when
returnniter is set to True

ElasticNetCV
Notes
For an example see exampleslinearmodelplotlassocoordinatedescentpathpy
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X

sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sparsecoef
sparse representation of the fitted coef
Examples using sklearnlinearmodelMultiTaskLasso

Where
W21 sumi sqrtsumj wij 2
ie the sum of norm of each row
Read more in the User Guide
Parameters

alpha float optional Constant that multiplies the L1L2 term Defaults to 10
l1ratio float The ElasticNet mixing parameter with 0 l1ratio 1 For l1ratio 1 the
penalty is an L1L2 penalty For l1ratio 0 it is an L2 penalty For 0 l1ratio
1 the penalty is a combination of L1L2 and L2
fitintercept boolean whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection ‘random’
selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
intercept array shape ntasks Independent term in decision function
coef array shape ntasks nfeatures Parameter vector W in the cost function formula If
a 1D y is passed in at fit non multitask usage coef is then a 1D array Note that coef
stores the transpose of WWT
niter int number of iterations run by the coordinate descent solver to reach the specified
tolerance

predict self X Predict using the linear model
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfalpha10 l1ratio05 fitinterceptTrue normalizeFalse copyXTrue
maxiter1000 tol00001 warmstartFalse randomstateNone selection’cyclic’
fitselfXy
Fit MultiTaskElasticNet model with coordinate descent
Parameters
Xndarray shape nsamples nfeatures Data
yndarray shape nsamples ntasks Target Will be cast to X’s dtype if necessary
Notes
Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically
convert the X input as a Fortrancontiguous numpy array if necessary
To avoid memory reallocation it is advised to allocate the initial data in memory directly using that format
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values

pathXyl1ratio05 eps0001 nalphas100 alphasNone precompute’auto’ XyNone
copyXTrue coefinitNone verboseFalse returnniterFalse positiveFalse
checkinputTrue params
Compute elastic net path with coordinate descent
The elastic net optimization function varies for mono and multioutputs
For monooutput tasks it is
1 2nsamples y Xw22
 alpha l1ratio w1
 05alpha1 l1ratio w22
For multioutput tasks it is
1 2 nsamples Y XWFro2
 alpha l1ratio W21
 05alpha1 l1ratio WFro2
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures Training data Pass directly as Fortran
contiguous data to avoid unnecessary memory duplication If yis monooutput then X
can be sparse
yndarray shape nsamples or nsamples noutputs Target values
l1ratio float optional float between 0 and 1 passed to elastic net scaling between l1 and
l2 penalties l1ratio1 corresponds to the Lasso
eps float Length of the path eps1e3 means that alphamin alphamax
1e3
nalphas int optional Number of alphas along the regularization path
alphas ndarray optional List of alphas where to compute the models If None alphas are
set automatically
precompute True False ‘auto’ arraylike Whether to use a precomputed Gram matrix
to speed up calculations If set to auto let us decide The Gram matrix can also be
passed as argument
Xyarraylike optional Xy npdotXT y that can be precomputed It is useful only
when the Gram matrix is precomputed
copyX boolean optional default True If True X will be copied else it may be over
written
coefinit array shape nfeatures None The initial values of the coefficients
verbose bool or integer Amount of verbosity
returnniter bool whether to return the number of iterations or not
positive bool default False If set to True forces coefficients to be positive Only allowed
whenyndim 1

checkinput bool default True Skip input validation checks including the Gram matrix
when provided assuming there are handled by the caller when checkinputFalse
params kwargs keyword arguments passed to the coordinate descent solver
Returns
alphas array shape nalphas The alphas along the path where models are computed
coefs array shape nfeatures nalphas or noutputs nfeatures nalphas Coefficients
along the path
dualgaps array shape nalphas The dual gaps at the end of the optimization for each
alpha
niters arraylike shape nalphas The number of iterations taken by the coordinate
descent optimizer to reach the specified tolerance for each alpha Is returned when
returnniter is set to True

Notes
For an example see exampleslinearmodelplotlassocoordinatedescentpathpy
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns

score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sparsecoef
sparse representation of the fitted coef
62212sklearnlinearmodel OrthogonalMatchingPursuit
classsklearnlinearmodel OrthogonalMatchingPursuit nnonzerocoefsNone
tolNone fitinterceptTrue nor
malizeTrue precompute’auto’
Orthogonal Matching Pursuit model OMP
Read more in the User Guide
Parameters
nnonzerocoefs int optional Desired number of nonzero entries in the solution If None
by default this value is set to 10 of nfeatures
tolfloat optional Maximum norm of the residual If not None overrides nnonzerocoefs
fitintercept boolean optional whether to calculate the intercept for this model If set to false
no intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default True This parameter is ignored when fitintercept
is set to False If True the regressors X will be normalized before regression by sub
tracting the mean and dividing by the l2norm If you wish to standardize please use
sklearnpreprocessingStandardScaler before calling fit on an estimator
withnormalizeFalse
precompute True False ‘auto’ default ‘auto’ Whether to use a precomputed Gram and
Xy matrix to speed up calculations Improves performance when ntargets ornsamples is
very large Note that if you already have such matrices you can pass them directly to the fit
method
Attributes
coef array shape nfeatures or ntargets nfeatures parameter vector w in the formula
intercept float or array shape ntargets independent term in decision function

niter int or arraylike Number of active features across every target

OrthogonalMatchingPursuitCV
Notes
Orthogonal matching pursuit was introduced in G Mallat Z Zhang Matching pursuits with timefrequency dictionaries IEEE Transactions on Signal Processing V ol 41 No 12 December 1993 pp 33973415 httpblanchepolytechniquefrmallatpapiersMallatPursuit93pdf
This implementation is based on Rubinstein R Zibulevsky M and Elad M Efficient Implementation of the KSVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report CS Technion April 2008 httpswwwcstechnionacilronrubinPublicationsKSVDOMPv2pdf
Examples
```
 from sklearnlinearmodel import OrthogonalMatchingPursuit
 from sklearndatasets import makeregression
X y  makeregressionnoise4 randomstate0
reg  OrthogonalMatchingPursuitfitX y
regscoreX y
09991
regpredictX1
array783854
```

Passive Aggressive Classifier
Read more in the User Guide
Parameters
Cfloat Maximum step size regularization Defaults to 10
fitintercept bool defaultFalse Whether the intercept should be estimated or not If False
the data is assumed to be already centered
maxiter int optional default1000 The maximum number of passes over the training data
aka epochs It only impacts the behavior in the fit method and not the partialfit
New in version 019
tolfloat or None optional default1e3 The stopping criterion If it is not None the itera
tions will stop when loss previousloss tol
New in version 019
earlystopping bool defaultFalse Whether to use early stopping to terminate training when
validation score is not improving If set to True it will automatically set aside a stratified
fraction of training data as validation and terminate training when validation score is not
improving by at least tol for niternochange consecutive epochs
New in version 020
validationfraction float default01 The proportion of training data to set aside as validation
set for early stopping Must be between 0 and 1 Only used if earlystopping is True
New in version 020
622sklearnlinearmodel Generalized Linear Models 1915

niternochange int default5 Number of iterations with no improvement to wait before early stopping
New in version 020
shuffle bool defaultTrue Whether or not the training data should be shuffled after each epoch
verbose integer optional The verbosity level
loss string optional The loss function to be used hinge equivalent to PAI in the reference paper squaredhinge equivalent to PAII in the reference paper
njobs int or None optional defaultNone The number of CPUs to use to do the OV A One Versus All for multiclass problems computation None means 1 unless in a joblib parallelbackend context1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
warmstart bool optional When set to True reuse the solution of the previous call to fit as initialization otherwise just erase the previous solution See the Glossary
Repeatedly calling fit or partialfit when warmstart is True can result in a different solution than when calling fit a single time because of the way the data is shuffled
classweight dict classlabel weight or “balanced” or None optional Preset for the classweight fit parameter
Weights associated with classes If not given all classes are supposed to have weight one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro portional to class frequencies in the input data as nsamples nclasses np bincounty
New in version 017 parameter classweight to automatically weight samples
average bool or int optional When set to True computes the averaged SGD weights and stores the result in the coef attribute If set to an int greater than 1 averaging will begin once the total number of samples seen reaches average So average10 will begin averaging after seeing 10 samples
New in version 019 parameter average to use weights averaging in SGD
Attributes
coef array shape 1 nfeatures if nclasses 2 else nclasses nfeatures Weights assigned to the features
intercept array shape 1 if nclasses 2 else nclasses Constants in decision function
niter int The actual number of iterations to reach the stopping criterion For multiclass fits it is the maximum over every binary fit

idationfraction01 niternochange5 shuffleTrue verbose0 loss‘hinge’
njobsNone randomstateNone warmstartFalse classweightNone aver
ageFalse
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples

Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXycoefinitNone interceptinitNone
Fit linear model with Passive Aggressive algorithm
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data
ynumpy array of shape nsamples Target values
coefinit array shape nclassesnfeatures The initial coefficients to warmstart the
optimization
interceptinit array shape nclasses The initial intercept to warmstart the optimiza
tion
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone
Fit linear model with Passive Aggressive algorithm
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Subset of the training data
ynumpy array of shape nsamples Subset of the target values
classes array shape nclasses Classes across all calls to partialfit Can be obtained
by vianpuniqueyall where yall is the target vector of the entire dataset This
argument is required for the first call to partialfit and can be omitted in the subsequent
calls Note that y doesn’t need to contain all labels in classes
Returns
self returns an instance of self

predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
Examples using sklearnlinearmodelPassiveAggressiveClassifier
•Outofcore classification of text documents
•Comparing various online solvers
•Classification of text documents using sparse features

classweight fit parameter
Weights associated with classes If not given all classes are supposed to have weight one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
Attributes
coef array shape 1 nfeatures if nclasses 2 else nclasses nfeatures Weights
assigned to the features
intercept array shape 1 if nclasses 2 else nclasses Constants in decision function
niter int The actual number of iterations to reach the stopping criterion For multiclass fits
it is the maximum over every binary fit

fleTrue verbose0 eta010 njobsNone randomstate0 earlystoppingFalse val
idationfraction01 niternochange5 classweightNone warmstartFalse
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXycoefinitNone interceptinitNone sampleweightNone
Fit linear model with Stochastic Gradient Descent
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data

ynumpy array shape nsamples Target values
coefinit array shape nclasses nfeatures The initial coefficients to warmstart the op
timization
interceptinit array shape nclasses The initial intercept to warmstart the optimiza
tion
sampleweight arraylike shape nsamples optional Weights applied to individual
samples If not provided uniform weights are assumed These weights will be multiplied
with classweight passed through the constructor if classweight is specified
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone sampleweightNone
Perform one epoch of stochastic gradient descent on given samples
Internally this method uses maxiter 1 Therefore it is not guaranteed that a minimum of the cost
function is reached after calling it once Matters such as objective convergence and early stopping should
be handled by the user
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Subset of the training data
ynumpy array shape nsamples Subset of the target values
classes array shape nclasses Classes across all calls to partialfit Can be obtained by
vianpuniqueyall where yall is the target vector of the entire dataset This
argument is required for the first call to partialfit and can be omitted in the subsequent
calls Note that y doesn’t need to contain all labels in classes
sampleweight arraylike shape nsamples optional Weights applied to individual
samples If not provided uniform weights are assumed
Returns
self returns an instance of self
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample

scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
Examples using sklearnlinearmodelPerceptron
•Outofcore classification of text documents

loss‘absoluteloss’ randomstateNone
RANSAC RANdom SAmple Consensus algorithm
RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set More information can be found in the general documentation of linear models

A detailed description of the algorithm can be found in the documentation of the linearmodel subpackage
Read more in the User Guide
Parameters
baseestimator object optional Base estimator object which implements the following meth
ods
•fitX y Fit model to given training data and target values
•scoreX y Returns the mean accuracy on the given test data which is used for the
stop criterion defined by stopscore Additionally the score is used to decide which
of two equally large consensus sets is chosen as the better one
•predictX Returns predicted values using the linear model which is used to com
pute residual error using loss function
Ifbaseestimator is None then baseestimatorsklearnlinearmodel
LinearRegression is used for target values of dtype float
Note that the current implementation only supports regression estimators
minsamples int 1 or float 0 1 optional Minimum number of samples cho
sen randomly from original data Treated as an absolute number of samples for
minsamples 1 treated as a relative number ceilminsamples X
shape0 forminsamples 1 This is typically chosen as the minimal number
of samples necessary to estimate the given baseestimator By default a sklearn
linearmodelLinearRegression estimator is assumed and minsamples is
chosen asXshape1 1
residualthreshold float optional Maximum residual for a data sample to be classified as an
inlier By default the threshold is chosen as the MAD median absolute deviation of the
target values y
isdatavalid callable optional This function is called with the randomly selected data before
the model is fitted to it isdatavalidX y If its return value is False the current
randomly chosen subsample is skipped
ismodelvalid callable optional This function is called with the estimated model and the
randomly selected data ismodelvalidmodel X y If its return value is False
the current randomly chosen subsample is skipped Rejecting samples with this function is
computationally costlier than with isdatavalid ismodelvalid should there
fore only be used if the estimated model is needed for making the rejection decision
maxtrials int optional Maximum number of iterations for random sample selection
maxskips int optional Maximum number of iterations that can be skipped due to finding
zero inliers or invalid data defined by isdatavalid or invalid models defined by
ismodelvalid
New in version 019
stopninliers int optional Stop iteration if at least this number of inliers are found
stopscore float optional Stop iteration if score is greater equal than this threshold
stopprobability float in range 0 1 optional RANSAC iteration stops if at least one outlier
free set of the training data is sampled in RANSAC This requires to generate at least N
samples iterations
N log1 probability log1 e m

where the probability confidence is typically set to high value such as 099 the default and e is the current fraction of inliers wrt the total number of samples
loss string callable optional default “absoluteloss” String inputs “absoluteloss” and “squaredloss” are supported which find the absolute loss and squared loss per sample re spectively
Ifloss is a callable then it should be a function that takes two arrays as inputs the true and predicted value and returns a 1D array with the ith value of the array corresponding to the loss on Xi
If the loss on a sample is greater than the residualthreshold then this sample is classified as an outlier
randomstate int RandomState instance or None optional default None The generator used to initialize the centers If int randomstate is the seed used by the random number gener ator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
Attributes
estimator object Best fitted model copy of the baseestimator object
ntrials int Number of random selection trials until one of the stop criteria is met It is always maxtrials
inliermask bool array of shape nsamples Boolean mask of inliers classified as True
nskipsnoinliers int Number of iterations skipped due to finding zero inliers
New in version 019
nskipsinvaliddata int Number of iterations skipped due to invalid data defined by isdatavalid
New in version 019
nskipsinvalidmodel int Number of iterations skipped due to an invalid model defined by ismodelvalid
New in version 019

Fit estimator using RANSAC algorithm
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Training data
yarraylike shape nsamples or nsamples ntargets Target values
sampleweight arraylike shape nsamples Individual weights for each sample raises
error if sampleweight is passed and baseestimator fit method does not support it
Raises
ValueError If no valid consensus set could be found This occurs if isdatavalid and
ismodelvalid return False for all maxtrials randomly chosen subsamples
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the estimated model
This is a wrapper for estimatorpredictX
Parameters
Xnumpy array of shape nsamples nfeatures
Returns
yarray shape nsamples or nsamples ntargets Returns predicted values
scoreselfXy
Returns the score of the prediction
This is a wrapper for estimatorscoreX y
Parameters
Xnumpy array or sparse matrix of shape nsamples nfeatures Training data

yarray shape nsamples or nsamples ntargets Target values
Returns
zfloat Score of the prediction
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnlinearmodelRANSACRegressor
•Robust linear model estimation using RANSAC
•TheilSen Regression
•Robust linear estimator fitting

classsklearnlinearmodel Ridgealpha10 fitinterceptTrue normalizeFalse
copyXTrue maxiterNone tol0001 solver’auto’
randomstateNone
Linear least squares with l2 regularization
Minimizes the objective function
y Xw22 alpha w22
This model solves a regression model where the loss function is the linear least squares function and regulariza
tion is given by the l2norm Also known as Ridge Regression or Tikhonov regularization This estimator has
builtin support for multivariate regression ie when y is a 2darray of shape nsamples ntargets
Read more in the User Guide
Parameters
alpha float arraylike shape ntargets Regularization strength must be a positive float
Regularization improves the conditioning of the problem and reduces the variance of the es
timates Larger values specify stronger regularization Alpha corresponds to C1 in other
linear models such as LogisticRegression or LinearSVC If an array is passed penalties are
assumed to be specific to the targets Hence they must correspond in number
fitintercept boolean Whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
copyX boolean optional default True If True X will be copied else it may be overwritten

maxiter int optional Maximum number of iterations for conjugate gradient solver For ‘sparsecg’ and ‘lsqr’ solvers the default value is determined by scipysparselinalg For ‘sag’ solver the default value is 1000
tolfloat Precision of the solution
solver ‘auto’ ‘svd’ ‘cholesky’ ‘lsqr’ ‘sparsecg’ ‘sag’ ‘saga’ Solver to use in the com putational routines
• ‘auto’ chooses the solver automatically based on the type of data
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients More stable for singular matrices than ‘cholesky’
• ‘cholesky’ uses the standard scipylinalgsolve function to obtain a closedform solution
• ‘sparsecg’ uses the conjugate gradient solver as found in scipysparselinalgcg As an iterative algorithm this solver is more appropriate than ‘cholesky’ for largescale data possibility to set tol andmaxiter
• ‘lsqr’ uses the dedicated regularized leastsquares routine scipysparselinalglsqr It is the fastest and uses an iterative procedure
• ‘sag’ uses a Stochastic Average Gradient descent and ‘saga’ uses its improved unbiased version named SAGA Both methods also use an iterative procedure and are often faster than other solvers when both nsamples and nfeatures are large Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale You can preprocess the data with a scaler from sklearnpreprocessing
All last five solvers support both dense and sparse data However only ‘sag’ and ‘sparsecg’ supports sparse input when fitintercept is True
New in version 017 Stochastic Average Gradient descent solver
New in version 019 SAGA solver
randomstate int RandomState instance or None optional default None The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when solver ‘sag’
New in version 017 randomstate to support Stochastic Average Gradient
Attributes
coef array shape nfeatures or ntargets nfeatures Weight vectors
intercept float array shape ntargets Independent term in decision function Set to 00 iffitintercept False
niter array or None shape ntargets Actual number of iterations for each target Avail able only for sag and lsqr solvers Other solvers will return None
New in version 017

normalizeFalse randomstateNone solverauto tol0001
Methods
fitself X y sampleweight Fit Ridge regression model
getparams self deep Get parameters for this estimator
predict self X Predict using the linear model
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfalpha10 fitinterceptTrue normalizeFalse copyXTrue maxiterNone
tol0001 solver'auto' randomstateNone
fitselfXysampleweightNone
Fit Ridge regression model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data
yarraylike shape nsamples or nsamples ntargets Target values
sampleweight float or numpy array of shape nsamples Individual weights for each
sample
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples

Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnlinearmodelRidge
•Compressive sensing tomography reconstruction with L1 prior Lasso
•Prediction Latency
•Plot Ridge coefficients as a function of the regularization

Linear classifiers SVM logistic regression ao with SGD training
This estimator implements regularized linear models with stochastic gradient descent SGD learning the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule aka learning rate SGD allows minibatch onlineoutofcore learning see the partialfit method For best results using the default learning rate schedule the data should have zero mean and unit variance
This implementation works with data represented as dense or sparse arrays of floating point values for the features The model it fits can be controlled with the loss parameter by default it fits a linear support vector machine SVM
The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both Elastic Net If the parameter update crosses the 00 value because of the regularizer the update is truncated to 00 to allow for learning sparse models and achieve online feature selection
Read more in the User Guide
Parameters
loss str default ‘hinge’ The loss function to be used Defaults to ‘hinge’ which gives a linear SVM
The possible options are ‘hinge’ ‘log’ ‘modifiedhuber’ ‘squaredhinge’ ‘perceptron’ or a regression loss ‘squaredloss’ ‘huber’ ‘epsiloninsensitive’ or ‘squaredepsiloninsensitive’

The ‘log’ loss gives logistic regression a probabilistic classifier ‘modifiedhuber’ is another smooth loss that brings tolerance to outliers as well as probability estimates ‘squaredhinge’ is like hinge but is quadratically penalized ‘perceptron’ is the linear loss used by the perceptron algorithm The other losses are designed for regression but can be useful in classification as well see SGDRegressor for a description
penalty str ‘none’ ‘l2’ ‘l1’ or ‘elasticnet’ The penalty aka regularization term to be used Defaults to ‘l2’ which is the standard regularizer for linear SVM models ‘l1’ and ‘elasticnet’ might bring sparsity to the model feature selection not achievable with ‘l2’
alpha float Constant that multiplies the regularization term Defaults to 00001 Also used to compute learningrate when set to ‘optimal’
l1ratio float The Elastic Net mixing parameter with 0 l1ratio 1 l1ratio0 corresponds to L2 penalty l1ratio1 to L1 Defaults to 015
fitintercept bool Whether the intercept should be estimated or not If False the data is assumed to be already centered Defaults to True
maxiter int optional default1000 The maximum number of passes over the training data aka epochs It only impacts the behavior in the fit method and not the partialfit New in version 019
tolfloat or None optional default1e3 The stopping criterion If it is not None the iterations will stop when loss bestloss tol for niternochange consecutive epochs New in version 019
shuffle bool optional Whether or not the training data should be shuffled after each epoch Defaults to True
verbose integer optional The verbosity level
epsilon float Epsilon in the epsiloninsensitive loss functions only if loss is ‘huber’ ‘epsiloninsensitive’ or ‘squaredepsiloninsensitive’ For ‘huber’ determines the threshold at which it becomes less important to get the prediction exactly right For epsilon insensitive any differences between the current prediction and the correct label are ignored if they are less than this threshold
njobs int or None optional defaultNone The number of CPUs to use to do the OV A One Versus All for multiclass problems computation None means 1 unless in a joblib parallelbackend context1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
learningrate string optional The learning rate schedule
‘constant’ eta eta0
‘optimal’ default eta 10 alpha t t0 where t0 is chosen by a heuristic proposed by Leon Bottou
‘invscaling’ eta eta0 powt powert
‘adaptive’ eta eta0 as long as the training keeps decreasing Each time niternochange consecutive epochs fail to decrease the training loss by tol or fail to

increase validation score by tol if earlystopping is True the current learning rate is di
vided by 5
eta0 double The initial learning rate for the ‘constant’ ‘invscaling’ or ‘adaptive’ schedules
The default value is 00 as eta0 is not used by the default schedule ‘optimal’
powert double The exponent for inverse scaling learning rate default 05
earlystopping bool defaultFalse Whether to use early stopping to terminate training when
validation score is not improving If set to True it will automatically set aside a stratified
fraction of training data as validation and terminate training when validation score is not
improving by at least tol for niternochange consecutive epochs
New in version 020
validationfraction float default01 The proportion of training data to set aside as validation
set for early stopping Must be between 0 and 1 Only used if earlystopping is True
New in version 020
niternochange int default5 Number of iterations with no improvement to wait before
early stopping
New in version 020
classweight dict classlabel weight or “balanced” or None optional Preset for the
classweight fit parameter
Weights associated with classes If not given all classes are supposed to have weight one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
Repeatedly calling fit or partialfit when warmstart is True can result in a different solution
than when calling fit a single time because of the way the data is shuffled If a dynamic
learning rate is used the learning rate is adapted depending on the number of samples al
ready seen Calling fit resets this counter while partialfit will result in increasing
the existing counter
average bool or int optional When set to True computes the averaged SGD weights and
stores the result in the coef attribute If set to an int greater than 1 averaging will be
gin once the total number of samples seen reaches average So average10 will begin
averaging after seeing 10 samples
Attributes
coef array shape 1 nfeatures if nclasses 2 else nclasses nfeatures Weights as
signed to the features
intercept array shape 1 if nclasses 2 else nclasses Constants in decision function
niter int The actual number of iterations to reach the stopping criterion For multiclass fits
it is the maximum over every binary fit

erageFalse
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted

densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXycoefinitNone interceptinitNone sampleweightNone
Fit linear model with Stochastic Gradient Descent
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data
ynumpy array shape nsamples Target values
coefinit array shape nclasses nfeatures The initial coefficients to warmstart the op
timization
interceptinit array shape nclasses The initial intercept to warmstart the optimiza
tion
sampleweight arraylike shape nsamples optional Weights applied to individual
samples If not provided uniform weights are assumed These weights will be multiplied
with classweight passed through the constructor if classweight is specified
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone sampleweightNone
Perform one epoch of stochastic gradient descent on given samples
Internally this method uses maxiter 1 Therefore it is not guaranteed that a minimum of the cost
function is reached after calling it once Matters such as objective convergence and early stopping should
be handled by the user
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Subset of the training data
ynumpy array shape nsamples Subset of the target values
classes array shape nclasses Classes across all calls to partialfit Can be obtained by
vianpuniqueyall where yall is the target vector of the entire dataset This
argument is required for the first call to partialfit and can be omitted in the subsequent
calls Note that y doesn’t need to contain all labels in classes
sampleweight arraylike shape nsamples optional Weights applied to individual
samples If not provided uniform weights are assumed

Returns
self returns an instance of self
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
predictlogproba
Log of probability estimates
This method is only available for log loss and modified Huber loss
When loss”modifiedhuber” probability estimates may be hard zeros and ones so taking the logarithm is not possible
Seepredictproba for details
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tarraylike shape nsamples nclasses Returns the logprobability of the sample for each class in the model where classes are ordered as they are in selfclasses
predictproba
Probability estimates
This method is only available for log loss and modified Huber loss
Multiclass probability estimates are derived from binary onevsrest estimates by simple normalization as recommended by Zadrozny and Elkan
Binary probability estimates for loss”modifiedhuber” are given by clipdecisionfunctionX 1 1 1 2 For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with sklearncalibrationCalibratedClassifierCV instead
Parameters
Xarraylike sparse matrix shape nsamples nfeatures
Returns
array shape nsamples nclasses Returns the probability of the sample for each class in the model where classes are ordered as they are in selfclasses
References
Zadrozny and Elkan “Transforming classifier scores into multiclass probability estimates” SIGKDD‘02 httpwwwresearchibmcompeoplezzadroznykdd2002Transfpdf
The justification for the formula in the loss”modifiedhuber” case is in the appendix B in httpjmlr csailmitedupapersvolume2zhang02czhang02cpdf

scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
Examples using sklearnlinearmodelSGDClassifier
•Model Complexity Influence
•Outofcore classification of text documents
•Pipelining chaining a PCA and a logistic regression
•SGD Maximum margin separating hyperplane
•SGD Weighted samples
•Comparing various online solvers
•Plot multiclass SGD on the iris dataset
•Early stopping of Stochastic Gradient Descent
•Sample pipeline for text feature extraction and evaluation
•Classification of text documents using sparse features

62220sklearnlinearmodel SGDRegressor
classsklearnlinearmodel SGDRegressor loss’squaredloss’ penalty’l2’ alpha00001
l1ratio015 fitinterceptTrue maxiter1000
tol0001 shuffleTrue verbose0 epsilon01
randomstateNone learningrate’invscaling’
eta0001 powert025 earlystoppingFalse
validationfraction01 niternochange5
warmstartFalse averageFalse
Linear model fitted by minimizing a regularized empirical loss with SGD
SGD stands for Stochastic Gradient Descent the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule aka learning rate
The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both Elastic Net If the parameter update crosses the 00 value because of the regularizer the update is truncated to 00 to allow for learning sparse models and achieve online feature selection
This implementation works with data represented as dense numpy arrays of floating point values for the features
Read more in the User Guide
Parameters
loss str default ‘squaredloss’ The loss function to be used The possible values are ‘squaredloss’ ‘huber’ ‘epsiloninsensitive’ or ‘squaredepsiloninsensitive’
The ‘squaredloss’ refers to the ordinary least squares fit ‘huber’ modifies ‘squaredloss’ to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon ‘epsiloninsensitive’ ignores errors less than epsilon and is linear past that this is the loss function used in SVR ‘squaredepsiloninsensitive’ is the same but becomes squared loss past a tolerance of epsilon
penalty str ‘none’ ‘l2’ ‘l1’ or ‘elasticnet’ The penalty aka regularization term to be used Defaults to ‘l2’ which is the standard regularizer for linear SVM models ‘l1’ and ‘elasticnet’ might bring sparsity to the model feature selection not achievable with ‘l2’
alpha float Constant that multiplies the regularization term Defaults to 00001 Also used to compute learningrate when set to ‘optimal’
l1ratio float The Elastic Net mixing parameter with 0 l1ratio 1 l1ratio0 corresponds to L2 penalty l1ratio1 to L1 Defaults to 015
fitintercept bool Whether the intercept should be estimated or not If False the data is assumed to be already centered Defaults to True
maxiter int optional default1000 The maximum number of passes over the training data aka epochs It only impacts the behavior in the fit method and not the partialfit
New in version 019
tolfloat or None optional default1e3 The stopping criterion If it is not None the iterations will stop when loss bestloss tol for niternochange consecutive epochs
New in version 019
shuffle bool optional Whether or not the training data should be shuffled after each epoch Defaults to True
verbose integer optional The verbosity level

epsilon float Epsilon in the epsiloninsensitive loss functions only if loss is ‘huber’ ‘ep
siloninsensitive’ or ‘squaredepsiloninsensitive’ For ‘huber’ determines the thresh
old at which it becomes less important to get the prediction exactly right For epsilon
insensitive any differences between the current prediction and the correct label are ignored
if they are less than this threshold
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator to use when shuffling the data If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
learningrate string optional The learning rate schedule
‘constant’ eta eta0
‘optimal’ eta 10 alpha t t0 where t0 is chosen by a heuristic proposed by Leon
Bottou
‘invscaling’ default eta eta0 powt powert
‘adaptive’ eta eta0 as long as the training keeps decreasing Each time
niternochange consecutive epochs fail to decrease the training loss by tol or fail to
increase validation score by tol if earlystopping is True the current learning rate is di
vided by 5
eta0 double The initial learning rate for the ‘constant’ ‘invscaling’ or ‘adaptive’ schedules
The default value is 001
powert double The exponent for inverse scaling learning rate default 05
earlystopping bool defaultFalse Whether to use early stopping to terminate training when
validation score is not improving If set to True it will automatically set aside a fraction of
training data as validation and terminate training when validation score is not improving by
at least tol for niternochange consecutive epochs
New in version 020
validationfraction float default01 The proportion of training data to set aside as validation
set for early stopping Must be between 0 and 1 Only used if earlystopping is True
New in version 020
niternochange int default5 Number of iterations with no improvement to wait before
early stopping
New in version 020
warmstart bool optional When set to True reuse the solution of the previous call to fit as
initialization otherwise just erase the previous solution See the Glossary
Repeatedly calling fit or partialfit when warmstart is True can result in a different solution
than when calling fit a single time because of the way the data is shuffled If a dynamic
learning rate is used the learning rate is adapted depending on the number of samples al
ready seen Calling fit resets this counter while partialfit will result in increasing
the existing counter
average bool or int optional When set to True computes the averaged SGD weights and
stores the result in the coef attribute If set to an int greater than 1 averaging will be
gin once the total number of samples seen reaches average So average10 will begin
averaging after seeing 10 samples
Attributes

coef array shape nfeatures Weights assigned to the features
intercept array shape 1 The intercept term
averagecoef array shape nfeatures Averaged weights assigned to the features
averageintercept array shape 1 The averaged intercept term
niter int The actual number of iterations to reach the stopping criterion

densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified

otherwise it is a noop
Returns
self estimator
fitselfXycoefinitNone interceptinitNone sampleweightNone
Fit linear model with Stochastic Gradient Descent
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data
ynumpy array shape nsamples Target values
coefinit array shape nfeatures The initial coefficients to warmstart the optimization
interceptinit array shape 1 The initial intercept to warmstart the optimization
sampleweight arraylike shape nsamples optional Weights applied to individual
samples 1 for unweighted
Returns
self returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXysampleweightNone
Perform one epoch of stochastic gradient descent on given samples
Internally this method uses maxiter 1 Therefore it is not guaranteed that a minimum of the cost
function is reached after calling it once Matters such as objective convergence and early stopping should
be handled by the user
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Subset of training data
ynumpy array of shape nsamples Subset of target values
sampleweight arraylike shape nsamples optional Weights applied to individual
samples If not provided uniform weights are assumed
Returns
self returns an instance of self
predictselfX
Predict using the linear model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures
Returns
array shape nsamples Predicted target values per element in X

scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more
memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory
usage so use this method with care A rule of thumb is that the number of zero elements which can be
computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call
densify
Examples using sklearnlinearmodelSGDRegressor
•Prediction Latency

62221sklearnlinearmodel TheilSenRegressor
classsklearnlinearmodel TheilSenRegressor fitinterceptTrue copyXTrue
maxsubpopulation100000
nsubsamplesNone maxiter300
tol0001 randomstateNone
njobsNone verboseFalse
TheilSen Estimator robust multivariate regression model
The algorithm calculates least square solutions on subsets with size nsubsamples of the samples in X Any value of nsubsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency Since the number of least square solutions is “nsamples choose nsubsamples” it can be extremely large and can therefore be limited with maxsubpopulation If this limit is reached the subsets are chosen randomly In a final step the spatial median or L1 median is calculated of all least square solutions
Read more in the User Guide
Parameters
fitintercept boolean optional default True Whether to calculate the intercept for this model If set to false no intercept will be used in calculations
copyX boolean optional default True If True X will be copied else it may be overwritten
maxsubpopulation int optional default 1e4 Instead of computing with a set of cardinality ‘n choose k’ where n is the number of samples and k is the number of subsamples at least number of features consider only a stochastic subpopulation of a given maximal size if ‘n choose k’ is larger than maxsubpopulation For other than small problem sizes this parameter will determine memory usage and runtime if nsubsamples is not changed
nsubsamples int optional default None Number of samples to calculate the parameters This is at least the number of features plus 1 if fitinterceptTrue and the number of sam ples as a maximum A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency If None take the minimum number of subsamples leading to maximal robustness If nsubsamples is set to nsamples TheilSen is identical to least squares
maxiter int optional default 300 Maximum number of iterations for the calculation of spa tial median
tolfloat optional default 1e3 Tolerance when calculating spatial median
randomstate int RandomState instance or None optional default None A random number generator instance to define the state of the random permutations generator If int ran domstate is the seed used by the random number generator If RandomState instance ran domstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
njobs int or None optional defaultNone Number of CPUs to use during the cross valida tionNone means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
verbose boolean optional default False Verbose mode when fitting the model
Attributes
coef array shape nfeatures Coefficients of the regression model median of distribution
intercept float Estimated intercept of regression model
breakdown float Approximated breakdown point
niter int Number of iterations needed for the spatial median

nsubpopulation int Number of combinations taken into account from ‘n choose k’ where
n is the number of samples and k is the number of subsamples

returnpath bool optional defaultTrue If returnpathTrue returns the entire path else returns only the last point of the path
returnniter bool optional defaultFalse Whether to return the number of iterations
positive boolean defaultFalse Restrict coefficients to be 0 This option is only allowed with method ‘lasso’ Note that the model coefficients will not converge to the ordinary leastsquares solution for small values of alpha Only coefficients up to the smallest alpha value alphasalphas 0min when fitpathTrue reached by the step wise LarsLasso algorithm are typically in congruence with the solution of the coordinate descent lassopath function
Returns
alphas array shape nalphas 1 Maximum of covariances in absolute value at each iteration nalphas is eithermaxiter nfeatures or the number of nodes in the path withalpha alphamin whichever is smaller
active array shape nalphas Indices of active variables at the end of the path
coefs array shape nfeatures nalphas 1 Coefficients along the path
niter int Number of iterations run Returned only if returnniter is set to True

Compute Lasso path with coordinate descent
The Lasso optimization function varies for mono and multioutputs
For monooutput tasks it is
1 2 nsamples y Xw22 alpha w1
For multioutput tasks it is
1 2 nsamples Y XW2Fro alpha W21
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training data Pass directly as
Fortrancontiguous data to avoid unnecessary memory duplication If yis monooutput then
Xcan be sparse
yndarray shape nsamples or nsamples noutputs Target values
eps float optional Length of the path eps1e3 means thatalphamin alphamax
 1e3
nalphas int optional Number of alphas along the regularization path
alphas ndarray optional List of alphas where to compute the models If None alphas are set
automatically
precompute True False 'auto' arraylike Whether to use a precomputed Gram matrix to
speed up calculations If set to auto let us decide The Gram matrix can also be passed
as argument
Xyarraylike optional Xy npdotXT y that can be precomputed It is useful only when
the Gram matrix is precomputed
copyX boolean optional default True If True X will be copied else it may be overwritten
coefinit array shape nfeatures None The initial values of the coefficients
verbose bool or integer Amount of verbosity
returnniter bool whether to return the number of iterations or not

positive bool default False If set to True forces coefficients to be positive Only allowed
whenyndim 1
params kwargs keyword arguments passed to the coordinate descent solver
Returns
alphas array shape nalphas The alphas along the path where models are computed
coefs array shape nfeatures nalphas or noutputs nfeatures nalphas Coefficients
along the path
dualgaps array shape nalphas The dual gaps at the end of the optimization for each
alpha
niters arraylike shape nalphas The number of iterations taken by the coordinate descent
optimizer to reach the specified tolerance for each alpha

Parameters
Xarraylike sparse matrix LinearOperator shape nsamples nfeatures Training data
yarraylike shape nsamples or nsamples ntargets Target values
alpha float arraylike shape ntargets if arraylike Regularization strength must be
a positive float Regularization improves the conditioning of the problem and reduces the
variance of the estimates Larger values specify stronger regularization Alpha corresponds
toC1 in other linear models such as LogisticRegression or LinearSVC If an array is
passed penalties are assumed to be specific to the targets Hence they must correspond in
number
sampleweight float or numpy array of shape nsamples Individual weights for each sam
ple If sampleweight is not None and solver'auto' the solver will be set to 'cholesky'
New in version 017
solver 'auto' 'svd' 'cholesky' 'lsqr' 'sparsecg' 'sag' 'saga' Solver to use in the com
putational routines
• 'auto' chooses the solver automatically based on the type of data
• 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients More
stable for singular matrices than 'cholesky'

• ‘cholesky’ uses the standard scipylinalgsolve function to obtain a closedform solution via a Cholesky decomposition of dotXT X
• ‘sparsecg’ uses the conjugate gradient solver as found in scipysparselinalgcg As an iterative algorithm this solver is more appropriate than ‘cholesky’ for largescale data possibility to set tol andmaxiter
• ‘lsqr’ uses the dedicated regularized leastsquares routine scipysparselinalglsqr It is the fastest and uses an iterative procedure
• ‘sag’ uses a Stochastic Average Gradient descent and ‘saga’ uses its improved unbiased version named SAGA Both methods also use an iterative procedure and are often faster than other solvers when both nsamples and nfeatures are large Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale You can preprocess the data with a scaler from sklearnpreprocessing
All last five solvers support both dense and sparse data However only ‘sag’ and ‘sparsecg’ supports sparse input when‘fitintercept‘ is True
New in version 017 Stochastic Average Gradient descent solver
New in version 019 SAGA solver
maxiter int optional Maximum number of iterations for conjugate gradient solver For the ‘sparsecg’ and ‘lsqr’ solvers the default value is determined by scipysparselinalg For ‘sag’ and saga solver the default value is 1000
tolfloat Precision of the solution
verbose int Verbosity level Setting verbose 0 will display additional information depending on the solver used
randomstate int RandomState instance or None optional default None The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when solver ‘sag’
returnniter boolean default False If True the method also returns niter the actual number of iteration performed by the solver
New in version 017
returnintercept boolean default False If True and if X is sparse the method also re turns the intercept and the solver is automatically changed to ‘sag’ This is only a temporary fix for fitting the intercept with sparse data For dense data use sklearnlinearmodelpreprocessdata before your regression
New in version 017
checkinput boolean default True If False the input arrays X and y will not be checked
New in version 021
Returns
coef array shape nfeatures or ntargets nfeatures Weight vectors
niter int optional The actual number of iteration performed by the solver Only returned if returnniter is True
intercept float or array shape ntargets The intercept of the model Only returned if returnintercept is True and if X is a scipy sparse array

Notes
This function won’t compute the intercept

reconstructionerror self
Compute the reconstruction error for the embedding
Returns
reconstructionerror float
Notes
The cost function of an isomap embedding is
E frobeniusnormKD KDfit nsamples
Where D is the matrix of distances for the input data X Dfit is the matrix of distances for the output
embedding Xfit and K is the isomap kernel
KD 05 I 1nsamples D2I 1nsamples
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform X

This is implemented by linking the points X into the graph of geodesic distances of the training data
First thenneighbors nearest neighbors of X are found in the training data and from these the shortest
geodesic distances from each point in X to each point in the training data are computed in order to construct
the kernel The embedding of X is the projection of this kernel onto the embedding vectors of the training
set
Parameters
Xarraylike shape nsamples nfeatures
Returns
Xnew arraylike shape nsamples ncomponents

scikitlearn user guide Release 0213
6234sklearnmanifold SpectralEmbedding
classsklearnmanifold SpectralEmbedding ncomponents2 affinity‘nearestneighbors’
gammaNone randomstateNone
eigensolverNone nneighborsNone
njobsNone
Spectral embedding for nonlinear dimensionality reduction
Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding
graph laplacian The resulting transformation is given by the value of the eigenvectors for each data point
Note Laplacian Eigenmaps is the actual algorithm implemented here
Read more in the User Guide
Parameters
ncomponents integer default 2 The dimension of the projected subspace
affinity string or callable default
How to construct the affinity matrix
• ‘nearestneighbors’ construct affinity matrix by knn graph
• ‘rbf’ construct affinity matrix by rbf kernel
• ‘precomputed’ interpret X as precomputed affinity matrix
• callable use passed in function as affinity the function takes in data matrix nsamples
nfeatures and return affinity matrix nsamples nsamples
gamma float optional default Kernel coefficient for rbf kernel
randomstate int RandomState instance or None optional default None A pseudo random
number generator used for the initialization of the lobpcg eigenvectors If int randomstate
is the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom Used when solver ‘amg’
eigensolver None ‘arpack’ ‘lobpcg’ or ‘amg’ The eigenvalue decomposition strategy to
use AMG requires pyamg to be installed It can be faster on very large sparse problems
but may also lead to instabilities
nneighbors int default Number of nearest neighbors for nearestneighbors graph building

tdistributed Stochastic Neighbor Embedding
tSNE 1 is a tool to visualize highdimensional data It converts similarities between data points to joint
probabilities and tries to minimize the KullbackLeibler divergence between the joint probabilities of the low
dimensional embedding and the highdimensional data tSNE has a cost function that is not convex ie with
different initializations we can get different results
It is highly recommended to use another dimensionality reduction method eg PCA for dense data or Truncat
edSVD for sparse data to reduce the number of dimensions to a reasonable amount eg 50 if the number of
features is very high This will suppress some noise and speed up the computation of pairwise distances between
samples For more tips see Laurens van der Maaten’s FAQ 2
Read more in the User Guide
Parameters
ncomponents int optional default 2 Dimension of the embedded space
perplexity float optional default 30 The perplexity is related to the number of nearest
neighbors that is used in other manifold learning algorithms Larger datasets usually require
a larger perplexity Consider selecting a value between 5 and 50 Different values can result
in significanlty different results

earlyexaggeration float optional default 120 Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them For larger values the space between natural clusters will be larger in the embedded space Again the choice of this parameter is not very critical If the cost function increases during initial optimization the early exaggeration factor or the learning rate might be too high
learningrate float optional default 2000 The learning rate for tSNE is usually in the range 100 10000 If the learning rate is too high the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours If the learning rate is too low most points may look compressed in a dense cloud with few outliers If the cost function gets stuck in a bad local minimum increasing the learning rate may help
niter int optional default 1000 Maximum number of iterations for the optimization Should be at least 250
niterwithoutprogress int optional default 300 Maximum number of iterations without progress before we abort the optimization used after 250 initial iterations with early exag geration Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50
New in version 017 parameter niterwithoutprogress to control stopping criteria
mingradnorm float optional default 1e7 If the gradient norm is below this threshold the optimization will be stopped
metric string or callable optional The metric to use when calculating distance between instances in a feature array If metric is a string it must be one of the options al lowed by scipyspatialdistancepdist for its metric parameter or a metric listed in pair wisePAIRWISEDISTANCEFUNCTIONS If metric is “precomputed” X is assumed to be a distance matrix Alternatively if metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays from X as input and return a value indicating the distance between them The default is “euclidean” which is interpreted as squared euclidean distance
init string or numpy array optional default “random” Initialization of embedding Possible options are ‘random’ ‘pca’ and a numpy array of shape nsamples ncomponents PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization
verbose int optional default 0 Verbosity level
randomstate int RandomState instance or None optional default None If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Note that different initializations might result in different local minima of the cost function
method string default ‘barneshut’ By default the gradient calculation algorithm uses BarnesHut approximation running in ONlogN time method’exact’ will run on the slower but exact algorithm in ON2 time The exact algorithm should be used when nearestneighbor errors need to be better than 3 However the exact method cannot scale to millions of examples
New in version 017 Approximate optimization method via the BarnesHut
angle float default 05 Only used if method’barneshut’ This is the tradeoff between speed and accuracy for BarnesHut TSNE ‘angle’ is the angular size referred to as theta in 3 of a distant node as measured from a point If this size is below ‘angle’ then it is used as a summary node of all points contained within it This method is not very sensitive to

changes in this parameter in the range of 02 08 Angle less than 02 has quickly increasing computation time and angle greater 08 has quickly increasing error
Attributes
embedding arraylike shape nsamples ncomponents Stores the embedding vectors
kldivergence float KullbackLeibler divergence after optimization
niter int Number of iterations run

fitselfXyNone
Fit X into an embedded space
Parameters
Xarray shape nsamples nfeatures or nsamples nsamples If the metric is ‘precomputed’ X must be a square distance matrix Otherwise it contains a sample per row If the method is ‘exact’ X may be a sparse matrix of type ‘csr’ ‘csc’ or ‘coo’
ylgnored
fittransform selfXyNone
Fit X into an embedded space and return that transformed output

Parameters
Xarray shape nsamples nfeatures or nsamples nsamples If the metric is ‘pre
computed’ X must be a square distance matrix Otherwise it contains a sample per row
yIgnored
Returns
Xnew array shape nsamples ncomponents Embedding of the training data in low
dimensional space
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Parameters
Xarraylike NearestNeighbors Sample data shape nsamples nfeatures in the form
of a numpy array or a NearestNeighbors object
nneighbors integer number of neighbors to consider for each point
ncomponents integer number of coordinates for the manifold
regfloat regularization constant multiplies the trace of the local covariance matrix of the
distances
eigensolver string ‘auto’ ‘arpack’ ‘dense’ auto algorithm will attempt to choose the
best method for input data
arpack use arnoldi iteration in shiftinvert mode For this method M may be a dense
matrix sparse matrix or general linear operator Warning ARPACK can be unstable for
some problems It is best to try several random seeds in order to check results
dense use standard dense matrix operations for the eigenvalue decomposition For this
method M must be an array or matrix type This method should be avoided for large
problems
tolfloat optional Tolerance for ‘arpack’ method Not used if eigensolver’dense’
maxiter integer maximum number of iterations for the arpack solver
method ‘standard’ ‘hessian’ ‘modified’ ‘ltsa’
standard use the standard locally linear embedding algorithm see reference 1
hessian use the Hessian eigenmap method This method requires nneighbors
ncomponents 1 ncomponents 1 2 see reference 2
modified use the modified locally linear embedding algorithm see reference 3
ltsa use local tangent space alignment algorithm see reference 4
hessiantol float optional Tolerance for Hessian eigenmapping method Only used if method
 ‘hessian’
modifiedtol float optional Tolerance for modified LLE method Only used if method
‘modified’
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when solver ‘arpack’
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details
Returns
Yarraylike shape nsamples ncomponents Embedding vectors
squarederror float Reconstruction error for the embedding vectors Equivalent to normY
 W Y fro 2 where W are the reconstruction weights

njobsNone maxiter300 verbose0 eps0001 randomstateNone
returnniterFalse
Computes multidimensional scaling using the SMACOF algorithm
The SMACOF Scaling by MAjorizing a COmplicated Function algorithm is a multidimensional scaling algo
rithm which minimizes an objective function the stress using a majorization technique Stress majorization
also known as the Guttman Transform guarantees a monotone convergence of stress and is more powerful than
traditional techniques such as gradient descent
The SMACOF algorithm for metric MDS can summarized by the following steps
1 Set an initial start configuration randomly or not
2 Compute the stress
3 Compute the Guttman Transform
4 Iterate 2 and 3 until convergence
The nonmetric algorithm adds a monotonic regression step before computing the stress
Parameters
dissimilarities ndarray shape nsamples nsamples Pairwise dissimilarities between the
points Must be symmetric
metric boolean optional default True Compute metric or nonmetric SMACOF algorithm
ncomponents int optional default 2 Number of dimensions in which to immerse the dis
similarities If an init array is provided this option is overridden and the shape of init
is used to determine the dimensionality of the embedding space
init ndarray shape nsamples ncomponents optional default None Starting configura
tion of the embedding to initialize the algorithm By default the algorithm is initialized
with a randomly chosen array
ninit int optional default 8 Number of times the SMACOF algorithm will be run with
different initializations The final results will be the best output of the runs determined by
the run with the smallest final stress If init is provided this option is overridden and a
single run is performed
njobs int or None optional defaultNone The number of jobs to use for the computation
If multiple initializations are used ninit each run of the algorithm is computed in
parallel
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details

maxiter int optional default 300 Maximum number of iterations of the SMACOF algo
rithm for a single run
verbose int optional default 0 Level of verbosity
eps float optional default 1e3 Relative tolerance with respect to stress at which to declare
convergence
randomstate int RandomState instance or None optional default None The generator
used to initialize the centers If int randomstate is the seed used by the random number
generator If RandomState instance randomstate is the random number generator If None
the random number generator is the RandomState instance used by nprandom
returnniter bool optional default False Whether or not to return the number of iterations
Returns
Xndarray shape nsamples ncomponents Coordinates of the points in a
ncomponents space
stress float The final value of the stress sum of squared distance of the disparities and the
distances for all constrained points
niter int The number of iterations corresponding to the best stress Returned only if
returnniter is set toTrue

6238sklearnmanifold spectralembedding
sklearnmanifold spectralembedding adjacency ncomponents8 eigensolverNone ran
domstateNone eigentol00 normlaplacianTrue
dropfirstTrue
Project the sample on the first eigenvectors of the graph Laplacian
The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum especially the eigen
vectors associated to the smallest eigenvalues has an interpretation in terms of minimal number of cuts neces
sary to split the graph into comparably sized components
This embedding can also ‘work’ even if the adjacency variable is not strictly the adjacency matrix of a graph
but more generally an affinity or similarity matrix between samples for instance the heat kernel of a euclidean
distance matrix or a kNN matrix
However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition
works as expected
Note Laplacian Eigenmaps is the actual algorithm implemented here
Read more in the User Guide
Parameters

adjacency arraylike or sparse matrix shape nsamples nsamples The adjacency matrix
of the graph to embed
ncomponents integer optional default 8 The dimension of the projection subspace
eigensolver None ‘arpack’ ‘lobpcg’ or ‘amg’ default None The eigenvalue decompo
sition strategy to use AMG requires pyamg to be installed It can be faster on very large
sparse problems but may also lead to instabilities
randomstate int RandomState instance or None optional default None A pseudo random
number generator used for the initialization of the lobpcg eigenvectors decomposition If int
randomstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is the
RandomState instance used by nprandom Used when solver ‘amg’
eigentol float optional default00 Stopping criterion for eigendecomposition of the Lapla
cian matrix when using arpack eigensolver
normlaplacian bool optional defaultTrue If True then compute normalized Laplacian
dropfirst bool optional defaultTrue Whether to drop the first eigenvector For spectral em
bedding this should be True as the first eigenvector should be constant vector for connected
graph but for spectral clustering this should be kept as False to retain the first eigenvector
Returns
embedding array shapensamples ncomponents The reduced samples
Notes
Spectral Embedding Laplacian Eigenmaps is most useful when the graph has one connected component If
there graph has many components the first few eigenvectors will simply uncover the connected components of
the graph

sklearnmetrics checkscoring
sklearnmetrics checkscoring estimator scoringNone allownoneFalse
Determine scorer from user options
A TypeError will be thrown if the estimator cannot be scored
Parameters
estimator estimator object implementing ‘fit’ The object to use to fit the data
scoring string callable or None optional default None A string see model evaluation doc
umentation or a scorer callable object function with signature scorerestimator
X y
allownone boolean optional default False If no scoring is specified and the estimator has
no score function we can either return None or raise an exception
Returns
scoring callable A scorer callable object function with signature scorerestimator
X y
sklearnmetrics getscorer
sklearnmetrics getscorer scoring
Get a scorer from string
Parameters
scoring str callable scoring method as string If callable it is returned as is
Returns
scorer callable The scorer
sklearnmetrics makescorer
sklearnmetrics makescorer scorefunc greaterisbetterTrue needsprobaFalse
needsthresholdFalse kwargs
Make a scorer from a performance metric or loss function
This factory function wraps scoring functions for use in GridSearchCV and crossvalscore It takes
a score function such as accuracyscore meansquarederror adjustedrandindex or
averageprecision and returns a callable that scores an estimator’s output
Read more in the User Guide
Parameters
scorefunc callable Score function or loss function with signature scorefuncy
ypred kwargs
greaterisbetter boolean defaultTrue Whether scorefunc is a score function default
meaning high is good or a loss function meaning low is good In the latter case the scorer
object will signflip the outcome of the scorefunc

needsproba boolean defaultFalse Whether scorefunc requires predictproba to get prob
ability estimates out of a classifier
If True for binary ytrue the score function is supposed to accept a 1D ypred ie
probability of the positive class shape nsamples
needsthreshold boolean defaultFalse Whether scorefunc takes a continuous decision cer
tainty This only works for binary classification using estimators that have either a deci
sionfunction or predictproba method
If True for binary ytrue the score function is supposed to accept a 1D ypred ie
probability of the positive class or the decision function shape nsamples
For example averageprecision or the area under the roc curve can not be computed
using discrete predictions alone
kwargs additional arguments Additional parameters to be passed to scorefunc
Returns
scorer callable Callable object that returns a scalar score greater is better

sklearnmetrics accuracyscore
sklearnmetrics accuracyscore ytrue ypred normalizeTrue sampleweightNone
Accuracy classification score
In multilabel classification this function computes subset accuracy the set of labels predicted for a sample must exactly match the corresponding set of labels in ytrue
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct labels
ypred 1d arraylike or label indicator array sparse matrix Predicted labels as returned by a classifier
normalize bool optional defaultTrue If False return the number of correctly classified samples Otherwise return the fraction of correctly classified samples
sampleweight arraylike of shape nsamples optional Sample weights
Returns
score float Ifnormalize True return the fraction of correctly classified samples float else returns the number of correctly classified samples int
The best performance is 1 with normalize True and the number of samples with normalize False
See also
jaccardscore hammingloss zerooneloss

Notes
In binary and multiclass classification this function is equal to the jaccardscore function
Examples

sklearnmetrics auc
sklearnmetrics aucxyreorder'deprecated'
Compute Area Under the Curve AUC using the trapezoidal rule
This is a general function given points on a curve For computing the area under the ROC curve see rocaucscore For an alternative way to summarize a precisionrecall curve see averageprecisionscore
Parameters
xarray shape n x coordinates These must be either monotonic increasing or monotonic decreasing
yarray shape n y coordinates
reorder boolean optional default'deprecated' Whether to sort x before computing If False assume that x must be either monotonic increasing or monotonic decreasing If True y is used to break ties when sorting x Make sure that y has a monotonic relation to x when setting reorder to True
Deprecated since version 020 Parameter reorder has been deprecated in version 020 and will be removed in 022 It's introduced for rocaucscore not for general use and is

no longer used there What’s more the result from auc will be significantly influenced if
x is sorted unexpectedly due to slight floating point error See issue 9786 Future and
default behavior is equivalent to reorderFalse
Returns
auc float
See also
rocaucscore Compute the area under the ROC curve
averageprecisionscore Compute average precision from prediction scores
precisionrecallcurve Compute precisionrecall pairs for different probability thresholds
Examples
import numpy as np
from sklearn import metrics
y nparray1 1 2 2
pred nparray01 04 035 08
fpr tpr thresholds metricsroccurvey pred poslabel2
metricsaucfpr tpr

Examples using sklearnmetricsauc
•Species distribution modeling
•Receiver Operating Characteristic ROC with cross validation
•Receiver Operating Characteristic ROC
sklearnmetrics averageprecisionscore
sklearnmetrics averageprecisionscore ytrue yscore average’macro’ poslabel1
sampleweightNone
Compute average precision AP from prediction scores
AP summarizes a precisionrecall curve as the weighted mean of precisions achieved at each threshold with the
increase in recall from the previous threshold used as the weight
AP∑
□□□−□□−1□□
where □□and□□are the precision and recall at the nth threshold 1 This implementation is not interpolated
and is different from computing the area under the precisionrecall curve with the trapezoidal rule which uses
linear interpolation and can be too optimistic
Note this implementation is restricted to the binary classification task or multilabel classification task
Read more in the User Guide
Parameters
ytrue array shape nsamples or nsamples nclasses True binary labels or binary label
indicators

yscore array shape nsamples or nsamples nclasses Target scores can either be
probability estimates of the positive class confidence values or nonthresholded measure
of decisions as returned by “decisionfunction” on some classifiers
average string None ‘micro’ ‘macro’ default ‘samples’ ‘weighted’ If None the scores
for each class are returned Otherwise this determines the type of averaging performed on
the data
micro Calculate metrics globally by considering each element of the label indicator
matrix as a label
macro Calculate metrics for each label and find their unweighted mean This does not
take label imbalance into account
weighted Calculate metrics for each label and find their average weighted by sup
port the number of true instances for each label
samples Calculate metrics for each instance and find their average
Will be ignored when ytrue is binary
poslabel int or str default1 The label of the positive class Only applied to binary
ytrue For multilabelindicator ytrue poslabel is fixed to 1
sampleweight arraylike of shape nsamples optional Sample weights
Returns
averageprecision float
See also
rocaucscore Compute the area under the ROC curve
precisionrecallcurve Compute precisionrecall pairs for different probability thresholds
Notes
Changed in version 019 Instead of linearly interpolating between operating points precisions are weighted by
the change in recall since the last operating point

Examples using sklearnmetricsaverageprecisionscore
•PrecisionRecall
sklearnmetrics balancedaccuracyscore
sklearnmetrics balancedaccuracyscore ytrue ypred sampleweightNone ad
justedFalse
Compute the balanced accuracy
The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets It is
defined as the average of recall obtained on each class
The best value is 1 and the worst value is 0 when adjustedFalse
Read more in the User Guide
Parameters
ytrue 1d arraylike Ground truth correct target values
ypred 1d arraylike Estimated targets as returned by a classifier
sampleweight arraylike of shape nsamples optional Sample weights
adjusted bool defaultFalse When true the result is adjusted for chance so that random
performance would score 0 and perfect performance scores 1
Returns
balancedaccuracy float
See also
recallscore rocaucscore
Notes
Some literature promotes alternative definitions of balanced accuracy Our definition is equivalent to
accuracyscore with classbalanced sample weights and shares desirable properties with the binary case
See the User Guide

0625

sklearnmetrics brierscoreloss
sklearnmetrics brierscoreloss ytrue yprob sampleweightNone poslabelNone
Compute the Brier score The smaller the Brier score the better hence the naming with “loss” Across all items in a set N predictions the Brier score measures the mean squared difference between 1 the predicted probability assigned to the possible outcomes for item i and 2 the actual outcome Therefore the lower the Brier score is for a set of predictions the better the predictions are calibrated Note that the Brier score always takes on a value between zero and one since this is the largest possible difference between a predicted probability which must be between zero and one and the actual outcome which can take on values of only 0 and 1 The Brier loss is composed of refinement loss and calibration loss The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false but is inappropriate for ordinal variables which can take on three or more values this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another Which label is considered to be the positive label is controlled via the parameter poslabel which defaults to 1 Read more in the User Guide
Parameters
ytrue array shape nsamples True targets
yprob array shape nsamples Probabilities of the positive class
sampleweight arraylike of shape nsamples optional Sample weights
poslabel int or str defaultNone Label of the positive class Defaults to the greater label unless ytrue is all 0 or all 1 in which case poslabel defaults to 1
Returns
score float Brier score

•Probability Calibration curves

scikitlearn user guide Release 0213
•Probability calibration of classifiers
sklearnmetrics classificationreport
sklearnmetrics classificationreport ytrue ypred labelsNone targetnamesNone
sampleweightNone digits2 outputdictFalse
Build a text report showing the main classification metrics
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct target values
ypred 1d arraylike or label indicator array sparse matrix Estimated targets as returned by a classifier
labels array shape nlabels Optional list of label indices to include in the report
targetnames list of strings Optional display names matching the labels same order
sampleweight arraylike of shape nsamples optional Sample weights
digits int Number of digits for formatting output floating point values When outputdict isTrue this will be ignored and the returned values will not be rounded
outputdict bool default False If True return output as dict
Returns
report string dict Text summary of the precision recall F1 score for each class Dictionary returned if outputdict is True Dictionary has the following structure
label 1 precision05
recall10
f1score067
support1
label 2

The reported averages include macro average averaging the unweighted mean per label weighted average averaging the supportweighted mean per label sample average only for multilabel classification and micro average averaging the to tal true positives false negatives and false positives it is only shown for multi label or multiclass with a subset of classes because it is accuracy otherwise See alsofuncprecisionrecallfscoresupport for more details on averages
Note that in binary classification recall of the positive class is also known as “sensitivity” recall of the negative class is “specificity”

sklearnmetrics cohenkappascore
sklearnmetrics cohenkappascore y1 y2 labelsNone weightsNone sam
pleweightNone
Cohen’s kappa a statistic that measures interannotator agreement
624sklearnmetrics Metrics 1993

This function computes Cohen’s kappa 1 a score that expresses the level of agreement between two annotators on a classification problem It is defined as
□ □□−□□1−□□
where □□is the empirical probability of agreement on the label assigned to any sample the observed agreement ratio and □□is the expected agreement when both annotators assign labels randomly □□is estimated using a perannotator empirical prior over the class labels 2
Read more in the User Guide
Parameters
y1array shape nsamples Labels assigned by the first annotator
y2array shape nsamples Labels assigned by the second annotator The kappa statistic is symmetric so swapping y1andy2doesn’t change the value
labels array shape nclasses optional List of labels to index the matrix This may be used to select a subset of labels If None all labels that appear at least once in y1ory2are used
weights str optional List of weighting type to calculate the score None means no weighted “linear” means linear weighted “quadratic” means quadratic weighted
sampleweight arraylike of shape nsamples optional Sample weights
Returns
kappa float The kappa statistic which is a number between 1 and 1 The maximum value means complete agreement zero or lower means chance agreement

sklearnmetrics f1score
sklearnmetrics f1score ytrue ypred labelsNone poslabel1 average'binary' sam
pleweightNone
Compute the F1 score also known as balanced Fscore or Fmeasure
The F1 score can be interpreted as a weighted average of the precision and recall where an F1 score reaches its
best value at 1 and worst score at 0 The relative contribution of precision and recall to the F1 score are equal
The formula for the F1 score is
F1 2precision recall precision recall
624sklearnmetrics Metrics 1995

In the multiclass and multilabel case this is the average of the F1 score of each class with weighting depending on theaverage parameter
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct target values
ypred 1d arraylike or label indicator array sparse matrix Estimated targets as returned by a classifier
labels list optional The set of labels to include when average binary and their order ifaverage is None Labels present in the data can be excluded for example to calculate a multiclass average ignoring a majority negative class while labels not present in the data will result in 0 components in a macro average For multilabel targets labels are column indices By default all labels in ytrue andypred are used in sorted order
Changed in version 017 parameter labels improved for multiclass problem
poslabel str or int 1 by default The class to report if averagebinary and the data is binary If the data are multiclass or multilabel this will be ignored setting labelsposlabel andaverage binary will report scores for that la bel only
average string None ‘binary’ default ‘micro’ ‘macro’ ‘samples’ ‘weighted’ This pa rameter is required for multiclassmultilabel targets If None the scores for each class are returned Otherwise this determines the type of averaging performed on the data
binary Only report results for the class specified by poslabel This is applicable only if targets ytruepred are binary
micro Calculate metrics globally by counting the total true positives false negatives and false positives
macro Calculate metrics for each label and find their unweighted mean This does not take label imbalance into account
weighted Calculate metrics for each label and find their average weighted by support the number of true instances for each label This alters ‘macro’ to account for label imbalance it can result in an Fscore that is not between precision and recall
samples Calculate metrics for each instance and find their average only meaningful for multilabel classification where this differs from accuracyscore
sampleweight arraylike of shape nsamples optional Sample weights
Returns
f1score float or array of float shape nuniquelabels F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task

sklearnmetrics hammingloss
sklearnmetrics hammingloss ytrue ypred labelsNone sampleweightNone
Compute the average Hamming loss
The Hamming loss is the fraction of labels that are incorrectly predicted
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct labels
ypred 1d arraylike or label indicator array sparse matrix Predicted labels as returned by
a classifier
labels array shape nlabels optional default’deprecated’ Integer array of labels If not
provided labels will be inferred from ytrue and ypred
New in version 018
Deprecated since version 021 This parameter labels is deprecated in version 021 and
will be removed in version 023 Hamming loss uses ytrueshape1 for the number
of labels when ytrue is binary label indicators so it is unnecessary for the user to specify
sampleweight arraylike of shape nsamples optional Sample weights
New in version 018
Returns
loss float or int Return the average Hamming loss between element of ytrue andypred
See also
accuracyscore jaccardscore zerooneloss
Notes
In multiclass classification the Hamming loss corresponds to the Hamming distance between ytrue and
ypred which is equivalent to the subset zerooneloss function when normalize parameter is set to
True
In multilabel classification the Hamming loss is different from the subset zeroone loss The zeroone loss
considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels
Hamming loss is more forgiving in that it penalizes only the individual labels
624sklearnmetrics Metrics 1999

The Hamming loss is upperbounded by the subset zeroone loss when normalize parameter is set to True It is always between 0 and 1 lower being better

Examples using sklearnmetricshammingloss

•Model Complexity Influence

sklearnmetrics hingeloss

sklearnmetrics hingeloss ytrue preddecision labelsNone sampleweightNone

Average hinge loss nonregularized

In binary class case assuming labels in ytrue are encoded with 1 and 1 when a prediction mistake is mademargin ytrue preddecision is always negative since the signs disagree implying 1 margin is always greater than 1 The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier

In multiclass case the function expects that either all the labels are included in ytrue or an optional labels argument is provided which contains all the labels The multilabel margin is calculated according to Crammer Singer’s method As in the binary case the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier

Read more in the User Guide

Parameters

ytrue array shape nsamples True target consisting of integers of two values The positive label must be greater than the negative label

preddecision array shape nsamples or nsamples nclasses Predicted decisions as output by decisionfunction floats

labels array optional default None Contains all the labels for the problem Used in multiclass hinge loss

sampleweight arraylike of shape nsamples optional Sample weights

sklearnmetrics multilabelconfusionmatrix
sklearnmetrics multilabelconfusionmatrix ytrue ypred sampleweightNone la
belsNone samplewiseFalse
Compute a confusion matrix for each class or sample
New in version 021
Compute classwise default or samplewise samplewiseTrue multilabel confusion matrix to evaluate the
accuracy of a classification and output confusion matrices for each class or sample
In multilabel confusion matrix □□□ the count of true negatives is □□□ 00 false negatives is □□□ 10
true positives is □□□ 11and false positives is □□□ 01
Multiclass data will be treated as if binarized under a onevsrest transformation Returned confusion matrices
will be in the order of sorted unique labels in the union of ytrue ypred
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix of shape nsamples noutputs
or nsamples Ground truth correct target values
ypred 1d arraylike or label indicator array sparse matrix of shape nsamples noutputs
or nsamples Estimated targets as returned by a classifier
624sklearnmetrics Metrics 2005

sampleweight arraylike of shape nsamples optional Sample weights
labels arraylike A list of classes or column indices to select some or to force inclusion of
classes absent from the data
samplewise bool defaultFalse In the multilabel case this calculates a confusion matrix per
sample
Returns
multiconfusion array shape noutputs 2 2 A 2x2 confusion matrix corresponding to each
output in the input When calculating classwise multiconfusion default then noutputs
 nlabels when calculating samplewise multiconfusion samplewiseTrue noutputs
 nsamples If labels is defined the results will be returned in the order specified in
labels otherwise the results will be returned in sorted order by default
See also
confusionmatrix
Notes
The multilabelconfusionmatrix calculates classwise or samplewise multilabel confusion matrices and in
multiclass tasks labels are binarized under a onevsrest way while confusionmatrix calculates one confusion
matrix for confusion between every two classes
Examples

•Probability Calibration curves

sklearnmetrics recallscore
sklearnmetrics recallscore ytrue ypred labelsNone poslabel1 average’binary’ sam
pleweightNone
Compute the recall
The recall is the ratio tp tp fn wheretpis the number of true positives and fnthe number of false
negatives The recall is intuitively the ability of the classifier to find all the positive samples
The best value is 1 and the worst value is 0
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct target
values
ypred 1d arraylike or label indicator array sparse matrix Estimated targets as returned by
a classifier
labels list optional The set of labels to include when average binary and their
order ifaverage is None Labels present in the data can be excluded for example to
calculate a multiclass average ignoring a majority negative class while labels not present in
the data will result in 0 components in a macro average For multilabel targets labels are
column indices By default all labels in ytrue andypred are used in sorted order
Changed in version 017 parameter labels improved for multiclass problem
poslabel str or int 1 by default The class to report if averagebinary and the
data is binary If the data are multiclass or multilabel this will be ignored setting
labelsposlabel andaverage binary will report scores for that la
bel only
average string None ‘binary’ default ‘micro’ ‘macro’ ‘samples’ ‘weighted’ This pa
rameter is required for multiclassmultilabel targets If None the scores for each class are
returned Otherwise this determines the type of averaging performed on the data
binary Only report results for the class specified by poslabel This is applicable
only if targets ytruepred are binary
micro Calculate metrics globally by counting the total true positives false negatives
and false positives
macro Calculate metrics for each label and find their unweighted mean This does not
take label imbalance into account
weighted Calculate metrics for each label and find their average weighted by support
the number of true instances for each label This alters ‘macro’ to account for label
imbalance it can result in an Fscore that is not between precision and recall
samples Calculate metrics for each instance and find their average only meaningful
for multilabel classification where this differs from accuracyscore
sampleweight arraylike of shape nsamples optional Sample weights
Returns
recall float if average is not None or array of float shape nuniquelabels Recall of the
positive class in binary classification or weighted average of the recall of each class for the
multiclass task

Examples using sklearnmetricsrecallscore
•Probability Calibration curves
sklearnmetrics rocaucscore
sklearnmetrics rocaucscore ytrue yscore average'macro' sampleweightNone
maxfprNone
Compute Area Under the Receiver Operating Characteristic Curve ROC AUC from prediction scores
Note this implementation is restricted to the binary classification task or multilabel classification task in label
indicator format
Read more in the User Guide
Parameters
ytrue array shape nsamples or nsamples nclasses True binary labels or binary label
indicators
yscore array shape nsamples or nsamples nclasses Target scores can either be
probability estimates of the positive class confidence values or nonthresholded measure
of decisions as returned by "decisionfunction" on some classifiers For binary ytrue
yscore is supposed to be the score of the class with greater label
average string None 'micro' 'macro' default 'samples' 'weighted' If None the scores
for each class are returned Otherwise this determines the type of averaging performed on
the data
micro Calculate metrics globally by considering each element of the label indicator
matrix as a label

macro Calculate metrics for each label and find their unweighted mean This does not
take label imbalance into account
weighted Calculate metrics for each label and find their average weighted by sup
port the number of true instances for each label
samples Calculate metrics for each instance and find their average
Will be ignored when ytrue is binary
sampleweight arraylike of shape nsamples optional Sample weights
maxfpr float 0 and 1 optional If not None the standardized partial AUC 3over the
range 0 maxfpr is returned
Returns
auc float

sklearnmetrics roccurve
sklearnmetrics roccurve ytrue yscore poslabelNone sampleweightNone
dropintermediateTrue
Compute Receiver operating characteristic ROC
Note this implementation is restricted to the binary classification task
Read more in the User Guide
Parameters
ytrue array shape nsamples True binary labels If labels are not either 1 1 or 0 1
then poslabel should be explicitly given
yscore array shape nsamples Target scores can either be probability estimates of the
positive class confidence values or nonthresholded measure of decisions as returned by
“decisionfunction” on some classifiers
poslabel int or str defaultNone The label of the positive class When poslabelNone
if ytrue is in 1 1 or 0 1 poslabel is set to 1 otherwise an error will be raised

sampleweight arraylike of shape nsamples optional Sample weights
dropintermediate boolean optional defaultTrue Whether to drop some suboptimal
thresholds which would not appear on a plotted ROC curve This is useful in order to
create lighter ROC curves
New in version 017 parameter dropintermediate
Returns
fprarray shape 2 Increasing false positive rates such that element i is the false positive
rate of predictions with score thresholdsi
tprarray shape 2 Increasing true positive rates such that element i is the true positive
rate of predictions with score thresholdsi
thresholds array shape nthresholds Decreasing thresholds on the decision function used
to compute fpr and tpr thresholds0 represents no instances being predicted and is
arbitrarily set to maxyscore 1
See also
rocaucscore Compute the area under the ROC curve
Notes
Since the thresholds are sorted from low to high values they are reversed upon returning them to ensure they
correspond to both fpr andtpr which are sorted in reversed order during their calculation

sklearnmetrics zerooneloss
sklearnmetrics zerooneloss ytrue ypred normalizeTrue sampleweightNone
Zeroone classification loss
If normalize is True return the fraction of misclassifications float else it returns the number of misclassifica
tions int The best performance is 0
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct labels
ypred 1d arraylike or label indicator array sparse matrix Predicted labels as returned by
a classifier
normalize bool optional defaultTrue If False return the number of misclassifications
Otherwise return the fraction of misclassifications
sampleweight arraylike of shape nsamples optional Sample weights
Returns
loss float or int If normalize True return the fraction of misclassifications float
else it returns the number of misclassifications int
See also
accuracyscore hammingloss jaccardscore
Notes
In multilabel classification the zerooneloss function corresponds to the subset zeroone loss for each sample
the entire set of labels must be correctly predicted otherwise the loss for that sample is equal to one
Examples
 from sklearnmetrics import zerooneloss
ypred 1 2 3 4
ytrue 2 2 3 4
zeroonelossytrue ypred
025
zeroonelossytrue ypred normalize False

•Effect of transforming the targets in regression model

scikitlearn user guide Release 0213
sklearnmetrics r2score
sklearnmetrics r2score ytrue ypred sampleweightNone multioutput’uniformaverage’
R2 coefficient of determination regression score function
Best possible score is 10 and it can be negative because the model can be arbitrarily worse A constant model
that always predicts the expected value of y disregarding the input features would get a R2 score of 00
Read more in the User Guide
Parameters
ytrue arraylike of shape nsamples or nsamples noutputs Ground truth correct
target values
ypred arraylike of shape nsamples or nsamples noutputs Estimated target values
sampleweight arraylike of shape nsamples optional Sample weights
multioutput string in ‘rawvalues’ ‘uniformaverage’ ‘varianceweighted’ or None or
arraylike of shape noutputs Defines aggregating of multiple output scores Arraylike
value defines weights used to average scores Default is “uniformaverage”
‘rawvalues’ Returns a full set of scores in case of multioutput input
‘uniformaverage’ Scores of all outputs are averaged with uniform weight
‘varianceweighted’ Scores of all outputs are averaged weighted by the variances of
each individual output
Changed in version 019 Default value of multioutput is ‘uniformaverage’
Returns
zfloat or ndarray of floats The R2 score or ndarray of scores if ‘multioutput’ is ‘rawvalues’
Notes
This is not a symmetric function
Unlike most other scores R2 score may be negative it need not actually be the square of a quantity R
This metric is not welldefined for single samples and will return a NaN value if nsamples is less than two

6244 Multilabel ranking metrics
See the Multilabel ranking metrics section of the user guide for further details
metricscoverageerror ytrue yscore Coverage error measure
metricslabelrankingaverageprecisionscore Compute rankingbased average precision
metricslabelrankingloss ytrue yscore Compute Ranking loss measure
sklearnmetrics coverageerror
sklearnmetrics coverageerror ytrue yscore sampleweightNone
Coverage error measure
Compute how far we need to go through the ranked scores to cover all true labels The best value is equal to the
average number of labels in ytrue per sample
Ties inyscores are broken by giving maximal rank that would have been assigned to all tied values
Note Our implementation’s score is 1 greater than the one given in Tsoumakas et al 2010 This extends it to
handle the degenerate case in which an instance has 0 true labels
Read more in the User Guide
Parameters
ytrue array shape nsamples nlabels True binary labels in binary indicator format
yscore array shape nsamples nlabels Target scores can either be probability esti
mates of the positive class confidence values or nonthresholded measure of decisions as
returned by “decisionfunction” on some classifiers
sampleweight arraylike of shape nsamples optional Sample weights
Returns

coverageerror float
References
1
sklearnmetrics labelrankingaverageprecisionscore
sklearnmetrics labelrankingaverageprecisionscore ytrue yscore sam
pleweightNone
Compute rankingbased average precision
Label ranking average precision LRAP is the average over each ground truth label assigned to each sample of the ratio of true vs total labels with lower score
This metric is used in multilabel ranking problem where the goal is to give better rank to the labels associated to each sample
The obtained score is always strictly greater than 0 and the best value is 1
Read more in the User Guide
Parameters
ytrue array or sparse matrix shape nsamples nlabels True binary labels in binary indicator format
yscore array shape nsamples nlabels Target scores can either be probability esti mates of the positive class confidence values or nonthresholded measure of decisions as returned by “decisionfunction” on some classifiers
sampleweight arraylike of shape nsamples optional Sample weights
Returns
score float
Examples
 import numpy as np
 from sklearnmetrics import labelrankingaverageprecisionscore
ytrue nparray1 0 0 0 0 1
yscore nparray075 05 1 1 02 01
labelrankingaverageprecisionscoreytrue yscore
0416
sklearnmetrics labelrankingloss
sklearnmetrics labelrankingloss ytrue yscore sampleweightNone
Compute Ranking loss measure
Compute the average number of label pairs that are incorrectly ordered given yscore weighted by the size of the label set and the number of labels not in the label set
This is similar to the error set size but weighted by the number of relevant and irrelevant labels The best performance is achieved with a ranking loss of zero

scikitlearn user guide Release 0213
Read more in the User Guide
New in version 017 A function labelrankingloss
Parameters
ytrue array or sparse matrix shape nsamples nlabels True binary labels in binary
indicator format
yscore array shape nsamples nlabels Target scores can either be probability esti
mates of the positive class confidence values or nonthresholded measure of decisions as
returned by “decisionfunction” on some classifiers
sampleweight arraylike of shape nsamples optional Sample weights
Returns
loss float

tween labels
metricsfowlkesmallowsscore labelstrue
   Measure the similarity of two clusterings of a set of points
metricshomogeneitycompletenessvmeasure   Compute the homogeneity and completeness and V
Measure scores at once
metricshomogeneityscore labelstrue   Homogeneity metric of a cluster labeling given a ground
truth
metricsmutualinfoscore labelstrue   Mutual Information between two clusterings
metricsnormalizedmutualinfoscore
   Normalized Mutual Information between two clusterings
metricssilhouettescore X labels   Compute the mean Silhouette Coefficient of all samples
metricssilhouettesamples X labels metric Compute the Silhouette Coefficient for each sample
metricsvmeasurescore labelstrue la
belspredVmeasure cluster labeling given a ground truth
624sklearnmetrics Metrics 2025

sklearnmetrics adjustedmutualinfoscore
sklearnmetrics adjustedmutualinfoscore labelstrue labelspred aver
agemethod'warn'
Adjusted Mutual Information between two clusterings
Adjusted Mutual Information AMI is an adjustment of the Mutual Information MI score to account for
chance It accounts for the fact that the MI is generally higher for two clusterings with a larger number of
clusters regardless of whether there is actually more information shared For two clusterings □and□ the AMI
is given as
AMIU V MIU V EMIU V avgHU HV EMIU V
This metric is independent of the absolute values of the labels a permutation of the class or cluster label values
won't change the score value in any way
This metric is furthermore symmetric switching labeltrue withlabelpred will return the same score
value This can be useful to measure the agreement of two independent label assignments strategies on the same
dataset when the real ground truth is not known
Be mindful that this function is an order of magnitude slower than other metrics such as the Adjusted Rand
Index
Read more in the User Guide
Parameters
labelstrue int array shape nsamples A clustering of the data into disjoint subsets
labelspred array shape nsamples A clustering of the data into disjoint subsets
averagemethod string optional default 'warn' How to compute the normalizer in the
denominator Possible options are 'min' 'geometric' 'arithmetic' and 'max' If 'warn'
'max' will be used The default will change to 'arithmetic' in version 022
New in version 020
Returns
ami float upperlimited by 10 The AMI returns a value of 1 when the two partitions are
identical ie perfectly matched Random partitions independent labellings have an ex
pected AMI around 0 on average hence can be negative
See also
adjustedrandscore Adjusted Rand Index
mutualinfoscore Mutual Information not adjusted for chance
References
12
Examples
Perfect labelings are both homogeneous and complete hence have score 10

from sklearnmetricscluster import adjustedmutualinfoscore
adjustedmutualinfoscore0 0 1 1 0 0 1 1

10
adjustedmutualinfoscore0 0 1 1 1 1 0 0

10
If classes members are completely split across different clusters the assignment is totally incomplete hence the AMI is null
adjustedmutualinfoscore0 0 0 0 0 1 2 3

00
Examples using sklearnmetricsadjustedmutualinfoscore
•Demo of affinity propagation clustering algorithm
•Demo of DBSCAN clustering algorithm
•Adjustment for chance in clustering performance evaluation
•A demo of KMeans clustering on the handwritten digits data
sklearnmetrics adjustedrandscore
sklearnmetrics adjustedrandscore labelstrue labelspred
Rand index adjusted for chance
The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings
The raw RI score is then “adjusted for chance” into the ARI score using the following scheme
ARI RI ExpectedRI maxRI ExpectedRI
The adjusted Rand index is thus ensured to have a value close to 00 for random labeling independently of the number of clusters and samples and exactly 10 when the clusterings are identical up to a permutation
ARI is a symmetric measure
adjustedrandscorea b adjustedrandscoreb a
Read more in the User Guide
Parameters
labelstrue int array shape nsamples Ground truth class labels to be used as a reference
labelspred array shape nsamples Cluster labels to evaluate
Returns
arifloat Similarity score between 10 and 10 Random labelings have an ARI close to 00
10 stands for perfect match

•Clustering text documents using kmeans
sklearnmetrics calinskiharabaszscore
sklearnmetrics calinskiharabaszscore Xlabels
Compute the Calinski and Harabasz score
It is also known as the Variance Ratio Criterion
The score is defined as ratio between the withincluster dispersion and the betweencluster dispersion
Read more in the User Guide

Parameters
Xarraylike shape nsamples nfeatures List ofnfeatures dimensional data
points Each row corresponds to a single data point
labels arraylike shape nsamples Predicted labels for each sample
Returns
score float The resulting CalinskiHarabasz score
References
1
sklearnmetrics daviesbouldinscore
sklearnmetrics daviesbouldinscore Xlabels
Computes the DaviesBouldin score
The score is defined as the average similarity measure of each cluster with its most similar cluster where
similarity is the ratio of withincluster distances to betweencluster distances Thus clusters which are farther
apart and less dispersed will result in a better score
The minimum score is zero with lower values indicating better clustering
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures List ofnfeatures dimensional data
points Each row corresponds to a single data point
labels arraylike shape nsamples Predicted labels for each sample
Returns
score float The resulting DaviesBouldin score
References
1
sklearnmetrics completenessscore
sklearnmetrics completenessscore labelstrue labelspred
Completeness metric of a cluster labeling given a ground truth
A clustering result satisfies completeness if all the data points that are members of a given class are elements of
the same cluster
This metric is independent of the absolute values of the labels a permutation of the class or cluster label values
won’t change the score value in any way
This metric is not symmetric switching labeltrue withlabelpred will return the
homogeneityscore which will be different in general
Read more in the User Guide

Parameters
labelstrue int array shape nsamples ground truth class labels to be used as a reference
labelspred array shape nsamples cluster labels to evaluate
Returns
completeness float score between 00 and 10 10 stands for perfectly complete labeling
See also
homogeneityscore
vmeasurescore

sklearnmetricscluster contingencymatrix
sklearnmetricscluster contingencymatrix labelstrue labelspred epsNone
sparseFalse
Build a contingency matrix describing the relationship between labels
Parameters
labelstrue int array shape nsamples Ground truth class labels to be used as a reference
labelspred array shape nsamples Cluster labels to evaluate
eps None or float optional If a float that value is added to all values in the contingency
matrix This helps to stop NaN propagation If None nothing is adjusted
sparse boolean optional If True return a sparse CSR continency matrix If eps is not
None andsparse is True will throw ValueError
New in version 018
Returns
contingency arraylike sparse shapenclassestrue nclassespred Matrix □such that
□□□is the number of samples in true class □and in predicted class □ Ifeps is None
the dtype of this array will be integer If eps is given the dtype will be float Will be a
scipysparsecsrmatrix ifsparseTrue
sklearnmetrics fowlkesmallowsscore
sklearnmetrics fowlkesmallowsscore labelstrue labelspred sparseFalse
Measure the similarity of two clusterings of a set of points
The FowlkesMallows index FMI is defined as the geometric mean between of the precision and recall
FMI TP sqrtTP FP TP FN
WhereTPis the number of True Positive ie the number of pair of points that belongs in the same clusters
in bothlabelstrue andlabelspred FPis the number of False Positive ie the number of pair of
points that belongs in the same clusters in labelstrue and not inlabelspred andFNis the number
ofFalse Negative ie the number of pair of points that belongs in the same clusters in labelspred and not
inlabelsTrue
The score ranges from 0 to 1 A high value indicates a good similarity between two clusters
Read more in the User Guide
Parameters
labelstrue int array shape nsamples A clustering of the data into disjoint subsets
labelspred array shape nsamples A clustering of the data into disjoint subsets
sparse bool Compute contingency matrix internally with sparse matrix
Returns
score float The resulting FowlkesMallows score
References

sklearnmetrics homogeneitycompletenessvmeasure
sklearnmetrics homogeneitycompletenessvmeasure labelstrue labelspred
beta10
Compute the homogeneity and completeness and VMeasure scores at once
Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples
A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class
A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster
Both scores have positive values between 00 and 10 larger values being desirable
Those 3 metrics are independent of the absolute values of the labels a permutation of the class or cluster label values won’t change the score values in any way
VMeasure is furthermore symmetric swapping labelstrue andlabelpred will give the same score This does not hold for homogeneity and completeness VMeasure is identical to normalizedmutualinfoscore with the arithmetic averaging method
Read more in the User Guide
Parameters
labelstrue int array shape nsamples ground truth class labels to be used as a reference
labelspred array shape nsamples cluster labels to evaluate
beta float Ratio of weight attributed to homogeneity vscompleteness Ifbeta is greater than 1 completeness is weighted more strongly in the calculation If beta is less than 1 homogeneity is weighted more strongly
Returns
homogeneity float score between 00 and 10 10 stands for perfectly homogeneous labeling
completeness float score between 00 and 10 10 stands for perfectly complete labeling
vmeasure float harmonic mean of the first two

sklearnmetrics mutualinfoscore
sklearnmetrics mutualinfoscore labelstrue labelspred contingencyNone
Mutual Information between two clusterings
The Mutual Information is a measure of the similarity between two labels of the same data Where □□is the number of the samples in cluster □□and□□is the number of the samples in cluster □□ the Mutual Information between clusterings □and□is given as
□□□ □ □∑
□1□∑
□1□□∩□□
□log□□□∩□□
□□□□
This metric is independent of the absolute values of the labels a permutation of the class or cluster label values won’t change the score value in any way
This metric is furthermore symmetric switching labeltrue withlabelpred will return the same score value This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known
Read more in the User Guide
Parameters
labelstrue int array shape nsamples A clustering of the data into disjoint subsets
labelspred array shape nsamples A clustering of the data into disjoint subsets
contingency None array sparse matrix shape nclassestrue nclassespred A con tingency matrix given by the contingencymatrix function If value is None it will be computed otherwise the given value is used with labelstrue andlabelspred ignored
Returns
mifloat Mutual information a nonnegative value
See also
adjustedmutualinfoscore Adjusted against chance Mutual Information
normalizedmutualinfoscore Normalized Mutual Information

Examples using sklearnmetricsmutualinfoscore
•Adjustment for chance in clustering performance evaluation
sklearnmetrics normalizedmutualinfoscore
sklearnmetrics normalizedmutualinfoscore labelstrue labelspred aver
agemethod'warn'
Normalized Mutual Information between two clusterings
Normalized Mutual Information NMI is a normalization of the Mutual Information MI score to scale the
results between 0 no mutual information and 1 perfect correlation In this function mutual information
is normalized by some generalized mean of Hlabelstrue andHlabelspred defined by the
averagemethod
This measure is not adjusted for chance Therefore adjustedmutualinfoscore might be preferred
This metric is independent of the absolute values of the labels a permutation of the class or cluster label values
won't change the score value in any way
This metric is furthermore symmetric switching labeltrue withlabelpred will return the same score
value This can be useful to measure the agreement of two independent label assignments strategies on the same
dataset when the real ground truth is not known
Read more in the User Guide
Parameters
labelstrue int array shape nsamples A clustering of the data into disjoint subsets
labelspred array shape nsamples A clustering of the data into disjoint subsets
averagemethod string optional default 'warn' How to compute the normalizer in the
denominator Possible options are 'min' 'geometric' 'arithmetic' and 'max' If 'warn'
'geometric' will be used The default will change to 'arithmetic' in version 022
New in version 020
Returns
nmi float score between 00 and 10 10 stands for perfectly complete labeling
See also
vmeasurescore VMeasure NMI with arithmetic mean option
adjustedrandscore Adjusted Rand Index
adjustedmutualinfoscore Adjusted Mutual Information adjusted against chance
Examples
Perfect labelings are both homogeneous and complete hence have score 10
```
from sklearnmetricscluster import normalizedmutualinfoscore

sklearnmetrics silhouettescore
sklearnmetrics silhouettescore Xlabels metric'euclidean' samplesizeNone ran
domstateNone kwds
Compute the mean Silhouette Coefficient of all samples
The Silhouette Coefficient is calculated using the mean intracluster distance a and the mean nearestcluster
distance b for each sample The Silhouette Coefficient for a sample is b a maxa b To clarify
bis the distance between a sample and the nearest cluster that the sample is not a part of Note that Silhouette
Coefficient is only defined if number of labels is 2 nlabels nsamples 1
This function returns the mean Silhouette Coefficient over all samples To obtain the values for each sample
usesilhouettesamples
The best value is 1 and the worst value is 1 Values near 0 indicate overlapping clusters Negative values
generally indicate that a sample has been assigned to the wrong cluster as a different cluster is more similar
Read more in the User Guide
Parameters
Xarray nsamplesa nsamplesa if metric "precomputed" or nsamplesa
nfeatures otherwise Array of pairwise distances between samples or a feature array
labels array shape nsamples Predicted labels for each sample
metric string or callable The metric to use when calculating distance between instances
in a feature array If metric is a string it must be one of the options allowed by
metricspairwisepairwisedistances If X is the distance array itself use
metricprecomputed
samplesize int or None The size of the sample to use when computing the Silhouette Co
efficient on a random subset of the data If samplesize is None no sampling is
used
randomstate int RandomState instance or None optional defaultNone The generator
used to randomly select a subset of samples If int randomstate is the seed used by the
random number generator If RandomState instance randomstate is the random number
generator If None the random number generator is the RandomState instance used by np
random Used when samplesize is not None
kwds optional keyword parameters Any further parameters are passed directly to the dis
tance function If using a scipyspatialdistance metric the parameters are still metric de
pendent See the scipy docs for usage examples
Returns
silhouette float Mean Silhouette Coefficient for all samples

sklearnmetricspairwise cosinesimilarity
sklearnmetricspairwise cosinesimilarity XYNone denseoutputTrue
Compute cosine similarity between samples in X and Y
Cosine similarity or the cosine kernel computes similarity as the normalized dot product of X and Y

KX Y X Y XY
On L2normalized data this function is equivalent to linearkernel
Read more in the User Guide
Parameters
Xndarray or sparse array shape nsamplesX nfeatures Input data
Yndarray or sparse array shape nsamplesY nfeatures Input data If None the output
will be the pairwise similarities between all samples in X
denseoutput boolean optional default True Whether to return dense output even when the
input is sparse If False the output is sparse if both input arrays are sparse
New in version 017 parameter denseoutput for dense output
Returns
kernel matrix array An array with shape nsamplesX nsamplesY
sklearnmetricspairwise cosinedistances
sklearnmetricspairwise cosinedistances XYNone
Compute cosine distance between samples in X and Y
Cosine distance is defined as 10 minus the cosine similarity
Read more in the User Guide
Parameters
Xarraylike sparse matrix with shape nsamplesX nfeatures
Yarraylike sparse matrix optional with shape nsamplesY nfeatures
Returns
distance matrix array An array with shape nsamplesX nsamplesY
See also
sklearnmetricspairwisecosinesimilarity
scipyspatialdistancecosine dense matrices only
sklearnmetricspairwise distancemetrics
sklearnmetricspairwise distancemetrics
Valid metrics for pairwisedistances
This function simply returns the valid pairwise distance metrics It exists to allow for a description of the
mapping for each of the valid strings
The valid distance metrics and the function they map to are

‘cityblock’ metricspairwisemanhattandistances
‘cosine’ metricspairwisecosinedistances
‘euclidean’ metricspairwiseeuclideandistances
‘haversine’ metricspairwisehaversinedistances
‘l1’ metricspairwisemanhattandistances
‘l2’ metricspairwiseeuclideandistances
‘manhattan’ metricspairwisemanhattandistances
Read more in the User Guide
sklearnmetricspairwise euclideandistances
sklearnmetricspairwise euclideandistances XYNone YnormsquaredNone
squaredFalse XnormsquaredNone
Considering the rows of X and YX as vectors compute the distance matrix between each pair of vectors
For efficiency reasons the euclidean distance between a pair of row vector x and y is computed as
distx y sqrtdotx x 2 dotx y doty y
This formulation has two advantages over other ways of computing distances First it is computationally ef
ficient when dealing with sparse data Second if one argument varies but the other remains unchanged then
dotx x andordoty y can be precomputed
However this is not the most precise way of doing this computation and the distance matrix returned by this
function may not be exactly symmetric as required by eg scipyspatialdistance functions
Read more in the User Guide
Parameters
Xarraylike sparse matrix shape nsamples1 nfeatures
Yarraylike sparse matrix shape nsamples2 nfeatures
Ynormsquared arraylike shape nsamples2 optional Precomputed dotproducts of
vectors in Y eg Y2sumaxis1 May be ignored in some cases see the note
below
squared boolean optional Return squared Euclidean distances
Xnormsquared arraylike shape nsamples1 optional Precomputed dotproducts of
vectors in X eg X2sumaxis1 May be ignored in some cases see the note
below
Returns
distances array shape nsamples1 nsamples2
See also
paireddistances distances betweens pairs of elements of X and Y
Notes
To achieve better accuracy Xnormsquared andYnormsquared may be unused if they are passed as
float32

Examples
```
 from sklearnmetricspairwise import euclideandistances
X  0 1 1 1
 distance between rows of X
euclideandistancesX X
array0 1

 get distance to origin
euclideandistancesX 0 0
array1
141421356
```
sklearnmetricspairwise haversinedistances
sklearnmetricspairwise haversinedistances XYNone
Compute the Haversine distance between samples in X and Y
The Haversine or great circle distance is the angular distance between two points on the surface of a sphere The first distance of each point is assumed to be the latitude the second is the longitude given in radians The dimension of the data must be 2
□□ □ 2 arcsin√
sin2□1−□12 cos □1 cos □1 sin2□2−□22
Parameters
Xarraylike shape nsamples1 2
Yarraylike shape nsamples2 2 optional
Returns
distance array shape nsamples1 nsamples2
Notes
As the Earth is nearly spherical the haversine formula provides a good approximation of the distance between two points of the Earth surface with a less than 1 error on average
Examples
We want to calculate the distance between the Ezeiza Airport Buenos Aires Argentina and the Charles de Gaulle Airport Paris France
```
 from sklearnmetricspairwise import haversinedistances
bsas  3483333 585166646
paris  490083899664 253844117956
result  haversinedistancesbsas paris
result63710001000  multiply by Earth radius to get kilometers
array 0  1127945379464
1127945379464 0
```

sklearnmetricspairwise kernelmetrics
sklearnmetricspairwise kernelmetrics
Valid metrics for pairwisekernels
This function simply returns the valid pairwise distance metrics It exists however to allow for a verbose description of the mapping for each of the valid strings
The valid distance metrics and the function they map to are

sklearnmetricspairwise laplaciankernel
sklearnmetricspairwise laplaciankernel XYNone gammaNone
Compute the laplacian kernel between X and Y
The laplacian kernel is defined as
Kx y expgamma xy1
for each pair of rows x in X and y in Y Read more in the User Guide
New in version 017
Parameters
Xarray of shape nsamplesX nfeatures
Yarray of shape nsamplesY nfeatures
gamma float default None If None defaults to 10 nfeatures
Returns
kernelmatrix array of shape nsamplesX nsamplesY
sklearnmetricspairwise linearkernel
sklearnmetricspairwise linearkernel XYNone denseoutputTrue
Compute the linear kernel between X and Y
Read more in the User Guide
Parameters
Xarray of shape nsamples1 nfeatures

Yarray of shape nsamples2 nfeatures
denseoutput boolean optional default True Whether to return dense output even when the
input is sparse If False the output is sparse if both input arrays are sparse
New in version 020
Returns
Gram matrix array of shape nsamples1 nsamples2
sklearnmetricspairwise manhattandistances
sklearnmetricspairwise manhattandistances XYNone sumoverfeaturesTrue
Compute the L1 distances between the vectors in X and Y
With sumoverfeatures equal to False it returns the componentwise distances
Read more in the User Guide
Parameters
Xarraylike An array with shape nsamplesX nfeatures
Yarraylike optional An array with shape nsamplesY nfeatures
sumoverfeatures bool defaultTrue If True the function returns the pairwise distance ma
trix else it returns the componentwise L1 pairwisedistances Not supported for sparse ma
trix inputs
Returns
Darray If sumoverfeatures is False shape is nsamplesX nsamplesY nfeatures and
D contains the componentwise L1 pairwisedistances ie absolute difference else shape is
nsamplesX nsamplesY and D contains the pairwise L1 distances
Examples
```
from sklearnmetricspairwise import manhattandistances
manhattandistances3 3
array0
manhattandistances3 2
array1
manhattandistances2 3

array1 1
1 1
```

sklearnmetricspairwise pairwisekernels
sklearnmetricspairwise pairwisekernels X YNone metric'linear' fil
terparamsFalse njobsNone kwds
Compute the kernel between arrays X and optional array Y
This method takes either a vector array or a kernel matrix and returns a kernel matrix If the input is a vector array the kernels are computed If the input is a kernel matrix it is returned instead
This method provides a safe way to take a kernel matrix as input while preserving compatibility with many other algorithms that take a vector array
If Y is given default is None then the returned matrix is the pairwise kernel between the arrays from both X and Y
Valid values for metric are
'additivechi2' 'chi2' 'linear' 'poly' 'polynomial' 'rbf' 'laplacian' 'sigmoid' 'cosine'
Read more in the User Guide
Parameters
Xarray nsamplesa nsamplesa if metric "precomputed" or nsamplesa
nfeatures otherwise Array of pairwise kernels between samples or a feature array
Yarray nsamplesb nfeatures A second feature array only if X has shape nsamplesa
nfeatures
metric string or callable The metric to use when calculating kernel between instances in a feature array If metric is a string it must be one of the metrics in pair
wisePAIRWISEKERNELFUNCTIONS If metric is "precomputed" X is assumed to be a kernel matrix Alternatively if metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays from X as input and return a value indicating the distance between them
filterparams boolean Whether to filter invalid parameters or not
njobs int or None optional defaultNone The number of jobs to use for the computation
This works by breaking down the pairwise matrix into njobs even slices and computing them in parallel
None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
kwds optional keyword parameters Any further parameters are passed directly to the kernel function
Returns
Karray nsamplesa nsamplesa or nsamplesa nsamplesb A kernel matrix K such that Ki j is the kernel between the ith and jth vectors of the given matrix X if Y is None
If Y is not None then Ki j is the kernel between the ith array from X and the jth array from Y
Notes
If metric is 'precomputed' Y is ignored and X is returned

scikitlearn user guide Release 0213
sklearnmetricspairwise polynomialkernel
sklearnmetricspairwise polynomialkernel XYNone degree3 gammaNone
coef01
Compute the polynomial kernel between X and Y
KX Y gamma X Y coef0degree
Read more in the User Guide
Parameters
Xndarray of shape nsamples1 nfeatures
Yndarray of shape nsamples2 nfeatures
degree int default 3
gamma float default None if None defaults to 10 nfeatures
coef0 float default 1
Returns
Gram matrix array of shape nsamples1 nsamples2
sklearnmetricspairwise rbfkernel
sklearnmetricspairwise rbfkernel XYNone gammaNone
Compute the rbf gaussian kernel between X and Y
Kx y expgamma xy2
for each pair of rows x in X and y in Y
Read more in the User Guide
Parameters
Xarray of shape nsamplesX nfeatures
Yarray of shape nsamplesY nfeatures
gamma float default None If None defaults to 10 nfeatures
Returns
kernelmatrix array of shape nsamplesX nsamplesY
sklearnmetricspairwise sigmoidkernel
sklearnmetricspairwise sigmoidkernel XYNone gammaNone coef01
Compute the sigmoid kernel between X and Y
KX Y tanhgamma X Y coef0
Read more in the User Guide
Parameters
Xndarray of shape nsamples1 nfeatures
Yndarray of shape nsamples2 nfeatures
624sklearnmetrics Metrics 2049

gamma float default None If None defaults to 10 nfeatures
coef0 float default 1
Returns
Gram matrix array of shape nsamples1 nsamples2
sklearnmetricspairwise pairedeuclideandistances
sklearnmetricspairwise pairedeuclideandistances XY
Computes the paired euclidean distances between X and Y
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures
Yarraylike shape nsamples nfeatures
Returns
distances ndarray nsamples
sklearnmetricspairwise pairedmanhattandistances
sklearnmetricspairwise pairedmanhattandistances XY
Compute the L1 distances between the vectors in X and Y
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures
Yarraylike shape nsamples nfeatures
Returns
distances ndarray nsamples
sklearnmetricspairwise pairedcosinedistances
sklearnmetricspairwise pairedcosinedistances XY
Computes the paired cosine distances between X and Y
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures
Yarraylike shape nsamples nfeatures
Returns
distances ndarray shape nsamples

Notes
The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm
sklearnmetricspairwise paireddistances
sklearnmetricspairwise paireddistances XYmetric’euclidean’ kwds
Computes the paired distances between X and Y
Computes the distances between X0 Y0 X1 Y1 etc
Read more in the User Guide
Parameters
Xndarray nsamples nfeatures Array 1 for distance computation
Yndarray nsamples nfeatures Array 2 for distance computation
metric string or callable The metric to use when calculating distance between instances in a feature array If metric is a string it must be one of the options specified in PAIREDDISTANCES including “euclidean” “manhattan” or “cosine” Alternatively if metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays from X as input and return a value indicating the distance between them
Returns
distances ndarray nsamples
See also
pairwisedistances Computes the distance between every pair of samples
Examples
```
 from sklearnmetricspairwise import paireddistances
X  0 1 1 1
Y  0 1 2 1
paireddistancesX Y
array0 1
```
sklearnmetrics pairwisedistances
sklearnmetrics pairwisedistances XYNone metric’euclidean’ njobsNone kwds
Compute the distance matrix from a vector array X and optional Y
This method takes either a vector array or a distance matrix and returns a distance matrix If the input is a vector array the distances are computed If the input is a distances matrix it is returned instead
This method provides a safe way to take a distance matrix as input while preserving compatibility with many other algorithms that take a vector array
If Y is given default is None then the returned matrix is the pairwise distance between the arrays from both X and Y

Valid values for metric are
• From scikitlearn ‘cityblock’ ‘cosine’ ‘euclidean’ ‘l1’ ‘l2’ ‘manhattan’ These metrics support sparse matrix inputs
• From scipyspatialdistance ‘braycurtis’ ‘canberra’ ‘chebyshev’ ‘correlation’ ‘dice’ ‘hamming’ ‘jaccard’ ‘kulsinski’ ‘mahalanobis’ ‘minkowski’ ‘rogerstanimoto’ ‘russellrao’ ‘seuclidean’ ‘sokalmichener’ ‘sokalsneath’ ‘sqeuclidean’ ‘yule’ See the documentation for scipyspatialdistance for details on these metrics These metrics do not support sparse matrix inputs
Note that in the case of ‘cityblock’ ‘cosine’ and ‘euclidean’ which are valid scipyspatialdistance metrics the scikitlearn implementation will be used which is faster and has support for sparse matrices except for ‘cityblock’ For a verbose description of the metrics from scikitlearn see the doc of the sklearnpairwisedistancemetrics function
Read more in the User Guide
Parameters
Xarray nsamplesa nsamplesa if metric “precomputed” or nsamplesa nfeatures otherwise Array of pairwise distances between samples or a feature array
Yarray nsamplesb nfeatures optional An optional second feature array Only allowed if metric “precomputed”
metric string or callable The metric to use when calculating distance between instances in a feature array If metric is a string it must be one of the options allowed by scipyspatialdistancepdist for its metric parameter or a metric listed in pairwisePAIRWISEDISTANCEFUNCTIONS If metric is “precomputed” X is assumed to be a distance matrix Alternatively if metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays from X as input and return a value indicating the distance between them
njobs int or None optional defaultNone The number of jobs to use for the computation This works by breaking down the pairwise matrix into njobs even slices and computing them in parallel
None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
kwds optional keyword parameters Any further parameters are passed directly to the distance function If using a scipyspatialdistance metric the parameters are still metric dependent See the scipy docs for usage examples
Returns
Darray nsamplesa nsamplesa or nsamplesa nsamplesb A distance matrix D such that Di j is the distance between the ith and jth vectors of the given matrix X if Y is None If Y is not None then Di j is the distance between the ith array from X and the jth array from Y
See also
pairwisedistanceschunked performs the same calculation as this function but returns a generator of chunks of the distance matrix in order to limit memory usage
paireddistances Computes the distances between corresponding elements of two arrays

Examples using sklearnmetricspairwisedistances
•Agglomerative clustering with different metrics
sklearnmetrics pairwisedistancesargmin
sklearnmetrics pairwisedistancesargmin X Y axis1 metric'euclidean'
batchsizeNone metrickwargsNone
Compute minimum distances between one point and a set of points
This function computes for each row in X the index of the row of Y which is closest according to the specified distance
This is mostly equivalent to calling
pairwisedistancesX YY metricmetricargminaxisaxis
but uses much less memory and is faster for large arrays
This function works with dense 2D arrays only
Parameters
Xarraylike Arrays containing points Respective shapes nsamples1 nfeatures and nsamples2 nfeatures
Yarraylike Arrays containing points Respective shapes nsamples1 nfeatures and nsamples2 nfeatures
axis int optional default 1 Axis along which the argmin and distances are to be computed
metric string or callable metric to use for distance computation Any metric from scikitlearn or scipyspatialdistance can be used
If metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays as input and return one value indicating the distance between them This works for Scipy's metrics but is less efficient than passing the metric name as a string
Distance matrices are not supported
Valid values for metric are
• from scikitlearn 'cityblock' 'cosine' 'euclidean' 'l1' 'l2' 'manhattan'
• from scipyspatialdistance 'braycurtis' 'canberra' 'chebyshev' 'correlation' 'dice' 'hamming' 'jaccard' 'kulsinski' 'mahalanobis' 'minkowski' 'rogerstanimoto' 'rus sellrao' 'seuclidean' 'sokalmichener' 'sokalsneath' 'sqeuclidean' 'yule'
See the documentation for scipyspatialdistance for details on these metrics
batchsize integer Deprecated since version 020 Deprecated for removal in 022 Use sklearnsetconfigworkingmemory instead
metrickwargs dict keyword arguments to pass to specified metric function
Returns
argmin numpyndarray Yargmini is the row in Y that is closest to Xi
See also
sklearnmetricspairwisedistances

sklearnmetricspairwisedistancesargminmin
Examples using sklearnmetricspairwisedistancesargmin
•Color Quantization using KMeans
•Comparison of the KMeans and MiniBatchKMeans clustering algorithms
sklearnmetrics pairwisedistancesargminmin
sklearnmetrics pairwisedistancesargminmin XYaxis1 metric’euclidean’
batchsizeNone metrickwargsNone
Compute minimum distances between one point and a set of points
This function computes for each row in X the index of the row of Y which is closest according to the specified
distance The minimal distances are also returned
This is mostly equivalent to calling
pairwisedistancesX YY metricmetricargminaxisaxis pairwisedistancesX YY
metricmetricminaxisaxis
but uses much less memory and is faster for large arrays
Parameters
Xarraylike sparse matrix shape nsamples1 nfeatures Array containing points
Yarraylike sparse matrix shape nsamples2 nfeatures Arrays containing points
axis int optional default 1 Axis along which the argmin and distances are to be computed
metric string or callable default ‘euclidean’ metric to use for distance computation Any
metric from scikitlearn or scipyspatialdistance can be used
If metric is a callable function it is called on each pair of instances rows and the resulting
value recorded The callable should take two arrays as input and return one value indicating
the distance between them This works for Scipy’s metrics but is less efficient than passing
the metric name as a string
Distance matrices are not supported
Valid values for metric are
• from scikitlearn ‘cityblock’ ‘cosine’ ‘euclidean’ ‘l1’ ‘l2’ ‘manhattan’
• from scipyspatialdistance ‘braycurtis’ ‘canberra’ ‘chebyshev’ ‘correlation’ ‘dice’
‘hamming’ ‘jaccard’ ‘kulsinski’ ‘mahalanobis’ ‘minkowski’ ‘rogerstanimoto’ ‘rus
sellrao’ ‘seuclidean’ ‘sokalmichener’ ‘sokalsneath’ ‘sqeuclidean’ ‘yule’
See the documentation for scipyspatialdistance for details on these metrics
batchsize integer Deprecated since version 020 Deprecated for removal in 022 Use
sklearnsetconfigworkingmemory instead
metrickwargs dict optional Keyword arguments to pass to specified metric function
Returns
argmin numpyndarray Yargmini is the row in Y that is closest to Xi
distances numpyndarray distancesi is the distance between the ith row in X and the
argminith row in Y

sklearnmetricspairwisedistancesargmin
sklearnmetrics pairwisedistanceschunked
sklearnmetrics pairwisedistanceschunked XYNone reducefuncNone met
ric'euclidean' njobsNone work
ingmemoryNone kwds
Generate a distance matrix chunk by chunk with optional reduction
In cases where not all of a pairwise distance matrix needs to be stored at once this is used to calculate pairwise
distances in workingmemory sized chunks If reducefunc is given it is run on each chunk and its
return values are concatenated into lists arrays or sparse matrices
Parameters
Xarray nsamplesa nsamplesa if metric "precomputed" or nsamplesa
nfeatures otherwise Array of pairwise distances between samples or a feature array
Yarray nsamplesb nfeatures optional An optional second feature array Only allowed
if metric "precomputed"
reducefunc callable optional The function which is applied on each chunk of the distance
matrix reducing it to needed values reducefuncDchunk start is called re
peatedly where Dchunk is a contiguous vertical slice of the pairwise distance matrix
starting at row start It should return an array a list or a sparse matrix of length
Dchunkshape0 or a tuple of such objects
If None pairwisedistanceschunked returns a generator of vertical chunks of the distance
matrix
metric string or callable The metric to use when calculating distance between in
stances in a feature array If metric is a string it must be one of the options al
lowed by scipyspatialdistancepdist for its metric parameter or a metric listed in pair
wisePAIRWISEDISTANCEFUNCTIONS If metric is "precomputed" X is assumed to
be a distance matrix Alternatively if metric is a callable function it is called on each pair
of instances rows and the resulting value recorded The callable should take two arrays
from X as input and return a value indicating the distance between them
njobs int or None optional defaultNone The number of jobs to use for the computation
This works by breaking down the pairwise matrix into njobs even slices and computing
them in parallel
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
workingmemory int optional The sought maximum memory for temporary
distance matrix chunks When None default the value of sklearn
getconfigworkingmemory is used
'kwds' optional keyword parameters Any further parameters are passed directly to the dis
tance function If using a scipyspatialdistance metric the parameters are still metric de
pendent See the scipy docs for usage examples
Yields

Dchunk array or sparse matrix A contiguous slice of distance matrix optionally processed
byreducefunc

Variational Bayesian estimation of a Gaussian mixture
This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution The effective number of components can be inferred from the data
This class implements two types of prior for the weights distribution a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components called the Stickbreaking representation The number of components actually used almost always depends on the data
New in version 018
Read more in the User Guide
Parameters
ncomponents int defaults to 1 The number of mixture components Depending on the data and the value of the weightconcentrationprior the model can decide to not use all the components by setting some component weights to values very close to zero The number of effective components is therefore smaller than ncomponents
covariancetype 'full' 'tied' 'diag' 'spherical' defaults to 'full' String describing the type of covariance parameters to use Must be one of
full each component has its own general covariance matrix
tied all components share the same general covariance matrix
diag each component has its own diagonal covariance matrix
spherical each component has its own single variance
tolfloat defaults to 1e3 The convergence threshold EM iterations will stop when the lower bound average gain on the likelihood of the training data with respect to the model is below this threshold
regcovar float defaults to 1e6 Nonnegative regularization added to the diagonal of co variance Allows to assure that the covariance matrices are all positive
maxiter int defaults to 100 The number of EM iterations to perform

ninit int defaults to 1 The number of initializations to perform The result with the highest lower bound value on the likelihood is kept
initparams ‘kmeans’ ‘random’ defaults to ‘kmeans’ The method used to initialize the weights the means and the covariances Must be one of
kmeans responsibilities are initialized using kmeans
random responsibilities are initialized randomly
weightconcentrationpriortype str defaults to ‘dirichletprocess’ String describing the type of the weight concentration prior Must be one of
dirichletprocess using the Stickbreaking representation
dirichletdistribution can favor more uniform weights
weightconcentrationprior float None optional The dirichlet concentration of each com ponent on the weight distribution Dirichlet This is commonly called gamma in the litera ture The higher concentration puts more mass in the center and will lead to more compo nents being active while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex The value of the parameter must be greater than 0 If it is None it’s set to 1 ncomponents
meanprecisionprior float None optional The precision prior on the mean distribution Gaussian Controls the extend to where means can be placed Larger values concentrate the means of each clusters around meanprior The value of the parameter must be greater than 0 If it is None it’s set to 1
meanprior arraylike shape nfeatures optional The prior on the mean distribution Gaussian If it is None it’s set to the mean of X
degreesoffreedomprior float None optional The prior of the number of degrees of freedom on the covariance distributions Wishart If it is None it’s set to nfeatures
covarianceprior float or arraylike optional The prior on the covariance distribution Wishart If it is None the emiprical covariance prior is initialized using the covariance of X The shape depends on covariancetype
nfeatures nfeatures iffull
nfeatures nfeatures iftied
nfeatures ifdiag
float ifspherical
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
warmstart bool default to False If ‘warmstart’ is True the solution of the last fitting is used as initialization for the next call of fit This can speed up convergence when fit is called several times on similar problems See the Glossary
verbose int default to 0 Enable verbose output If 1 then it prints the current initialization and each iteration step If greater than 1 then it prints also the log probability and the time needed for each step
verboseinterval int default to 10 Number of iteration done before the next print
Attributes
weights arraylike shape ncomponents The weights of each mixture components

means arraylike shape ncomponents nfeatures The mean of each mixture component
covariances arraylike The covariance of each mixture component The shape depends on covariancetype
ncomponents ifspherical
nfeatures nfeatures iftied
ncomponents nfeatures ifdiag
ncomponents nfeatures nfeatures iffull
precisions arraylike The precision matrices for each component in the mixture A precision matrix is the inverse of a covariance matrix A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the loglikelihood of new samples at test time The shape depends on covariancetype
ncomponents ifspherical
nfeatures nfeatures iftied
ncomponents nfeatures ifdiag

fitselfXyNone
Estimate model parameters with the EM algorithm

The method fits the model ninit times and sets the parameters with which the model has the largest likelihood or lower bound Within each trial the method iterates between Estep and Mstep formaxiter times until the change of likelihood or lower bound is less than tol otherwise a ConvergenceWarning is raised If warmstart isTrue thenninit is ignored and a single initialization is performed upon the first call Upon consecutive calls training starts where it left off

Parameters

Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points Each row corresponds to a single data point

Returns

self

fitpredict selfXyNone

Estimate model parameters using X and predict the labels for X

The method fits the model ninit times and sets the parameters with which the model has the largest likelihood or lower bound Within each trial the method iterates between Estep and Mstep for maxiter times until the change of likelihood or lower bound is less than tol otherwise a ConvergenceWarning is raised After fitting it predicts the most probable label for the input data points

New in version 020

Parameters

Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points Each row corresponds to a single data point

Returns

labels array shape nsamples Component labels

getparams selfdeepTrue

Get parameters for this estimator

Parameters

deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators

Returns

params mapping of string to any Parameter names mapped to their values

predictselfX

Predict the labels for the data samples in X using trained model

Parameters

Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points Each row corresponds to a single data point

Returns

labels array shape nsamples Component labels

predictproba selfX

Predict posterior probability of each component given the data

Parameters

Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points Each row corresponds to a single data point

Returns
resp array shape nsamples ncomponents Returns the probability each Gaussian
state in the model given each sample
sampleselfnsamples1
Generate random samples from the fitted Gaussian distribution
Parameters
nsamples int optional Number of samples to generate Defaults to 1
Returns
Xarray shape nsamples nfeatures Randomly generated sample
yarray shape nsamples Component labels
scoreselfXyNone
Compute the persample average loglikelihood of the given data X
Parameters
Xarraylike shape nsamples ndimensions List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
loglikelihood float Log likelihood of the Gaussian mixture given X
scoresamples selfX
Compute the weighted log probabilities for each sample
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
logprob array shape nsamples Log probabilities of each data point in X
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Xarray of shape nsamples ndimensions
Returns
aicfloat The lower the better
bicselfX
Bayesian information criterion for the current model on the input X
Parameters
Xarray of shape nsamples ndimensions
Returns
bicfloat The lower the better
fitselfXyNone
Estimate model parameters with the EM algorithm
The method fits the model ninit times and sets the parameters with which the model has the
largest likelihood or lower bound Within each trial the method iterates between Estep and Mstep

formaxiter times until the change of likelihood or lower bound is less than tol otherwise a
ConvergenceWarning is raised If warmstart isTrue thenninit is ignored and a single
initialization is performed upon the first call Upon consecutive calls training starts where it left off
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
self
fitpredict selfXyNone
Estimate model parameters using X and predict the labels for X
The method fits the model ninit times and sets the parameters with which the model has the largest likeli
hood or lower bound Within each trial the method iterates between Estep and Mstep for maxiter times
until the change of likelihood or lower bound is less than tol otherwise a ConvergenceWarning is
raised After fitting it predicts the most probable label for the input data points
New in version 020
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
labels array shape nsamples Component labels
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict the labels for the data samples in X using trained model
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
labels array shape nsamples Component labels
predictproba selfX
Predict posterior probability of each component given the data
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns

resp array shape nsamples ncomponents Returns the probability each Gaussian
state in the model given each sample
sampleselfnsamples1
Generate random samples from the fitted Gaussian distribution
Parameters
nsamples int optional Number of samples to generate Defaults to 1
Returns
Xarray shape nsamples nfeatures Randomly generated sample
yarray shape nsamples Component labels
scoreselfXyNone
Compute the persample average loglikelihood of the given data X
Parameters
Xarraylike shape nsamples ndimensions List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
loglikelihood float Log likelihood of the Gaussian mixture given X
scoresamples selfX
Compute the weighted log probabilities for each sample
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
logprob array shape nsamples Log probabilities of each data point in X
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnmixtureGaussianMixture
•Comparing different clustering algorithms on toy datasets
•Density Estimation for a Gaussian mixture
•Gaussian Mixture Model Ellipsoids
•Gaussian Mixture Model Selection
•GMM covariances
•Gaussian Mixture Model Sine Curve

sklearnmodelselection GroupKFold
classsklearnmodelselection GroupKFold nsplits’warn’
Kfold iterator variant with nonoverlapping groups
The same group will not appear in two different folds the number of distinct groups has to be at least equal to
the number of folds
The folds are approximately balanced in the sense that the number of distinct groups is approximately the same
in each fold
Parameters
nsplits int default3 Number of folds Must be at least 2
Changed in version 020 nsplits default value will change from 3 to 5 in v022
See also
LeaveOneGroupOut For splitting the data according to explicit domainspecific stratification of the dataset
Examples
```
import numpy as np
from sklearnmodelselection import GroupKFold
X  nparray1 2 3 4 5 6 7 8
y  nparray1 2 3 4
groups  nparray0 0 2 2

Methods
getnsplits self X y groups Returns the number of splitting iterations in the cross
validator
split self X y groups Generate indices to split data into training and test set
init selfnsplits'warn'
getnsplits selfXNone yNone groupsNone
Returns the number of splitting iterations in the crossvalidator
Parameters
Xobject Always ignored exists for compatibility
yobject Always ignored exists for compatibility
groups object Always ignored exists for compatibility
Returns
nsplits int Returns the number of splitting iterations in the crossvalidator
splitselfXyNone groupsNone
Generate indices to split data into training and test set
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike shape nsamples optional The target variable for supervised learning prob
lems
groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set
Yields
626sklearnmodelselection Model Selection 2069

train ndarray The training set indices for that split
test ndarray The testing set indices for that split
Examples using sklearnmodelselectionGroupKFold
•Visualizing crossvalidation behavior in scikitlearn
sklearnmodelselection GroupShuffleSplit
classsklearnmodelselection GroupShuffleSplit nsplits5 testsizeNone
trainsizeNone randomstateNone
ShuffleGroupsOut crossvalidation iterator
Provides randomized traintest indices to split data according to a thirdparty provided group This group infor
mation can be used to encode arbitrary domain specific stratifications of the samples as integers
For instance the groups could be the year of collection of the samples and thus allow for crossvalidation against
timebased splits
The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all
subsets of size punique groups whereas GroupShuffleSplit generates a userdetermined number of random test
splits each with a userdetermined fraction of unique groups
For example a less computationally intensive alternative to LeavePGroupsOutp10 would be
GroupShuffleSplittestsize10 nsplits100
Note The parameters testsize andtrainsize refer to groups and not to samples as in ShuffleSplit
Parameters
nsplits int default 5 Number of reshuffling splitting iterations
testsize float int None optional defaultNone If float should be between 00 and 10
and represent the proportion of the dataset to include in the test split If int represents the
absolute number of test groups If None the value is set to the complement of the train size
Iftrainsize is also None it will be set to 02
trainsize float int or None default is None If float should be between 00 and 10 and
represent the proportion of the groups to include in the train split If int represents the
absolute number of train groups If None the value is automatically set to the complement
of the test size
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
Methods
getnsplits self X y groups Returns the number of splitting iterations in the cross
validator
split self X y groups Generate indices to split data into training and test set
init selfnsplits5 testsizeNone trainsizeNone randomstateNone

getnsplits selfXNone yNone groupsNone
Returns the number of splitting iterations in the crossvalidator
Parameters
Xobject Always ignored exists for compatibility
yobject Always ignored exists for compatibility
groups object Always ignored exists for compatibility
Returns
nsplits int Returns the number of splitting iterations in the crossvalidator
splitselfXyNone groupsNone
Generate indices to split data into training and test set
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike shape nsamples optional The target variable for supervised learning prob
lems
groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set
Yields
train ndarray The training set indices for that split
test ndarray The testing set indices for that split
Notes
Randomized CV splitters may return different results for each call of split You can make the results
identical by setting randomstate to an integer
Examples using sklearnmodelselectionGroupShuffleSplit
•Visualizing crossvalidation behavior in scikitlearn
sklearnmodelselection KFold
classsklearnmodelselection KFoldnsplits‘warn’ shuffleFalse randomstateNone
KFolds crossvalidator
Provides traintest indices to split data in traintest sets Split dataset into k consecutive folds without shuffling
by default
Each fold is then used once as a validation while the k 1 remaining folds form the training set
Read more in the User Guide
Parameters
nsplits int default3 Number of folds Must be at least 2
Changed in version 020 nsplits default value will change from 3 to 5 in v022

shuffle boolean optional Whether to shuffle the data before splitting into batches
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when shuffle True
See also
StratifiedKFold Takes group information into account to avoid building folds with imbalanced class
distributions for binary or multiclass classification tasks
GroupKFold Kfold iterator variant with nonoverlapping groups
RepeatedKFold Repeats KFold n times
Notes
The firstnsamples nsplits folds have size nsamples nsplits 1 other folds have
sizensamples nsplits wherensamples is the number of samples
Randomized CV splitters may return different results for each call of split You can make the results identical
by settingrandomstate to an integer
Examples
```

groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set This ‘groups’ parameter must always be specified to
calculate the number of splits though the other parameters can be omitted
Returns
nsplits int Returns the number of splitting iterations in the crossvalidator
splitselfXyNone groupsNone
Generate indices to split data into training and test set
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike of length nsamples optional The target variable for supervised learning
problems

groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set
Yields
train ndarray The training set indices for that split
test ndarray The testing set indices for that split
sklearnmodelselection LeavePGroupsOut
classsklearnmodelselection LeavePGroupsOut ngroups
Leave P Groups Out crossvalidator
Provides traintest indices to split data according to a thirdparty provided group This group information can be
used to encode arbitrary domain specific stratifications of the samples as integers
For instance the groups could be the year of collection of the samples and thus allow for crossvalidation against
timebased splits
The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with
all the samples assigned to pdifferent values of the groups while the latter uses samples all assigned the same
groups
Read more in the User Guide
Parameters
ngroups int Number of groups p to leave out in the test split
See also
GroupKFold Kfold iterator variant with nonoverlapping groups
Examples
```
 import numpy as np
 from sklearnmodelselection import LeavePGroupsOut

Methods
getnsplits self X y groups Returns the number of splitting iterations in the cross
validator
split self X y groups Generate indices to split data into training and test set
init selfngroups
getnsplits selfXNone yNone groupsNone
Returns the number of splitting iterations in the crossvalidator
Parameters
Xobject Always ignored exists for compatibility
yobject Always ignored exists for compatibility
groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set This ‘groups’ parameter must always be specified to
calculate the number of splits though the other parameters can be omitted
Returns
nsplits int Returns the number of splitting iterations in the crossvalidator
splitselfXyNone groupsNone
Generate indices to split data into training and test set
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike of length nsamples optional The target variable for supervised learning
problems
groups arraylike with shape nsamples Group labels for the samples used while split
ting the dataset into traintest set
Yields
train ndarray The training set indices for that split
test ndarray The testing set indices for that split
sklearnmodelselection LeaveOneOut
classsklearnmodelselection LeaveOneOut
LeaveOneOut crossvalidator
Provides traintest indices to split data in traintest sets Each sample is used once as a test set singleton while
the remaining samples form the training set
NoteLeaveOneOut is equivalent to KFoldnsplitsn andLeavePOutp1 wherenis the
number of samples

Due to the high number of test sets which is the same as the number of samples this crossvalidation method
can be very costly For large datasets one should favor KFold ShuffleSplit orStratifiedKFold
Read more in the User Guide
See also
LeaveOneGroupOut For splitting the data according to explicit domainspecific stratification of the dataset

Xarraylike shape nsamples nfeatures Training data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike of length nsamples The target variable for supervised learning problems
groups arraylike with shape nsamples optional Group labels for the samples used
while splitting the dataset into traintest set
Yields
train ndarray The training set indices for that split
test ndarray The testing set indices for that split
sklearnmodelselection LeavePOut
classsklearnmodelselection LeavePOut p
LeavePOut crossvalidator
Provides traintest indices to split data in traintest sets This results in testing on all distinct samples of size p
while the remaining n p samples form the training set in each iteration
NoteLeavePOutp is NOT equivalent to KFoldnsplitsnsamples p which creates non
overlapping test sets
Due to the high number of iterations which grows combinatorically with the number of samples this cross
validation method can be very costly For large datasets one should favor KFold StratifiedKFold or
ShuffleSplit
Read more in the User Guide
Parameters
pint Size of the test sets Must be strictly greater than the number of samples
Examples
```
 import numpy as np
 from sklearnmodelselection import LeavePOut
X  nparray1 2 3 4 5 6 7 8

Methods
getnsplits self X y groups Returns the number of splitting iterations in the cross validator
split self X y groups Generate indices to split data into training and test set
init selfnsplits10 testsizeNone trainsizeNone randomstateNone
getnsplits selfXNone yNone groupsNone
Returns the number of splitting iterations in the crossvalidator
Parameters
Xobject Always ignored exists for compatibility
yobject Always ignored exists for compatibility
groups object Always ignored exists for compatibility
Returns
nsplits int Returns the number of splitting iterations in the crossvalidator
splitselfXyNone groupsNone
Generate indices to split data into training and test set
Parameters
Xarraylike shape nsamples nfeatures Training data where nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples The target variable for supervised learning problems
groups arraylike with shape nsamples optional Group labels for the samples used while splitting the dataset into traintest set
Yields
train ndarray The training set indices for that split
test ndarray The testing set indices for that split
626sklearnmodelselection Model Selection 2085

Notes
Randomized CV splitters may return different results for each call of split You can make the results identical by setting randomstate to an integer
Examples using sklearnmodelselectionShuffleSplit
•Visualizing crossvalidation behavior in scikitlearn
•Plotting Learning Curves
•Scaling the regularization parameter for SVCs
sklearnmodelselection StratifiedKFold
classsklearnmodelselection StratifiedKFold nsplits'warn' shuffleFalse ran domstateNone
Stratified KFolds crossvalidator
Provides traintest indices to split data in traintest sets
This crossvalidation object is a variation of KFold that returns stratified folds The folds are made by preserving the percentage of samples for each class
Read more in the User Guide
Parameters
nsplits int default3 Number of folds Must be at least 2
Changed in version 020 nsplits default value will change from 3 to 5 in v022
shuffle boolean optional Whether to shuffle each class's samples before splitting into batches
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when shuffle True

6262 Splitter Functions
modelselectioncheckcv cv y classifier Input checker utility for building a crossvalidator
modelselectiontraintestsplit arrays
Split arrays or matrices into random train and test subsets
sklearnmodelselection checkcv
sklearnmodelselection checkcv cv‘warn’ yNone classifierFalse
Input checker utility for building a crossvalidator
Parameters

cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if classifier is True and yis either binary or multiclass
StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value will change from 3fold to 5fold in v022
yarraylike optional The target variable for supervised learning problems
classifier boolean optional default False Whether the task is a classification task in which
case stratified KFold will be used
Returns
checkedcv a crossvalidator instance The return value is a crossvalidator which generates
the traintest splits via the split method
sklearnmodelselection traintestsplit
sklearnmodelselection traintestsplit arrays options
Split arrays or matrices into random train and test subsets
Quick utility that wraps input validation and nextShuffleSplitsplitX y and application to
input data into a single call for splitting and optionally subsampling data in a oneliner
Read more in the User Guide
Parameters
arrays sequence of indexables with same length shape0 Allowed inputs are lists numpy
arrays scipysparse matrices or pandas dataframes
testsize float int or None optional defaultNone If float should be between 00 and 10
and represent the proportion of the dataset to include in the test split If int represents the
absolute number of test samples If None the value is set to the complement of the train
size Iftrainsize is also None it will be set to 025
trainsize float int or None defaultNone If float should be between 00 and 10 and
represent the proportion of the dataset to include in the train split If int represents the
absolute number of train samples If None the value is automatically set to the complement
of the test size
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
shuffle boolean optional defaultTrue Whether or not to shuffle the data before splitting If
shuffleFalse then stratify must be None
stratify arraylike or None defaultNone If not None data is split in a stratified fashion
using this as the class labels

Returns
splitting list length2 lenarrays List containing traintest split of inputs
New in version 016 If the input is sparse the output will be a scipysparse
csrmatrix Else output type is the same as the input type
Examples
```
 import numpy as np

njobsNone iid'warn' refitTrue
cv'warn' verbose0 predispatch'2njobs'
errorscore'raisedeprecating' re
turntrainscoreFalse
Exhaustive search over specified parameter values for an estimator
Important members are fit predict

GridSearchCV implements a “fit” and a “score” method It also implements “predict” “predictproba” “deci
sionfunction” “transform” and “inversetransform” if they are implemented in the estimator used
The parameters of the estimator used to apply these methods are optimized by crossvalidated gridsearch over
a parameter grid
Read more in the User Guide
Parameters
estimator estimator object This is assumed to implement the scikitlearn estimator interface
Either estimator needs to provide a score function or scoring must be passed
paramgrid dict or list of dictionaries Dictionary with parameters names string as keys and
lists of parameter settings to try as values or a list of such dictionaries in which case the
grids spanned by each dictionary in the list are explored This enables searching over any
sequence of parameter settings
scoring string callable listtuple dict or None default None A single string see The scoring
parameter defining model evaluation rules or a callable see Defining your scoring strategy
from metric functions to evaluate the predictions on the test set
For evaluating multiple metrics either give a list of unique strings or a dict with names as
keys and callables as values
NOTE that when using custom scorers each scorer should return a single value Metric
functions returning a listarray of values can be wrapped into multiple scorers that return
one value each
SeeSpecifying multiple metrics for evaluation for an example
If None the estimator’s score method is used
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
predispatch int or string optional Controls the number of jobs that get dispatched during
parallel execution Reducing this number can be useful to avoid an explosion of memory
consumption when more jobs get dispatched than CPUs can process This parameter can
be
• None in which case all the jobs are immediately created and spawned Use this for
lightweight and fastrunning jobs to avoid delays due to ondemand spawning of the jobs
• An int giving the exact number of total jobs that are spawned
• A string giving an expression as a function of njobs as in ‘2njobs’
iidboolean default‘warn’ If True return the average score across folds weighted by the
number of samples in each test set In this case the data is assumed to be identically dis
tributed across the folds and the loss minimized is the total loss per sample and not the
mean loss across the folds If False return the average score across folds Default is True
but will change to False in version 022 to correspond to the standard definition of cross
validation
Changed in version 020 Parameter iid will change from True to False by default in
version 022 and will be removed in 024
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold cross validation

• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if the estimator is a classifier and yis either binary or multiclass StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
refit boolean string or callable defaultTrue Refit an estimator using the best found param eters on the whole dataset
For multiple metric evaluation this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end
Where there are considerations other than maximum score in choosing a best estima torrefit can be set to a function which returns the selected bestindex given cvresults
The refitted estimator is made available at the bestestimator attribute and permits usingpredict directly on this GridSearchCV instance
Also for multiple metric evaluation the attributes bestindex bestscore and bestparams will only be available if refit is set and all of them will be determined wrt this specific scorer bestscore is not returned if refit is callable
Seescoring parameter to know more about multiple metric evaluation
Changed in version 020 Support for callable added
verbose integer Controls the verbosity the higher the more messages
errorscore ‘raise’ or numeric Value to assign to the score if an error occurs in estimator fitting If set to ‘raise’ the error is raised If a numeric value is given FitFailedWarning is raised This parameter does not affect the refit step which will always raise the error Default is ‘raise’ but from version 022 it will change to npnan
returntrainscore boolean defaultFalse If False thecvresults attribute will not include training scores Computing training scores is used to get insights on how differ ent parameter settings impact the overfittingunderfitting tradeoff However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance
Attributes
cvresults dict of numpy masked ndarrays A dict with keys as column headers and values as columns that can be imported into a pandas DataFrame
For instance the below given table

paramkernel	paramgamma	paramdegree	split0testscore	rankt
‘poly’	–	2	080	2
‘poly’	–	3	070	4
‘rbf’	01	–	080	3
‘rbf’	02	–	093	1

will be represented by a cvresults dict of

paramkernel maskedarraydata poly poly rbf rbf
mask   False False False False
paramgamma maskedarraydata   01 02
mask   True True False False
paramdegree maskedarraydata 20 30
mask   False False True True
split0testscore 080 070 080 093
split1testscore 082 050 070 078
meantestscore 081 060 075 085
stdtestscore 001 010 005 008
ranktestscore 2 4 3 1
split0trainscore 080 092 070 093
split1trainscore 082 055 070 087
meantrainscore 081 074 070 090
stdtrainscore 001 019 000 003
meanfittime 073 063 043 049
stdfittime 001 002 001 001
meanscoretime 001 006 004 004
stdscoretime 000 000 000 001
params kernel poly degree 2

NOTE
The keyparams is used to store a list of parameter settings dicts for all the parameter candidates
Themeanfittime stdfittime meanscoretime and stdscoretime are all in seconds
For multimetric evaluation the scores for all the scorers are available in the cvresults dict at the keys ending with that scorer's name scorername instead ofscore shown above 'split0testprecision' 'meantrainprecision' etc
bestestimator estimator or dict Estimator that was chosen by the search ie estimator which gave highest score or smallest loss if specified on the left out data Not available if refitFalse
Seerefit parameter for more information on allowed values
bestscore float Mean crossvalidated score of the bestestimator
For multimetric evaluation this is present only if refit is specified
bestparams dict Parameter setting that gave the best results on the hold out data
For multimetric evaluation this is present only if refit is specified
bestindex int The index of the cvresults arrays which corresponds to the best candidate parameter setting
The dict at searchcvresultsparamssearchbestindex gives the parameter setting for the best model that gives the highest mean score search bestscore
For multimetric evaluation this is present only if refit is specified
scorer function or a dict Scorer function used on the held out data to choose the best parameters for the model
626sklearnmodelselection Model Selection 2097

For multimetric evaluation this attribute holds the validated scoring dict which maps
the scorer key to the scorer callable
nsplits int The number of crossvalidation splits foldsiterations
refittime float Seconds used for refitting the best model on the whole dataset
This is present only if refit is not False
See also
ParameterGrid generates all the combinations of a hyperparameter grid
sklearnmodelselectiontraintestsplit utility function to split the data into a development
set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation
sklearnmetricsmakescorer Make a scorer from a performance metric or loss function
Notes
The parameters selected are those that maximize the score of the left out data unless an explicit score is passed
in which case it is used instead
Ifnjobs was set to a value higher than one the data is copied for each point in the grid and not njobs times
This is done for efficiency reasons if individual jobs take very little time but may raise errors if the dataset
is large and not enough memory is available A workaround in this case is to set predispatch Then
the memory is copied only predispatch many times A reasonable value for predispatch is2
njobs

Methods
decisionfunction self X Call decisionfunction on the estimator with the best found parameters
fitself X y groups Run fit with all sets of parameters
getparams self deep Get parameters for this estimator
inversetransform self Xt Call inversetransform on the estimator with the best found params
predict self X Call predict on the estimator with the best found param eters
predictlogproba self X Call predictlogproba on the estimator with the best found parameters
predictproba self X Call predictproba on the estimator with the best found parameters
score self X y Returns the score on the given data if the estimator has been refit
setparams self params Set the parameters of this estimator
transform self X Call transform on the estimator with the best found pa rameters
init selfestimator paramgrid scoringNone njobsNone iid'warn' refitTrue cv'warn' verbose0 predispatch'2njobs' errorscore'raisedeprecating' re turntrainscoreFalse
decisionfunction selfX
Call decisionfunction on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports decisionfunction
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti mator
fitselfXyNone groupsNone fitparams
Run fit with all sets of parameters
Parameters
Xarraylike shape nsamples nfeatures Training vector where nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples or nsamples noutput optional Target relative to X for classification or regression None for unsupervised learning
groups arraylike with shape nsamples optional Group labels for the samples used while splitting the dataset into traintest set Only used in conjunction with a "Group" cv instance eg GroupKFold
fitparams dict of string object Parameters passed to the fit method of the estima tor
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators

Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfXt
Call inversetransform on the estimator with the best found params
Only available if the underlying estimator implements inversetransform andrefitTrue
Parameters
Xtindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictselfX
Call predict on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predict
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictlogproba selfX
Call predictlogproba on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predictlogproba
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictproba selfX
Call predictproba on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predictproba
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
scoreselfXyNone
Returns the score on the given data if the estimator has been refit
This uses the score defined by scoring where provided and the bestestimatorscore method
otherwise
Parameters
Xarraylike shape nsamples nfeatures Input data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike shape nsamples or nsamples noutput optional Target relative to X
for classification or regression None for unsupervised learning
Returns
score float
setparams selfparams
Set the parameters of this estimator

The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object

Returns

self

transform selfX

Call transform on the estimator with the best found parameters

Only available if the underlying estimator supports transform andrefitTrue

Parameters

Xindexable length nsamples Must fulfill the input assumptions of the underlying esti mator

Examples using sklearnmodelselectionGridSearchCV

•Comparison of kernel ridge regression and SVR
•Faces recognition example using eigenfaces and SVMs
•Feature agglomeration vs univariate selection
•Concatenating multiple feature extraction methods
•Pipelining chaining a PCA and a logistic regression
•Column Transformer with Mixed Types

sklearnmodelselection ParameterGrid
classsklearnmodelselection ParameterGrid paramgrid
Grid of parameters with a discrete number of values for each
Can be used to iterate over parameter value combinations with the Python builtin function iter
Read more in the User Guide
Parameters
paramgrid dict of string to sequence or sequence of such The parameter grid to explore as
a dictionary mapping estimator parameters to sequences of allowed values
An empty dict signifies default parameters
A sequence of dicts signifies a sequence of grids to search and is useful to avoid exploring
parameter combinations that make no sense or have no effect See the examples below
See also
GridSearchCV UsesParameterGrid to perform a full parallelized parameter search
Examples
 from sklearnmodelselection import ParameterGrid
paramgrid a 1 2 b TrueFalse
listParameterGridparamgrid
a 1 b True a 1 b False
 a 2 b True a 2 b False

init selfparamgrid
sklearnmodelselection ParameterSampler
classsklearnmodelselection ParameterSampler paramdistributions niter ran
domstateNone
Generator on parameters sampled from given distributions
Nondeterministic iterable over random candidate combinations for hyper parameter search If all parameters
are presented as a list sampling without replacement is performed If at least one parameter is given as a
distribution sampling with replacement is used It is highly recommended to use continuous distributions for
continuous parameters
Note that before SciPy 016 the scipystatsdistributions do not accept a custom RNG instance
and always use the singleton RNG from numpyrandom Hence setting randomstate will not guarantee
a deterministic iteration whenever scipystats distributions are used to define the parameter search space
Deterministic behavior is however guaranteed from SciPy 016 onwards

scikitlearn user guide Release 0213
Read more in the User Guide
Parameters
paramdistributions dict Dictionary where the keys are parameters and values are distribu
tions from which a parameter is to be sampled Distributions either have to provide a rvs
function to sample from them or can be given as a list of values where a uniform distribu
tion is assumed
niter integer Number of parameter settings that are produced
randomstate int RandomState instance or None optional defaultNone Pseudo random
number generator state used for random uniform sampling from lists of possible values
instead of scipystats distributions If int randomstate is the seed used by the random
number generator If RandomState instance randomstate is the random number generator
If None the random number generator is the RandomState instance used by nprandom
Returns
params dict of string to any Yields dictionaries mapping each estimator parameter to as sam
pled value
Examples

Randomized search on hyper parameters
RandomizedSearchCV implements a "fit" and a "score" method It also implements "predict" "predictproba"
"decisionfunction" "transform" and "inversetransform" if they are implemented in the estimator used

The parameters of the estimator used to apply these methods are optimized by crossvalidated search over parameter settings
In contrast to GridSearchCV not all parameter values are tried out but rather a fixed number of parameter settings is sampled from the specified distributions The number of parameter settings that are tried is given by niter
If all parameters are presented as a list sampling without replacement is performed If at least one parameter is given as a distribution sampling with replacement is used It is highly recommended to use continuous distributions for continuous parameters
Note that before SciPy 016 the scipystatsdistributions do not accept a custom RNG instance and always use the singleton RNG from numpyrandom Hence setting randomstate will not guarantee a deterministic iteration whenever scipystats distributions are used to define the parameter search space
Read more in the User Guide
Parameters
estimator estimator object A object of that type is instantiated for each grid point This is assumed to implement the scikitlearn estimator interface Either estimator needs to provide ascore function or scoring must be passed
paramdistributions dict Dictionary with parameters names string as keys and distributions or lists of parameters to try Distributions must provide a rvs method for sampling such as those from scipystatsdistributions If a list is given it is sampled uniformly
niter int default10 Number of parameter settings that are sampled niter trades off runtime vs quality of the solution
scoring string callable listtuple dict or None default None A single string see The scoring parameter defining model evaluation rules or a callable see Defining your scoring strategy from metric functions to evaluate the predictions on the test set
For evaluating multiple metrics either give a list of unique strings or a dict with names as keys and callables as values
NOTE that when using custom scorers each scorer should return a single value Metric functions returning a listarray of values can be wrapped into multiple scorers that return one value each
SeeSpecifying multiple metrics for evaluation for an example
If None the estimator’s score method is used
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
predispatch int or string optional Controls the number of jobs that get dispatched during parallel execution Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process This parameter can be
• None in which case all the jobs are immediately created and spawned Use this for lightweight and fastrunning jobs to avoid delays due to ondemand spawning of the jobs
• An int giving the exact number of total jobs that are spawned
• A string giving an expression as a function of njobs as in ‘2njobs’

iidboolean default'warn' If True return the average score across folds weighted by the number of samples in each test set In this case the data is assumed to be identically distributed across the folds and the loss minimized is the total loss per sample and not the mean loss across the folds If False return the average score across folds Default is True but will change to False in version 022 to correspond to the standard definition of cross validation
Changed in version 020 Parameter iid will change from True to False by default in version 022 and will be removed in 024
cvint crossvalidation generator or an iterable optional Determines the crossvalidation splitting strategy Possible inputs for cv are
• None to use the default 3fold cross validation
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if the estimator is a classifier and yis either binary or multiclass StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
refit boolean string or callable defaultTrue Refit an estimator using the best found parameters on the whole dataset
For multiple metric evaluation this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end
Where there are considerations other than maximum score in choosing a best estimator refit can be set to a function which returns the selected bestindex given the cvresults
The refitted estimator is made available at the bestestimator attribute and permits usingpredict directly on this RandomizedSearchCV instance
Also for multiple metric evaluation the attributes bestindex bestscore and bestparams will only be available if refit is set and all of them will be determined wrt this specific scorer When refit is callable bestscore is disabled
Seescoring parameter to know more about multiple metric evaluation
Changed in version 020 Support for callable added
verbose integer Controls the verbosity the higher the more messages
randomstate int RandomState instance or None optional defaultNone Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipystats distributions If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
errorscore 'raise' or numeric Value to assign to the score if an error occurs in estimator fitting If set to 'raise' the error is raised If a numeric value is given FitFailedWarning is raised This parameter does not affect the refit step which will always raise the error Default is 'raise' but from version 022 it will change to npnan

returntrainscore boolean defaultFalse If False thecvresults attribute will not
include training scores Computing training scores is used to get insights on how differ
ent parameter settings impact the overfittingunderfitting tradeoff However computing the
scores on the training set can be computationally expensive and is not strictly required to
select the parameters that yield the best generalization performance
Attributes
cvresults dict of numpy masked ndarrays A dict with keys as column headers and values
as columns that can be imported into a pandas DataFrame
For instance the below given table
paramkernel paramgamma split0testscore ranktestscore
'rbf' 01 080 2
'rbf' 02 090 1
'rbf' 03 070 1
will be represented by a cvresults dict of

paramkernel maskedarraydata rbf rbf rbf
mask False
paramgamma maskedarraydata 01 02 03 mask False
split0testscore 080 090 070
split1testscore 082 050 070
meantestscore 081 070 070
stdtestscore 001 020 000
ranktestscore 3 1 1
split0trainscore 080 092 070
split1trainscore 082 055 070
meantrainscore 081 074 070
stdtrainscore 001 019 000
meanfittime 073 063 043
stdfittime 001 002 001
meanscoretime 001 006 004
stdscoretime 000 000 000
params kernel rbf gamma 01

NOTE
The keyparams is used to store a list of parameter settings dicts for all the parameter
candidates
Themeanfittime stdfittime meanscoretime and
stdscoretime are all in seconds
For multimetric evaluation the scores for all the scorers are available in the
cvresults dict at the keys ending with that scorer's name scorername
instead ofscore shown above 'split0testprecision' 'meantrainprecision' etc
bestestimator estimator or dict Estimator that was chosen by the search ie estimator
which gave highest score or smallest loss if specified on the left out data Not available if
refitFalse
For multimetric evaluation this attribute is present only if refit is specified
Seerefit parameter for more information on allowed values

bestscore float Mean crossvalidated score of the bestestimator
For multimetric evaluation this is not available if refit isFalse Seerefit parameter
for more information
bestparams dict Parameter setting that gave the best results on the hold out data
For multimetric evaluation this is not available if refit isFalse Seerefit parameter
for more information
bestindex int The index of the cvresults arrays which corresponds to the best can
didate parameter setting
The dict at searchcvresultsparamssearchbestindex gives
the parameter setting for the best model that gives the highest mean score search
bestscore
For multimetric evaluation this is not available if refit isFalse Seerefit parameter
for more information
scorer function or a dict Scorer function used on the held out data to choose the best param
eters for the model
For multimetric evaluation this attribute holds the validated scoring dict which maps
the scorer key to the scorer callable
nsplits int The number of crossvalidation splits foldsiterations
refittime float Seconds used for refitting the best model on the whole dataset
This is present only if refit is not False
See also
GridSearchCV Does exhaustive search over a grid of parameters
ParameterSampler A generator over parameter settings constructed from paramdistributions
Notes
The parameters selected are those that maximize the score of the heldout data according to the scoring param
eter
Ifnjobs was set to a value higher than one the data is copied for each parameter settingand not njobs times
This is done for efficiency reasons if individual jobs take very little time but may raise errors if the dataset
is large and not enough memory is available A workaround in this case is to set predispatch Then
the memory is copied only predispatch many times A reasonable value for predispatch is2
njobs
Methods
decisionfunction self X Call decisionfunction on the estimator with the best
found parameters
fitself X y groups Run fit with all sets of parameters
getparams self deep Get parameters for this estimator
inversetransform self Xt Call inversetransform on the estimator with the best
found params
Continued on next page

Table 6206 – continued from previous page
predict self X Call predict on the estimator with the best found param
eters
predictlogproba self X Call predictlogproba on the estimator with the best
found parameters
predictproba self X Call predictproba on the estimator with the best found
parameters
score self X y Returns the score on the given data if the estimator has
been refit
setparams self params Set the parameters of this estimator
transform self X Call transform on the estimator with the best found pa
rameters
init selfestimator paramdistributions niter10 scoringNone njobsNone iid'warn'
refitTrue cv'warn' verbose0 predispatch'2njobs' randomstateNone
errorscore'raisedeprecating' returntrainscoreFalse
decisionfunction selfX
Call decisionfunction on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports decisionfunction
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
fitselfXyNone groupsNone fitparams
Run fit with all sets of parameters
Parameters
Xarraylike shape nsamples nfeatures Training vector where nsamples is the
number of samples and nfeatures is the number of features
yarraylike shape nsamples or nsamples noutput optional Target relative to X
for classification or regression None for unsupervised learning
groups arraylike with shape nsamples optional Group labels for the samples used
while splitting the dataset into traintest set Only used in conjunction with a "Group" cv
instance eg GroupKFold
fitparams dict of string object Parameters passed to the fit method of the estima
tor
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfXt
Call inversetransform on the estimator with the best found params
Only available if the underlying estimator implements inversetransform andrefitTrue
Parameters

Xtindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictselfX
Call predict on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predict
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictlogproba selfX
Call predictlogproba on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predictlogproba
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
predictproba selfX
Call predictproba on the estimator with the best found parameters
Only available if refitTrue and the underlying estimator supports predictproba
Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
scoreselfXyNone
Returns the score on the given data if the estimator has been refit
This uses the score defined by scoring where provided and the bestestimatorscore method
otherwise
Parameters
Xarraylike shape nsamples nfeatures Input data where nsamples is the number
of samples and nfeatures is the number of features
yarraylike shape nsamples or nsamples noutput optional Target relative to X
for classification or regression None for unsupervised learning
Returns
score float
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Call transform on the estimator with the best found parameters
Only available if the underlying estimator supports transform andrefitTrue

Parameters
Xindexable length nsamples Must fulfill the input assumptions of the underlying esti
mator
Examples using sklearnmodelselectionRandomizedSearchCV
•Comparing randomized search and grid search for hyperparameter estimation
modelselectionfitgridpoint X y
Run fit on one set of parameters
sklearnmodelselection fitgridpoint
sklearnmodelselection fitgridpoint Xyestimator parameters train testscorer
verbose errorscore'raisedeprecating'
fitparams
Run fit on one set of parameters
Parameters
Xarraylike sparse matrix or list Input data
yarraylike or None Targets for input data
estimator estimator object A object of that type is instantiated for each grid point This is
assumed to implement the scikitlearn estimator interface Either estimator needs to provide
ascore function or scoring must be passed
parameters dict Parameters to be set on estimator for this grid point
train ndarray dtype int or bool Boolean mask or indices for training set
test ndarray dtype int or bool Boolean mask or indices for test set
scorer callable or None The scorer callable object function must have its signature as
scorerestimator X y
IfNone the estimator's score method is used
verbose int Verbosity level
fitparams kwargs Additional parameter passed to the fit function of the estimator
errorscore 'raise' or numeric Value to assign to the score if an error occurs in estimator
fitting If set to 'raise' the error is raised If a numeric value is given FitFailedWarning
is raised This parameter does not affect the refit step which will always raise the error
Default is 'raise' but from version 022 it will change to npnan
Returns
score float Score of this parameter setting on given test split
parameters dict The parameters that have been evaluated
nsamplestest int Number of test samples in this split

modelselectioncrossvalidate estimator

Read more in the User Guide
Parameters
estimator estimator object implementing 'fit' The object to use to fit the data
Xarraylike The data to fit Can be for example a list or an array
yarraylike optional default None The target variable to try to predict in the case of super
vised learning
groups arraylike with shape nsamples optional Group labels for the samples used while
splitting the dataset into traintest set Only used in conjunction with a "Group" cvinstance
egGroupKFold
scoring string callable listtuple dict or None default None A single string see The scoring
parameter defining model evaluation rules or a callable see Defining your scoring strategy
from metric functions to evaluate the predictions on the test set
For evaluating multiple metrics either give a list of unique strings or a dict with names as
keys and callables as values
NOTE that when using custom scorers each scorer should return a single value Metric
functions returning a listarray of values can be wrapped into multiple scorers that return
one value each
SeeSpecifying multiple metrics for evaluation for an example
If None the estimator's score method is used
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold cross validation
• integer to specify the number of folds in a StratifiedKFold
•CV splitter

• An iterable yielding train test splits as arrays of indices
For integerNone inputs if the estimator is a classifier and yis either binary or multiclass
StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
njobs int or None optional defaultNone The number of CPUs to use to do the computa
tionNone means 1 unless in a joblibparallelbackend context1means using
all processors See Glossary for more details
verbose integer optional The verbosity level
fitparams dict optional Parameters to pass to the fit method of the estimator
predispatch int or string optional Controls the number of jobs that get dispatched during
parallel execution Reducing this number can be useful to avoid an explosion of memory
consumption when more jobs get dispatched than CPUs can process This parameter can
be
• None in which case all the jobs are immediately created and spawned Use this for
lightweight and fastrunning jobs to avoid delays due to ondemand spawning of the jobs
• An int giving the exact number of total jobs that are spawned
• A string giving an expression as a function of njobs as in ‘2njobs’
returntrainscore boolean defaultFalse Whether to include train scores Computing train
ing scores is used to get insights on how different parameter settings impact the overfit
tingunderfitting tradeoff However computing the scores on the training set can be com
putationally expensive and is not strictly required to select the parameters that yield the best
generalization performance
returnestimator boolean default False Whether to return the estimators fitted on each split
errorscore ‘raise’ ‘raisedeprecating’ or numeric Value to assign to the score if an error
occurs in estimator fitting If set to ‘raise’ the error is raised If set to ‘raisedeprecating’
a FutureWarning is printed before the error is raised If a numeric value is given FitFailed
Warning is raised This parameter does not affect the refit step which will always raise the
error Default is ‘raisedeprecating’ but from version 022 it will change to npnan
Returns
scores dict of float arrays of shapensplits Array of scores of the estimator for each run of
the cross validation
A dict of arrays containing the scoretime arrays for each scorer is returned The possible
keys for this dict are
testscore The score array for test scores on each cv split
trainscore The score array for train scores on each cv split This is available
only ifreturntrainscore parameter is True
fittime The time for fitting the estimator on the train set for each cv split
scoretime The time for scoring the estimator on the test set for each cv
split Note time for scoring on the train set is not included even if
returntrainscore is set toTrue

```
Generate crossvalidated estimates for each input data point
The data is split according to the cv parameter Each sample belongs to exactly one test set and its prediction is
computed with an estimator fitted on the corresponding training set
Passing these predictions into an evaluation metric may not be a valid way to measure generalization perfor
mance Results can differ from crossvalidate andcrossvalscore unless all tests sets have equal
size and the metric decomposes over samples

Read more in the User Guide
Parameters
estimator estimator object implementing ‘fit’ and ‘predict’ The object to use to fit the data
Xarraylike The data to fit Can be for example a list or an array at least 2d
yarraylike optional default None The target variable to try to predict in the case of super vised learning
groups arraylike with shape nsamples optional Group labels for the samples used while splitting the dataset into traintest set Only used in conjunction with a “Group” cvinstance egGroupKFold
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split ting strategy Possible inputs for cv are

splitting the dataset into traintest set Only used in conjunction with a “Group” cvinstance
egGroupKFold
626sklearnmodelselection Model Selection 2117

trainsizes arraylike shape nticks dtype float or int Relative or absolute numbers of training examples that will be used to generate the learning curve If the dtype is float it is regarded as a fraction of the maximum size of the training set that is determined by the selected validation method ie it has to be within 0 1 Otherwise it is interpreted as absolute sizes of the training sets Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class default nplinspace01 10 5
cvint crossvalidation generator or an iterable optional Determines the crossvalidation splitting strategy Possible inputs for cv are
• None to use the default 3fold cross validation
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if the estimator is a classifier and yis either binary or multiclass StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
scoring string callable or None optional default None A string see model evaluation documentation or a scorer callable object function with signature scorerestimator X y
exploitincrementallearning boolean optional default False If the estimator supports incremental learning this will be used to speed up fitting for different training set sizes
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
predispatch integer or string optional Number of predispatched jobs for parallel execution default is all The option can reduce the allocated memory The string can be an expression like ‘2njobs’
verbose integer optional Controls the verbosity the higher the more messages
shuffle boolean optional Whether to shuffle training data before taking prefixes of it based on‘‘trainsizes‘‘
randomstate int RandomState instance or None optional defaultNone If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when shuffle is True
errorscore ‘raise’ ‘raisedeprecating’ or numeric Value to assign to the score if an error occurs in estimator fitting If set to ‘raise’ the error is raised If set to ‘raisedeprecating’ a FutureWarning is printed before the error is raised If a numeric value is given FitFailed Warning is raised This parameter does not affect the refit step which will always raise the error Default is ‘raisedeprecating’ but from version 022 it will change to npnan
Returns
trainsizesabs array shape nuniqueticks dtype int Numbers of training examples that has been used to generate the learning curve Note that the number of ticks might be less than nticks because duplicate entries will be removed

trainscores array shape nticks ncvfolds Scores on training sets
testscores array shape nticks ncvfolds Scores on test set

bose0 scoringNone
Evaluate the significance of a crossvalidated score with permutations
Read more in the User Guide
Parameters
estimator estimator object implementing 'fit' The object to use to fit the data
Xarraylike of shape at least 2D The data to fit
yarraylike The target variable to try to predict in the case of supervised learning
groups arraylike with shape nsamples optional Labels to constrain permutation within
groups ie yvalues are permuted among samples with the same group identifier When not
specifiedyvalues are permuted among all samples
When a grouped crossvalidator is used the group labels are also passed on to the split
method of the crossvalidator The crossvalidator uses them for grouping the samples while
splitting the dataset into traintest set
scoring string callable or None optional default None A single string see The scoring
parameter defining model evaluation rules or a callable see Defining your scoring strategy
from metric functions to evaluate the predictions on the test set
If None the estimator's score method is used
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold cross validation
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices

For integerNone inputs if the estimator is a classifier and yis either binary or multiclass
StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
npermutations integer optional Number of times to permute y
njobs int or None optional defaultNone The number of CPUs to use to do the computa
tionNone means 1 unless in a joblibparallelbackend context1means using
all processors See Glossary for more details
randomstate int RandomState instance or None optional default0 If int randomstate
is the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
verbose integer optional The verbosity level
Returns
score float The true score without permuting targets
permutationscores array shape npermutations The scores obtained for each permuta
tions
pvalue float The pvalue which approximates the probability that the score would be obtained
by chance This is calculated as
C 1 npermutations 1
Where C is the number of permutations whose score the true score
The best possible pvalue is 1npermutations 1 the worst is 10

Validation curve
Determine training and test scores for varying parameter values

Compute scores for an estimator with different values of a specified parameter This is similar to grid search with one parameter However this will also compute training scores and is merely a utility for plotting the results
Read more in the User Guide
Parameters
estimator object type that implements the “fit” and “predict” methods An object of that type which is cloned for each validation
Xarraylike shape nsamples nfeatures Training vector where nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples or nsamples nfeatures optional Target relative to X for classification or regression None for unsupervised learning
paramname string Name of the parameter that will be varied
paramrange arraylike shape nvalues The values of the parameter that will be evaluated
groups arraylike with shape nsamples optional Group labels for the samples used while splitting the dataset into traintest set Only used in conjunction with a “Group” cvinstance egGroupKFold
cvint crossvalidation generator or an iterable optional Determines the crossvalidation splitting strategy Possible inputs for cv are
• None to use the default 3fold cross validation
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if the estimator is a classifier and yis either binary or multiclass StratifiedKFold is used In all other cases KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
scoring string callable or None optional default None A string see model evaluation documentation or a scorer callable object function with signature scorerestimator X y
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
predispatch integer or string optional Number of predispatched jobs for parallel execution default is all The option can reduce the allocated memory The string can be an expression like ‘2njobs’
verbose integer optional Controls the verbosity the higher the more messages
errorscore ‘raise’ ‘raisedeprecating’ or numeric Value to assign to the score if an error occurs in estimator fitting If set to ‘raise’ the error is raised If set to ‘raisedeprecating’ a FutureWarning is printed before the error is raised If a numeric value is given FitFailed Warning is raised This parameter does not affect the refit step which will always raise the error Default is ‘raisedeprecating’ but from version 022 it will change to npnan
Returns

trainscores array shape nticks ncvfolds Scores on training sets
testscores array shape nticks ncvfolds Scores on test set

•Plotting Validation Curves
627sklearnmulticlass Multiclass and multilabel classification
6271 Multiclass and multilabel classification strategies
This module implements multiclass learning algorithms
• onevstherest onevsall
• onevsone
• error correcting output codes
The estimators provided in this module are metaestimators they require a base estimator to be provided in their constructor For example it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves
All classifiers in scikitlearn implement multiclass classification you only need to use this module if you want to experiment with custom multiclass strategies
The onevstherest metaclassifier also implements a predictproba method so long as such a method is implemented by the base classifier This method returns probabilities of class membership in both the single label and multilabel case Note that in the multilabel case probabilities are the marginal probability that a given sample falls in the given class As such in the multilabel case the sum of these probabilities over all possible labels for a given sample will not sum to unity as they do in the single label case
User guide See the Multiclass and multilabel algorithms section for further details
multiclassOneVsRestClassifier estimator
   Onevstherest OvR multiclassmultilabel strategy
multiclassOneVsOneClassifier estimator
   Onevsone multiclass strategy
multiclassOutputCodeClassifier estimator
   ErrorCorrecting OutputCode multiclass strategy
6272sklearnmulticlass OneVsRestClassifier
classsklearnmulticlass OneVsRestClassifier estimator njobsNone
Onevstherest OvR multiclassmultilabel strategy
Also known as onevsall this strategy consists in fitting one classifier per class For each classifier the class is

fitted against all the other classes In addition to its computational efficiency only nclasses classifiers are needed one advantage of this approach is its interpretability Since each class is represented by one and one classifier only it is possible to gain knowledge about the class by inspecting its corresponding classifier This is the most commonly used strategy for multiclass classification and is a fair default choice
This strategy can also be used for multilabel learning where a classifier is used to predict multiple labels for instance by fitting on a 2d matrix in which cell i j is 1 if sample i has label j and 0 otherwise
In the multilabel learning literature OvR is also known as the binary relevance method
Read more in the User Guide
Parameters
estimator estimator object An estimator object implementing fit and one of decisionfunction orpredictproba
njobs int or None optional defaultNone The number of jobs to use for the computation None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
Attributes
estimators list ofnclasses estimators Estimators used for predictions
classes array shape nclasses Class labels
labelbinarizer LabelBinarizer object Object used to transform multiclass labels to binary labels and viceversa
multilabel boolean Whether this is a multilabel classifier
Methods
decisionfunction self X Returns the distance of each sample from the decision boundary for each class
fitself X y Fit underlying estimators
getparams self deep Get parameters for this estimator
partialfit self X y classes Partially fit underlying estimators
predict self X Predict multiclass targets using underlying estimators
predictproba self X Probability estimates
score self X y sampleweight Returns the mean accuracy on the given test data and labels
setparams self params Set the parameters of this estimator
init selfestimator njobsNone
decisionfunction selfX
Returns the distance of each sample from the decision boundary for each class This can only be used with estimators which implement the decisionfunction method
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tarraylike shape nsamples nclasses
fitselfXy

Fit underlying estimators
Parameters
Xsparse arraylike shape nsamples nfeatures Data
ysparse arraylike shape nsamples nsamples nclasses Multiclass targets
An indicator matrix turns on multilabel classification
Returns
self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
multilabel
Whether this is a multilabel classifier
partialfit selfXyclassesNone
Partially fit underlying estimators
Should be used when memory is inefficient to train all data Chunks of data can be passed in several
iteration
Parameters
Xsparse arraylike shape nsamples nfeatures Data
ysparse arraylike shape nsamples nsamples nclasses Multiclass targets
An indicator matrix turns on multilabel classification
classes array shape nclasses Classes across all calls to partialfit Can be obtained
vianpuniqueyall where yall is the target vector of the entire dataset This
argument is only required in the first call of partialfit and can be omitted in the subsequent
calls
Returns
self
predictselfX
Predict multiclass targets using underlying estimators
Parameters
Xsparse arraylike shape nsamples nfeatures Data
Returns
ysparse arraylike shape nsamples nsamples nclasses Predicted multiclass
targets
predictproba selfX
Probability estimates
The returned estimates for all classes are ordered by label of classes

Note that in the multilabel case each sample can have any number of labels This returns the marginal probability that the given sample has the label in question For example it is entirely consistent that two labels both have a 90 probability of applying to a given sample
In the single label multiclass case the rows of the returned matrix sum to 1
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tsparse arraylike shape nsamples nclasses Returns the probability of the sample for each class in the model where classes are ordered as they are in selfclasses
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
Examples using sklearnmulticlassOneVsRestClassifier
•Multilabel classification
•Receiver Operating Characteristic ROC
•PrecisionRecall
•Classifier Chain
6273sklearnmulticlass OneVsOneClassifier
classsklearnmulticlass OneVsOneClassifier estimator njobsNone
Onevsone multiclass strategy
This strategy consists in fitting one classifier per class pair At prediction time the class which received the most votes is selected Since it requires to fit nclasses nclasses 1 2 classifiers this method is usually slower than onevstherest due to its Onclasses2 complexity However this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with nsamples This is because

each individual learning problem only involves a small subset of the data whereas with onevstherest the complete dataset is used nclasses times
Read more in the User Guide
Parameters
estimator estimator object An estimator object implementing fit and one of decisionfunction orpredictproba
njobs int or None optional defaultNone The number of jobs to use for the computation None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
Attributes
estimators list ofnclasses nclasses 1 2 estimators Estimators used for predictions
classes numpy array of shape nclasses Array containing labels
pairwiseindices list length lenestimators orNone Indices of samples used when training the estimators None whenestimator does not have pairwise at tribute
Methods
decisionfunction self X Decision function for the OneVsOneClassifier
fitself X y Fit underlying estimators
getparams self deep Get parameters for this estimator
partialfit self X y classes Partially fit underlying estimators
predict self X Estimate the best class label for each sample in X
score self X y sampleweight Returns the mean accuracy on the given test data and labels
setparams self params Set the parameters of this estimator
init selfestimator njobsNone
decisionfunction selfX
Decision function for the OneVsOneClassifier
The decision values for the samples are computed by adding the normalized sum of pairwise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie
Parameters
Xarraylike shape nsamples nfeatures
Returns
Yarraylike shape nsamples nclasses
fitselfXy
Fit underlying estimators
Parameters
Xsparse arraylike shape nsamples nfeatures Data
yarraylike shape nsamples Multiclass targets

Returns
self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone
Partially fit underlying estimators
Should be used when memory is inefficient to train all data Chunks of data can be passed in several
iteration where the first call should have an array of all target variables
Parameters
Xsparse arraylike shape nsamples nfeatures Data
yarraylike shape nsamples Multiclass targets
classes array shape nclasses Classes across all calls to partialfit Can be obtained
vianpuniqueyall where yall is the target vector of the entire dataset This
argument is only required in the first call of partialfit and can be omitted in the subsequent
calls
Returns
self
predictselfX
Estimate the best class label for each sample in X
This is implemented as argmaxdecisionfunctionX axis1 which will return the label
of the class with most votes by estimators predicting the outcome of a decision for each possible class pair
Parameters
Xsparse arraylike shape nsamples nfeatures Data
Returns
ynumpy array of shape nsamples Predicted multiclass targets
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
627sklearnmulticlass Multiclass and multilabel classification 2127

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
6274sklearnmulticlass OutputCodeClassifier
classsklearnmulticlass OutputCodeClassifier estimator codesize15 ran
domstateNone njobsNone
ErrorCorrecting OutputCode multiclass strategy
Outputcode based strategies consist in representing each class with a binary code an array of 0s and 1s At
fitting time one binary classifier per bit in the code book is fitted At prediction time the classifiers are used to
project new points in the class space and the class closest to the points is chosen The main advantage of these
strategies is that the number of classifiers used can be controlled by the user either for compressing the model
0 codesize 1 or for making the model more robust to errors codesize 1 See the documentation for
more details
Read more in the User Guide
Parameters
estimator estimator object An estimator object implementing fit and one of
decisionfunction orpredictproba
codesize float Percentage of the number of classes to be used to create the code book A num
ber between 0 and 1 will require fewer classifiers than onevstherest A number greater
than 1 will require more classifiers than onevstherest
randomstate int RandomState instance or None optional default None The generator
used to initialize the codebook If int randomstate is the seed used by the random number
generator If RandomState instance randomstate is the random number generator If None
the random number generator is the RandomState instance used by nprandom
njobs int or None optional defaultNone The number of jobs to use for the computation
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
Attributes
estimators list ofintnclasses codesize estimators Estimators used for pre
dictions
classes numpy array of shape nclasses Array containing labels
codebook numpy array of shape nclasses codesize Binary array containing the code of
each class

628sklearnmultioutput Multioutput regression and classifica
tion
This module implements multioutput regression and classification
The estimators provided in this module are metaestimators they require a base estimator to be provided in their
constructor The metaestimator extends single output estimators to multioutput estimators
User guide See the Multiclass and multilabel algorithms section for further details
multioutputClassifierChain baseestimator A multilabel model that arranges binary classifiers into a
chain
multioutputMultiOutputRegressor estimator Multi target regression
multioutputMultiOutputClassifier estimator Multi target classification
multioutputRegressorChain baseestimator
   A multilabel model that arranges regressions into a chain
6281sklearnmultioutput ClassifierChain
classsklearnmultioutput ClassifierChain baseestimator orderNone cvNone ran
domstateNone
A multilabel model that arranges binary classifiers into a chain
Each model makes a prediction in the order specified by the chain using all of the available features provided to
the model plus the predictions of models that are earlier in the chain
Read more in the User Guide
Parameters
baseestimator estimator The base estimator from which the classifier chain is built
order arraylike shapenoutputs or ‘random’ optional By default the order will be deter
mined by the order of columns in the label matrix Y
order 0 1 2 Yshape1 1
The order of the chain can be explicitly set by providing a list of integers For example for
a chain of length 5
order 1 3 2 4 0
means that the first model in the chain will make predictions for column 1 in the Y matrix
the second model will make predictions for column 3 etc

If order is ‘random’ a random ordering will be used
cvint crossvalidation generator or an iterable optional defaultNone Determines whether
to use cross validated predictions or true labels for the results of previous estimators in the
chain If cv is None the true labels are used when fitting Otherwise possible inputs for cv
are
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
The random number generator is used to generate random chain orders
Attributes
classes list A list of arrays of length lenestimators containing the class labels for
each estimator in the chain
estimators list A list of clones of baseestimator
order list The order of labels in the classifier chain
See also
RegressorChain Equivalent for regression
MultioutputClassifier Classifies each output independently rather than chaining

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnmultioutputClassifierChain
•Classifier Chain
6282sklearnmultioutput MultiOutputRegressor
classsklearnmultioutput MultiOutputRegressor estimator njobsNone
Multi target regression
This strategy consists of fitting one regressor per target This is a simple strategy for extending regressors that
do not natively support multitarget regression
Parameters
estimator estimator object An estimator object implementing fit andpredict
njobs int or None optional defaultNone The number of jobs to run in parallel for fit
None means 1 unless in a joblibparallelbackend context1means using all
processors See Glossary for more details
When individual estimators are fast to train or predict using njobs1 can result in slower
performance due to the overhead of spawning processes
Attributes
estimators list ofnoutput estimators Estimators used for predictions
Methods
fitself X y sampleweight Fit the model to data
getparams self deep Get parameters for this estimator
partialfit self X y sampleweight Incrementally fit the model to data
predict self X Predict multioutput variable using a model trained for
each target variable
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfestimator njobsNone
fitselfXysampleweightNone
Fit the model to data Fit a separate model for each output variable

Parameters
Xsparse arraylike shape nsamples nfeatures Data
ysparse arraylike shape nsamples noutputs Multioutput targets An indicator ma
trix turns on multilabel estimation
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Only supported if the underlying regressor supports sample
weights
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXysampleweightNone
Incrementally fit the model to data Fit a separate model for each output variable
Parameters
Xsparse arraylike shape nsamples nfeatures Data
ysparse arraylike shape nsamples noutputs Multioutput targets
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Only supported if the underlying regressor supports sample
weights
Returns
self object
predictselfX
Predict multioutput variable using a model trained for each target variable
Parameters
Xsparse arraylike shape nsamples nfeatures Data
Returns
ysparse arraylike shape nsamples noutputs Multioutput targets predicted across
multiple predictors Note Separate models are generated for each predictor
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the regression sum of squares ytrue ytruemean 2sum Best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters

Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
R2 is calculated by weighting all the targets equally using multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

classes list of numpy arrays shape noutputs Each array is unique classes for one output
in strint Can be obtained by via npuniquey i for i in rangey
shape1 where y is the target matrix of the entire dataset This argument is required
for the first call to partialfit and can be omitted in the subsequent calls Note that y doesn’t
need to contain all labels in classes
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Only supported if the underlying regressor supports sample
weights
Returns
self object
predictselfX

Predict multioutput variable using a model trained for each target variable
Parameters
Xsparse arraylike shape nsamples nfeatures Data
Returns
ysparse arraylike shape nsamples noutputs Multioutput targets predicted across
multiple predictors Note Separate models are generated for each predictor
predictproba selfX
Probability estimates Returns prediction probabilities for each class of each output
This method will raise a ValueError if any of the estimators do not have predictproba
Parameters
Xarraylike shape nsamples nfeatures Data
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs
1 The class probabilities of the input samples The order of the classes corresponds to
that in the attribute classes
scoreselfXy
Returns the mean accuracy on the given test data and labels
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples noutputs True values for X
Returns
scores float accuracyscore of selfpredictX versus y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
6284sklearnmultioutput RegressorChain
classsklearnmultioutput RegressorChain baseestimator orderNone cvNone ran
domstateNone
A multilabel model that arranges regressions into a chain
Each model makes a prediction in the order specified by the chain using all of the available features provided to
the model plus the predictions of models that are earlier in the chain
Read more in the User Guide
Parameters
baseestimator estimator The base estimator from which the classifier chain is built

order arraylike shapenoutputs or ‘random’ optional By default the order will be deter
mined by the order of columns in the label matrix Y
order 0 1 2 Yshape1 1
The order of the chain can be explicitly set by providing a list of integers For example for
a chain of length 5
order 1 3 2 4 0
means that the first model in the chain will make predictions for column 1 in the Y matrix
the second model will make predictions for column 3 etc
If order is ‘random’ a random ordering will be used
cvint crossvalidation generator or an iterable optional defaultNone Determines whether
to use cross validated predictions or true labels for the results of previous estimators in the
chain If cv is None the true labels are used when fitting Otherwise possible inputs for cv
are
• integer to specify the number of folds in a StratifiedKFold
•CV splitter
• An iterable yielding train test splits as arrays of indices
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
The random number generator is used to generate random chain orders
Attributes
estimators list A list of clones of baseestimator
order list The order of labels in the classifier chain
See also
ClassifierChain Equivalent for classification
MultioutputRegressor Learns each output independently rather than chaining
Methods
fitself X Y Fit the model to data matrix X and targets Y
getparams self deep Get parameters for this estimator
predict self X Predict on the data matrix X using the ClassifierChain
model
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfbaseestimator orderNone cvNone randomstateNone
fitselfXY
Fit the model to data matrix X and targets Y

Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
Yarraylike shape nsamples nclasses The target values
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict on the data matrix X using the ClassifierChain model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
Returns
Ypred arraylike shape nsamples nclasses The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
629sklearnnaivebayes Naive Bayes
Thesklearnnaivebayes module implements Naive Bayes algorithms These are supervised learning methods based on applying Bayes’ theorem with strong naive feature independence assumptions
User guide See the Naive Bayes section for further details
naivebayesBernoulliNB alpha binarize Naive Bayes classifier for multivariate Bernoulli models
naivebayesGaussianNB priors varsmoothing Gaussian Naive Bayes GaussianNB

6291sklearnnaivebayes BernoulliNB
classsklearnnaivebayes BernoulliNB alpha10 binarize00 fitpriorTrue classpriorNone
Naive Bayes classifier for multivariate Bernoulli models
Like MultinomialNB this classifier is suitable for discrete data The difference is that while MultinomialNB works with occurrence counts BernoulliNB is designed for binaryboolean features
Read more in the User Guide
Parameters
alpha float optional default10 Additive LaplaceLidstone smoothing parameter 0 for no smoothing
binarize float or None optional default00 Threshold for binarizing mapping to booleans of sample features If None input is presumed to already consist of binary vectors
fitprior boolean optional defaultTrue Whether to learn class prior probabilities or not If false a uniform prior will be used
classprior arraylike sizenclasses optional defaultNone Prior probabilities of the classes If specified the priors are not adjusted according to the data
Attributes
classlogprior array shape nclasses Log probability of each class smoothed
featurelogprob array shape nclasses nfeatures Empirical log probability of fea tures given a class Pxiy
classcount array shape nclasses Number of samples encountered for each class during fitting This value is weighted by the sample weight when provided

featurecount array shape nclasses nfeatures Number of samples encountered for
each class feature during fitting This value is weighted by the sample weight when
provided

Methods
fitself X y sampleweight Fit Naive Bayes classifier according to X y
getparams self deep Get parameters for this estimator
partialfit self X y classes sampleweight Incremental fit on a batch of samples
predict self X Perform classification on an array of test vectors X
predictlogproba self X Return logprobability estimates for the test vector X
predictproba self X Return probability estimates for the test vector X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfalpha10 binarize00 fitpriorTrue classpriorNone
fitselfXysampleweightNone
Fit Naive Bayes classifier according to X y
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
sampleweight arraylike shape nsamples defaultNone Weights applied to indi
vidual samples 1 for unweighted

Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone sampleweightNone
Incremental fit on a batch of samples
This method is expected to be called several times consecutively on different chunks of a dataset so as to
implement outofcore or online learning
This is especially useful when the whole dataset is too big to fit in memory at once
This method has some performance overhead hence it is better to call partialfit on chunks of data that are
as large as possible as long as fitting in the memory budget to hide the overhead
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
classes arraylike shape nclasses defaultNone List of all the classes that can pos
sibly appear in the y vector
Must be provided at the first call to partialfit can be omitted in subsequent calls
sampleweight arraylike shape nsamples defaultNone Weights applied to indi
vidual samples 1 for unweighted
Returns
self object
predictselfX
Perform classification on an array of test vectors X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carray shape nsamples Predicted target values for X
predictlogproba selfX
Return logprobability estimates for the test vector X
Parameters
Xarraylike shape nsamples nfeatures
Returns

Carraylike shape nsamples nclasses Returns the logprobability of the samples
for each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
predictproba selfX
Return probability estimates for the test vector X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carraylike shape nsamples nclasses Returns the probability of the samples for
each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

init selfpriorsNone varsmoothing1e09
fitselfXysampleweightNone
Fit Gaussian Naive Bayes according to X y
Parameters

Xarraylike shape nsamples nfeatures Training vectors where nsamples is the num
ber of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
sampleweight arraylike shape nsamples optional defaultNone Weights applied
to individual samples 1 for unweighted
New in version 017 Gaussian Naive Bayes supports fitting with sampleweight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit selfXyclassesNone sampleweightNone
Incremental fit on a batch of samples
This method is expected to be called several times consecutively on different chunks of a dataset so as to
implement outofcore or online learning
This is especially useful when the whole dataset is too big to fit in memory at once
This method has some performance and numerical stability overhead hence it is better to call partialfit on
chunks of data that are as large as possible as long as fitting in the memory budget to hide the overhead
Parameters
Xarraylike shape nsamples nfeatures Training vectors where nsamples is the num
ber of samples and nfeatures is the number of features
yarraylike shape nsamples Target values
classes arraylike shape nclasses optional defaultNone List of all the classes that
can possibly appear in the y vector
Must be provided at the first call to partialfit can be omitted in subsequent calls
sampleweight arraylike shape nsamples optional defaultNone Weights applied
to individual samples 1 for unweighted
New in version 017
Returns
self object
predictselfX
Perform classification on an array of test vectors X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carray shape nsamples Predicted target values for X

predictlogproba selfX
Return logprobability estimates for the test vector X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carraylike shape nsamples nclasses Returns the logprobability of the samples
for each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
predictproba selfX
Return probability estimates for the test vector X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carraylike shape nsamples nclasses Returns the probability of the samples for
each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

6293sklearnnaivebayes MultinomialNB
classsklearnnaivebayes MultinomialNB alpha10 fitpriorTrue classpriorNone
Naive Bayes classifier for multinomial models
The multinomial Naive Bayes classifier is suitable for classification with discrete features eg word counts for text classification The multinomial distribution normally requires integer feature counts However in practice fractional counts such as tfidf may also work
Read more in the User Guide
Parameters
alpha float optional default10 Additive LaplaceLidstone smoothing parameter 0 for no smoothing
fitprior boolean optional defaultTrue Whether to learn class prior probabilities or not If false a uniform prior will be used
classprior arraylike size nclasses optional defaultNone Prior probabilities of the classes If specified the priors are not adjusted according to the data
Attributes
classlogprior array shape nclasses Smoothed empirical log probability for each class
intercept array shape nclasses Mirrors classlogprior for interpreting Multi nomialNB as a linear model
featurelogprob array shape nclasses nfeatures Empirical log probability of features given a class Pxiy
coef array shape nclasses nfeatures Mirrors featurelogprob for interpreting MultinomialNB as a linear model
classcount array shape nclasses Number of samples encountered for each class during fitting This value is weighted by the sample weight when provided
featurecount array shape nclasses nfeatures Number of samples encountered for each class feature during fitting This value is weighted by the sample weight when provided
Notes
For the rationale behind the names coef andintercept ie naive Bayes as a linear classifier see J Rennie et al 2003 Tackling the poor assumptions of naive Bayes text classifiers ICML

BallTree for fast generalized Npoint problems
BallTreeX leafsize40 metric’minkowski’ kwargs
Parameters
Xarraylike shape nsamples nfeatures nsamples is the number of points in the data
set and nfeatures is the dimension of the parameter space Note if X is a Ccontiguous
array of doubles then data will not be copied Otherwise an internal copy will be made
leafsize positive integer default 40 Number of points at which to switch to bruteforce
Changing leafsize will not affect the results of a query but can significantly impact the
speed of a query and the memory required to store the constructed tree The amount of
memory needed to store the tree scales as approximately nsamples leafsize For a spec
ifiedleafsize a leaf node is guaranteed to satisfy leafsize npoints
2leafsize except in the case that nsamples leafsize
metric string or DistanceMetric object the distance metric to use for the tree De
fault’minkowski’ with p2 that is a euclidean metric See the documentation of the
DistanceMetric class for a list of available metrics balltreevalidmetrics gives a list of the
metrics which are valid for BallTree
Additional keywords are passed to the distance metric class
Attributes
data memory view The training data
Examples

kerneldensity selfXhkernel'gaussian' atol0 rtol1E8 breadthfirstTrue re
turnlogFalse
Compute the kernel density estimate at points X with the given kernel using the distance metric specified
at tree creation
Parameters
Xarraylike shape nsamples nfeatures An array of points to query Last dimension
should match dimension of training data
hfloat the bandwidth of the kernel
kernel string specify the kernel to use Options are 'gaussian' 'tophat' 'epanechnikov'
 'exponential' 'linear' 'cosine' Default is kernel 'gaussian'
atol rtol float default 0 Specify the desired relative and absolute tolerance of the re
sult If the true result is Ktrue then the returned result Kret satisfies absKtrue
Kret atol rtol Kret The default is zero ie machine precision for
both
breadthfirst boolean default False if True use a breadthfirst search If False default
use a depthfirst search Breadthfirst is generally faster for compact kernels andor high
tolerances
returnlog boolean default False return the logarithm of the result This can be more
accurate than returning the result itself for narrow kernels
Returns
density ndarray The array of logdensity evaluations shape Xshape1
queryXk1returndistanceTrue dualtreeFalse breadthfirstFalse
query the tree for the k nearest neighbors
Parameters
Xarraylike shape nsamples nfeatures An array of points to query
kinteger default 1 The number of nearest neighbors to return
returndistance boolean default True if True return a tuple d i of distances and
indices if False return array i

dualtree boolean default False if True use the dual tree formalism for the query a tree
is built for the query points and the pair of trees is used to efficiently search this space
This can lead to better performance as the number of points grows large
breadthfirst boolean default False if True then query the nodes in a breadthfirst
manner Otherwise query the nodes in a depthfirst manner
sortresults boolean default True if True then distances and indices of each point are
sorted on return so that the first column contains the closest points Otherwise neighbors
are returned in an arbitrary order
Returns
iif returndistance False
di if returndistance True
darray of doubles shape xshape1 k each entry gives the list of distances to the
neighbors of the corresponding point
iarray of integers shape xshape1 k each entry gives the list of indices of neigh
bors of the corresponding point
queryradius
queryradiusself X r countonly False
query the tree for neighbors within a radius r
Parameters
Xarraylike shape nsamples nfeatures An array of points to query
rdistance within which neighbors are returned r can be a single value or an array of values
of shape xshape1 if different radii are desired for each point
returndistance boolean default False if True return distances to neighbors of each
point if False return only neighbors Note that unlike the query method setting re
turndistanceTrue here adds to the computation time Not all distances need to be
calculated explicitly for returndistanceFalse Results are not sorted by default see
sortresults keyword
countonly boolean default False if True return only the count of points within dis
tance r if False return the indices of all points within distance r If returndistanceTrue
setting countonlyTrue will result in an error
sortresults boolean default False if True the distances and indices will be sorted
before being returned If False the results will not be sorted If returndistance False
setting sortresults True will result in an error
Returns
count if countonly True
ind if countonly False and returndistance False
ind dist if countonly False and returndistance True
count array of integers shape Xshape1 each entry gives the number of neighbors
within a distance r of the corresponding point
ind array of objects shape Xshape1 each element is a numpy integer array listing
the indices of neighbors of the corresponding point Note that unlike the results of a k
neighbors query the returned neighbors are not sorted by distance by default

dist array of objects shape Xshape1 each element is a numpy double array listing
the distances corresponding to indices in i
twopointcorrelation
Compute the twopoint correlation function
Parameters
Xarraylike shape nsamples nfeatures An array of points to query Last dimension
should match dimension of training data
rarraylike A onedimensional array of distances
dualtree boolean default False If true use a dualtree algorithm Otherwise use a
singletree algorithm Dual tree algorithms can have better scaling for large N
Returns
counts ndarray countsi contains the number of pairs of points with distance less than or
equal to ri
6302sklearnneighbors DistanceMetric
classsklearnneighbors DistanceMetric
DistanceMetric class
This class provides a uniform interface to fast distance metric functions The various metrics can be accessed via
thegetmetric class method and the metric string identifier see below For example to use the Euclidean
distance
dist DistanceMetricgetmetriceuclidean
X 0 1 2
3 4 5
distpairwiseX
array 0 519615242
 519615242 0
Available Metrics
The following lists the string metric identifiers and the associated distance metric classes
Metrics intended for realvalued vector spaces

identifier class name args distance function
“euclidean” EuclideanDistance
•sqrtsumx
y2
“manhattan” ManhattanDistance
•sumx y
“chebyshev” ChebyshevDistance
•maxx y
“minkowski” MinkowskiDistance p sumx
yp1p
“wminkowski” WMinkowskiDistance p w sumwx
yp1p
“seuclidean” SEuclideanDistance V sqrtsumx
y2 V
“mahalanobis” MahalanobisDistance V or VI sqrtx y
V1 x y
Metrics intended for twodimensional vector spaces Note that the haversine distance metric requires data in the form of latitude longitude and both inputs and outputs are in units of radians
identifier class name distance function
“haver
sine”HaversineDis
tance2 arcsinsqrtsin205 dx
cosx1cosx2sin205 dy
Metrics intended for integervalued vector spaces Though intended for integervalued vectors these are also valid metrics in the case of realvalued vectors
identifier class name distance function
“hamming” HammingDistance Nunequalx y Ntot
“canberra” CanberraDistance sumx y x y
“braycurtis” BrayCurtisDistance sumx y sumx sumy
Metrics intended for booleanvalued vector spaces Any nonzero entry is evaluated to “True” In the listings below the following abbreviations are used
• N number of dimensions
• NTT number of dims in which both values are True
• NTF number of dims in which the first value is True second is False
• NFT number of dims in which the first value is False second is True
• NFF number of dims in which both values are False
• NNEQ number of nonequal dimensions NNEQ NTF NFT
• NNZ number of nonzero dimensions NNZ NTF NFT NTT

identifier class name distance function
“jaccard” JaccardDistance NNEQ NNZ
“matching” MatchingDistance NNEQ N
“dice” DiceDistance NNEQ NTT NNZ
“kulsinski” KulsinskiDistance NNEQ N NTT NNEQ N
“rogerstanimoto” RogersTanimotoDistance 2 NNEQ N NNEQ
“russellrao” RussellRaoDistance NNZ N
“sokalmichener” SokalMichenerDistance 2 NNEQ N NNEQ
“sokalsneath” SokalSneathDistance NNEQ NNEQ 05 NTT
Userdefined distance
identifier class name args
“pyfunc” PyFuncDistance func
Herefunc is a function which takes two onedimensional numpy arrays and returns a distance Note that
in order to be used within the BallTree the distance must be a true metric ie it must satisfy the following
properties
1 Nonnegativity dx y 0
2 Identity dx y 0 if and only if x y
3 Symmetry dx y dy x
4 Triangle Inequality dx y dy z dx z
Because of the Python object overhead involved in calling the python function this will be fairly slow but it
will have the same scaling as other distances
Methods
disttordist Convert the true distance to the reduced distance
getmetric Get the given distance metric from the string identifier
pairwise Compute the pairwise distances between X and Y
rdisttodist Convert the Reduced distance to the true distance
init selfargs kwargs
Initialize self See helptypeself for accurate signature
disttordist
Convert the true distance to the reduced distance
The reduced distance defined for some metrics is a computationally more efficient measure which pre
serves the rank of the true distance For example in the Euclidean distance metric the reduced distance is
the squaredeuclidean distance
getmetric
Get the given distance metric from the string identifier
See the docstring of DistanceMetric for a list of available metrics
Parameters
metric string or class name The distance metric to use

kwargs additional arguments will be passed to the requested metric
pairwise
Compute the pairwise distances between X and Y
This is a convenience routine for the sake of testing For many metrics the utilities in
scipyspatialdistancecdist and scipyspatialdistancepdist will be faster
Parameters
Xarraylike Array of shape Nx D representing Nx points in D dimensions
Yarraylike optional Array of shape Ny D representing Ny points in D dimensions
If not specified then YX
Returns
——
dist ndarray The shape Nx Ny array of pairwise distances between points in X and Y
rdisttodist
Convert the Reduced distance to the true distance
The reduced distance defined for some metrics is a computationally more efficient measure which pre
serves the rank of the true distance For example in the Euclidean distance metric the reduced distance is
the squaredeuclidean distance
6303sklearnneighbors KDTree
classsklearnneighbors KDTree
KDTree for fast generalized Npoint problems
KDTreeX leafsize40 metric’minkowski’ kwargs
Parameters
Xarraylike shape nsamples nfeatures nsamples is the number of points in the data
set and nfeatures is the dimension of the parameter space Note if X is a Ccontiguous
array of doubles then data will not be copied Otherwise an internal copy will be made
leafsize positive integer default 40 Number of points at which to switch to bruteforce
Changing leafsize will not affect the results of a query but can significantly impact the
speed of a query and the memory required to store the constructed tree The amount of
memory needed to store the tree scales as approximately nsamples leafsize For a spec
ifiedleafsize a leaf node is guaranteed to satisfy leafsize npoints
2leafsize except in the case that nsamples leafsize
metric string or DistanceMetric object the distance metric to use for the tree De
fault’minkowski’ with p2 that is a euclidean metric See the documentation of the
DistanceMetric class for a list of available metrics kdtreevalidmetrics gives a list of the
metrics which are valid for KDTree
Additional keywords are passed to the distance metric class
Attributes
data memory view The training data

Examples
Query for knearest neighbors
```
 import numpy as np
rng  nprandomRandomState0
X  rngrandomsample10 3  10 points in 3 dimensions
tree  KDTreeX leafsize2
dist ind  treequeryX1 k3
printind  indices of 3 closest neighbors
0 3 1
printdist  distances to 3 closest neighbors
 0 019662693 029473397
```
Pickle and Unpickle a tree Note that the state of the tree is saved in the pickle operation the tree needs not be rebuilt upon unpickling
```
 import numpy as np
 import pickle
rng  nprandomRandomState0
X  rngrandomsample10 3  10 points in 3 dimensions
tree  KDTreeX leafsize2
s  pickledumpstree
treecopy  pickleloadss
dist ind  treecopyqueryX1 k3
printind  indices of 3 closest neighbors
0 3 1
printdist  distances to 3 closest neighbors
 0 019662693 029473397
```
Query for neighbors within a given radius
```
 import numpy as np
rng  nprandomRandomState0
X  rngrandomsample10 3  10 points in 3 dimensions
tree  KDTreeX leafsize2
printtreequeryradiusX1 r03 countonly True

Compute the kernel density estimate at points X with the given kernel using the distance metric specified
at tree creation
Parameters
Xarraylike shape nsamples nfeatures An array of points to query Last dimension
should match dimension of training data
hfloat the bandwidth of the kernel
kernel string specify the kernel to use Options are 'gaussian' 'tophat' 'epanechnikov'
 'exponential' 'linear' 'cosine' Default is kernel 'gaussian'
atol rtol float default 0 Specify the desired relative and absolute tolerance of the re
sult If the true result is Ktrue then the returned result Kret satisfies absKtrue
Kret atol rtol Kret The default is zero ie machine precision for
both
breadthfirst boolean default False if True use a breadthfirst search If False default
use a depthfirst search Breadthfirst is generally faster for compact kernels andor high
tolerances
returnlog boolean default False return the logarithm of the result This can be more
accurate than returning the result itself for narrow kernels
Returns
density ndarray The array of logdensity evaluations shape Xshape1
queryXk1returndistanceTrue dualtreeFalse breadthfirstFalse
query the tree for the k nearest neighbors
Parameters
630sklearnneighbors Nearest Neighbors 2163

Xarraylike shape nsamples nfeatures An array of points to query
kinteger default 1 The number of nearest neighbors to return
returndistance boolean default True if True return a tuple d i of distances and
indices if False return array i
dualtree boolean default False if True use the dual tree formalism for the query a tree
is built for the query points and the pair of trees is used to efficiently search this space
This can lead to better performance as the number of points grows large
breadthfirst boolean default False if True then query the nodes in a breadthfirst
manner Otherwise query the nodes in a depthfirst manner
sortresults boolean default True if True then distances and indices of each point are
sorted on return so that the first column contains the closest points Otherwise neighbors
are returned in an arbitrary order
Returns
iif returndistance False
di if returndistance True
darray of doubles shape xshape1 k each entry gives the list of distances to the
neighbors of the corresponding point
iarray of integers shape xshape1 k each entry gives the list of indices of neigh
bors of the corresponding point
queryradius
queryradiusself X r countonly False
query the tree for neighbors within a radius r
Parameters
Xarraylike shape nsamples nfeatures An array of points to query
rdistance within which neighbors are returned r can be a single value or an array of values
of shape xshape1 if different radii are desired for each point
returndistance boolean default False if True return distances to neighbors of each
point if False return only neighbors Note that unlike the query method setting re
turndistanceTrue here adds to the computation time Not all distances need to be
calculated explicitly for returndistanceFalse Results are not sorted by default see
sortresults keyword
countonly boolean default False if True return only the count of points within dis
tance r if False return the indices of all points within distance r If returndistanceTrue
setting countonlyTrue will result in an error
sortresults boolean default False if True the distances and indices will be sorted
before being returned If False the results will not be sorted If returndistance False
setting sortresults True will result in an error
Returns
count if countonly True
ind if countonly False and returndistance False
ind dist if countonly False and returndistance True

count array of integers shape Xshape1 each entry gives the number of neighbors
within a distance r of the corresponding point
ind array of objects shape Xshape1 each element is a numpy integer array listing
the indices of neighbors of the corresponding point Note that unlike the results of a k
neighbors query the returned neighbors are not sorted by distance by default
dist array of objects shape Xshape1 each element is a numpy double array listing
the distances corresponding to indices in i
twopointcorrelation
Compute the twopoint correlation function
Parameters
Xarraylike shape nsamples nfeatures An array of points to query Last dimension
should match dimension of training data
rarraylike A onedimensional array of distances
dualtree boolean default False If true use a dualtree algorithm Otherwise use a
singletree algorithm Dual tree algorithms can have better scaling for large N
Returns
counts ndarray countsi contains the number of pairs of points with distance less than or
equal to ri
6304sklearnneighbors KernelDensity
classsklearnneighbors KernelDensity bandwidth10 algorithm’auto’ kernel’gaussian’
metric’euclidean’ atol0 rtol0 breadthfirstTrue
leafsize40 metricparamsNone
Kernel Density Estimation
Read more in the User Guide
Parameters
bandwidth float The bandwidth of the kernel
algorithm string The tree algorithm to use Valid options are ‘kdtree’’balltree’’auto’
Default is ‘auto’
kernel string The kernel to use Valid kernels are ‘gaus
sian’’tophat’’epanechnikov’’exponential’’linear’’cosine’ Default is ‘gaussian’
metric string The distance metric to use Note that not all metrics are valid with all algorithms
Refer to the documentation of BallTree andKDTree for a description of available algo
rithms Note that the normalization of the density output is correct only for the Euclidean
distance metric Default is ‘euclidean’
atol float The desired absolute tolerance of the result A larger tolerance will generally lead
to faster execution Default is 0
rtol float The desired relative tolerance of the result A larger tolerance will generally lead to
faster execution Default is 1E8
breadthfirst boolean If true default use a breadthfirst approach to the problem Otherwise
use a depthfirst approach
leafsize int Specify the leaf size of the underlying tree See BallTree orKDTree for
details Default is 40

metricparams dict Additional parameters to be passed to the tree for use with the metric
For more information see the documentation of BallTree orKDTree
Methods
fitself X y sampleweight Fit the Kernel Density model on the data
getparams self deep Get parameters for this estimator
sample self nsamples randomstate Generate random samples from the model
score self X y Compute the total log probability density under the
model
scoresamples self X Evaluate the density model on the data
setparams self params Set the parameters of this estimator
init selfbandwidth10 algorithm'auto' kernel'gaussian' metric'euclidean' atol0
rtol0 breadthfirstTrue leafsize40 metricparamsNone
fitselfXyNone sampleweightNone
Fit the Kernel Density model on the data
Parameters
Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
sampleweight arraylike shape nsamples optional List of sample weights attached
to the data X
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
sampleselfnsamples1 randomstateNone
Generate random samples from the model
Currently this is implemented only for gaussian and tophat kernels
Parameters
nsamples int optional Number of samples to generate Defaults to 1
randomstate int RandomState instance or None default to None If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
Returns
Xarraylike shape nsamples nfeatures List of samples
scoreselfXyNone
Compute the total log probability density under the model
Parameters

Xarraylike shape nsamples nfeatures List of nfeaturesdimensional data points
Each row corresponds to a single data point
Returns
logprob float Total loglikelihood of the data in X This is normalized to be a probability
density so the value will be low for highdimensional data
scoresamples selfX
Evaluate the density model on the data
Parameters
Xarraylike shape nsamples nfeatures An array of points to query Last dimension
should match dimension of training data nfeatures
Returns
density ndarray shape nsamples The array of logdensity evaluations These are nor
malized to be probability densities so values will be low for highdimensional data
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnneighborsKernelDensity
•Kernel Density Estimation
•Kernel Density Estimate of Species Distributions
•Simple 1D Kernel Density Estimation
6305sklearnneighbors KNeighborsClassifier
classsklearnneighbors KNeighborsClassifier nneighbors5 weights’uniform’ al
gorithm’auto’ leafsize30 p2met
ric’minkowski’ metricparamsNone
njobsNone kwargs
Classifier implementing the knearest neighbors vote
Read more in the User Guide
Parameters
nneighbors int optional default 5 Number of neighbors to use by default for
kneighbors queries
weights str or callable optional default ‘uniform’ weight function used in prediction Pos
sible values
• ‘uniform’ uniform weights All points in each neighborhood are weighted equally
• ‘distance’ weight points by the inverse of their distance in this case closer neighbors
of a query point will have a greater influence than neighbors which are further away

• callable a userdefined function which accepts an array of distances and returns an
array of the same shape containing the weights
algorithm ‘auto’ ‘balltree’ ‘kdtree’ ‘brute’ optional Algorithm used to compute the
nearest neighbors
• ‘balltree’ will use BallTree
• ‘kdtree’ will use KDTree
• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
tofit method
Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default 30 Leaf size passed to BallTree or KDTree This can affect
the speed of the construction and query as well as the memory required to store the tree
The optimal value depends on the nature of the problem
pinteger optional default 2 Power parameter for the Minkowski metric When p 1 this
is equivalent to using manhattandistance l1 and euclideandistance l2 for p 2 For
arbitrary p minkowskidistance lp is used
metric string or callable default ‘minkowski’ the distance metric to use for the tree The
default metric is minkowski and with p2 is equivalent to the standard Euclidean metric
See the documentation of the DistanceMetric class for a list of available metrics
metricparams dict optional default None Additional keyword arguments for the metric
function
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details Doesn’t affect fit method
See also
RadiusNeighborsClassifier
KNeighborsRegressor
RadiusNeighborsRegressor
NearestNeighbors
Notes
See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and
leafsize
Warning Regarding the Nearest Neighbors algorithms if it is found that two neighbors neighbor k1 and
k have identical distances but different labels the results will depend on the ordering of the training data
httpsenwikipediaorgwikiKnearestneighboralgorithm

values
getparams self deep Get parameters for this estimator
kneighbors self X nneighbors Finds the Kneighbors of a point
kneighborsgraph self X nneighbors mode Computes the weighted graph of kNeighbors for
points in X
predict self X Predict the class labels for the provided data
predictproba self X Return probability estimates for the test data X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfnneighbors5 weights’uniform’ algorithm’auto’ leafsize30 p2met
ric’minkowski’ metricparamsNone njobsNone kwargs
fitselfXy
Fit the model using X as training data and y as target values
Parameters
Xarraylike sparse matrix BallTree KDTree Training data If array or matrix shape
nsamples nfeatures or nsamples nsamples if metric’precomputed’
yarraylike sparse matrix Target values of shape nsamples or nsamples
noutputs
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
kneighbors selfXNone nneighborsNone returndistanceTrue
Finds the Kneighbors of a point Returns indices of and distances to the neighbors of each point
Parameters

Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors to get default is the value passed to the construc
tor
returndistance boolean optional Defaults to True If False distances will not be re
turned
Returns
dist array Array representing the lengths to points only present if returndistanceTrue
ind array Indices of the nearest points in the population matrix
Examples
In the following example we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to 111
samples 0 0 0 0 5 0 1 1 5
 from sklearnneighbors import NearestNeighbors
neigh NearestNeighborsnneighbors1
neighfitsamples
NearestNeighborsalgorithmauto leafsize30
printneighkneighbors1 1 1
array05 array2
As you can see it returns 05 and 2 which means that the element is at distance 05 and is the third
element of samples indexes start at 0 You can also query for multiple points
X 0 1 0 1 0 1
neighkneighborsX returndistance False
array1
2
kneighborsgraph selfXNone nneighborsNone mode’connectivity’
Computes the weighted graph of kNeighbors for points in X
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors for each sample default is value passed to the
constructor
mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamplesfit nsamplesfit is the
number of samples in the fitted data Ai j is assigned the weight of edge that connects i
to j

A  neighkneighborsgraphX
Atoarray
array1 0 1
0 1 1
1 0 1
```
predictselfX
Predict the class labels for the provided data
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric 'precom
puted' Test samples
Returns
yarray of shape nsamples or nsamples noutputs Class labels for each data sample
predictproba selfX
Return probability estimates for the test data X
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric 'precom
puted' Test samples
Returns
parray of shape nsamples nclasses or a list of noutputs of such arrays if noutputs
 1 The class probabilities of the input samples Classes are ordered by lexicographic
order
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator

The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
tofit method

Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default 30 Leaf size passed to BallTree or KDTree This can affect
the speed of the construction and query as well as the memory required to store the tree
The optimal value depends on the nature of the problem
pinteger optional default 2 Power parameter for the Minkowski metric When p 1 this
is equivalent to using manhattandistance l1 and euclideandistance l2 for p 2 For
arbitrary p minkowskidistance lp is used
metric string or callable default ‘minkowski’ the distance metric to use for the tree The
default metric is minkowski and with p2 is equivalent to the standard Euclidean metric
See the documentation of the DistanceMetric class for a list of available metrics
metricparams dict optional default None Additional keyword arguments for the metric
function
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details Doesn’t affect fit method

values
getparams self deep Get parameters for this estimator
kneighbors self X nneighbors Finds the Kneighbors of a point
kneighborsgraph self X nneighbors mode Computes the weighted graph of kNeighbors for
points in X
predict self X Predict the target for the provided data
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfnneighbors5 weights'uniform' algorithm'auto' leafsize30 p2met
ric'minkowski' metricparamsNone njobsNone kwargs
fitselfXy
Fit the model using X as training data and y as target values
Parameters
Xarraylike sparse matrix BallTree KDTree Training data If array or matrix shape
nsamples nfeatures or nsamples nsamples if metric'precomputed'
yarraylike sparse matrix
Target values array of float values shape nsamples or nsamples noutputs
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
kneighbors selfXNone nneighborsNone returndistanceTrue
Finds the Kneighbors of a point Returns indices of and distances to the neighbors of each point
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric 'precom
puted' The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors to get default is the value passed to the construc
tor
returndistance boolean optional Defaults to True If False distances will not be re
turned
Returns
dist array Array representing the lengths to points only present if returndistanceTrue
ind array Indices of the nearest points in the population matrix

Examples
In the following example we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to 111
samples 0 0 0 0 5 0 1 1 5
 from sklearnneighbors import NearestNeighbors
neigh NearestNeighborsnneighbors1
neighfitsamples
NearestNeighborsalgorithmauto leafsize30
printneighkneighbors1 1 1
array05 array2
As you can see it returns 05 and 2 which means that the element is at distance 05 and is the third
element of samples indexes start at 0 You can also query for multiple points
X 0 1 0 1 0 1
neighkneighborsX returndistance False
array1
2
kneighborsgraph selfXNone nneighborsNone mode’connectivity’
Computes the weighted graph of kNeighbors for points in X
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors for each sample default is value passed to the
constructor
mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamplesfit nsamplesfit is the
number of samples in the fitted data Ai j is assigned the weight of edge that connects i
to j

NearestNeighborsradiusneighborsgraph
Examples
X 0 3 1
 from sklearnneighbors import NearestNeighbors
neigh NearestNeighborsnneighbors2
neighfitX
NearestNeighborsalgorithmauto leafsize30
A neighkneighborsgraphX
Atoarray
array1 0 1

0 1 1
1 0 1
predictselfX
Predict the target for the provided data
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ Test samples
Returns
yarray of int shape nsamples or nsamples noutputs Target values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnneighborsKNeighborsRegressor
•Face completion with a multioutput estimators

•Imputing missing values with variants of IterativeImputer
•Nearest Neighbors regression
6307sklearnneighbors LocalOutlierFactor
classsklearnneighbors LocalOutlierFactor nneighbors20 algorithm'auto'
leafsize30 metric'minkowski' p2met
ricparamsNone contamination'legacy'
noveltyFalse njobsNone
Unsupervised Outlier Detection using Local Outlier Factor LOF
The anomaly score of each sample is called Local Outlier Factor It measures the local deviation of density of a given sample with respect to its neighbors It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood More precisely locality is given by knearest neighbors whose distance is used to estimate the local density By comparing the local density of a sample to the local densities of its neighbors one can identify samples that have a substantially lower density than their neighbors These are considered outliers
Parameters
nneighbors int optional default20 Number of neighbors to use by default for kneighbors queries If nneighbors is larger than the number of samples provided all samples will be used
algorithm 'auto' 'balltree' 'kdtree' 'brute' optional Algorithm used to compute the nearest neighbors
• 'balltree' will use BallTree
• 'kdtree' will use KDTree
• 'brute' will use a bruteforce search
• 'auto' will attempt to decide the most appropriate algorithm based on the values passed tofit method
Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default30 Leaf size passed to BallTree orKDTree This can affect the speed of the construction and query as well as the memory required to store the tree The optimal value depends on the nature of the problem
metric string or callable default 'minkowski' metric used for the distance computation Any metric from scikitlearn or scipyspatialdistance can be used
If 'precomputed' the training input X is expected to be a distance matrix
If metric is a callable function it is called on each pair of instances rows and the resulting value recorded The callable should take two arrays as input and return one value indicating the distance between them This works for Scipy's metrics but is less efficient than passing the metric name as a string
Valid values for metric are
• from scikitlearn 'cityblock' 'cosine' 'euclidean' 'l1' 'l2' 'manhattan'
• from scipyspatialdistance 'braycurtis' 'canberra' 'chebyshev' 'correlation' 'dice' 'hamming' 'jaccard' 'kulsinski' 'mahalanobis' 'minkowski' 'rogerstanimoto' 'rus sellrao' 'seuclidean' 'sokalmichener' 'sokalsneath' 'sqeuclidean' 'yule'

See the documentation for scipyspatialdistance for details on these metrics httpsdocs scipyorgdocscipyreferencespatialdistancehtml
pinteger optional default2 Parameter for the Minkowski metric from sklearn metricspairwisepairwisedistances When p 1 this is equivalent to using manhattandistance l1 and euclideandistance l2 for p 2 For arbitrary p minkowskidistance lp is used
metricparams dict optional defaultNone Additional keyword arguments for the metric function
contamination float in 0 05 optional default01 The amount of contamination of the data set ie the proportion of outliers in the data set When fitting this is used to define the threshold on the decision function If “auto” the decision function threshold is determined as in the original paper
Changed in version 020 The default value of contamination will change from 01 in 020 toauto in 022
novelty boolean default False By default LocalOutlierFactor is only meant to be used for outlier detection noveltyFalse Set novelty to True if you want to use LocalOutlierFactor for novelty detection In this case be aware that that you should only use predict deci sionfunction and scoresamples on new unseen data and not on the training set
njobs int or None optional defaultNone The number of parallel jobs to run for neigh bors search None means 1 unless in a joblibparallelbackend context1 means using all processors See Glossary for more details Affects only kneighbors and kneighborsgraph methods
Attributes
negativeoutlierfactor numpy array shape nsamples The opposite LOF of the train ing samples The higher the more normal Inliers tend to have a LOF score close to 1 negativeoutlierfactor close to 1 while outliers tend to have a larger LOF score
The local outlier factor LOF of a sample captures its supposed ‘degree of abnormality’ It is the average of the ratio of the local reachability density of a sample and those of its knearest neighbors
nneighbors integer The actual number of neighbors used for kneighbors queries
offset float Offset used to obtain binary labels from the raw scores Observations having a negativeoutlierfactor smaller than offset are detected as abnormal The offset is set to 15 inliers score around 1 except when a contamination parameter different than “auto” is provided In that case the offset is defined in such a way we obtain the expected number of outliers in training

decisionfunction
Shifted opposite of the Local Outlier Factor of X
Bigger is better ie large values correspond to inliers
The shift offset allows a zero threshold for being an outlier Only available for novelty detection when novelty is set to True The argument X is supposed to contain new data if X contains a point from training it considers the later in its own neighborhood Also the samples in X are not considered in the neighborhood of any point
Parameters
Xarraylike shape nsamples nfeatures The query sample or samples to compute the Local Outlier Factor wrt the training samples
Returns
shiftedoppositelofscores array shape nsamples The shifted opposite of the Local Outlier Factor of each input samples The lower the more abnormal Negative scores represent outliers positive scores represent inliers
fitselfXyNone
Fit the model using X as training data
Parameters
Xarraylike sparse matrix BallTree KDTree Training data If array or matrix shape nsamples nfeatures or nsamples nsamples if metric’precomputed’
yIgnored not used present for API consistency by convention
Returns
self object
fitpredict
“Fits the model to the training set X and returns the labels
Label is 1 for an inlier and 1 for an outlier according to the LOF score and the contamination parameter
Parameters
Xarraylike shape nsamples nfeatures defaultNone The query sample or samples to compute the Local Outlier Factor wrt to the training samples
yIgnored not used present for API consistency by convention
Returns
isinlier array shape nsamples Returns 1 for anomaliesoutliers and 1 for inliers
getparams selfdeepTrue

predict
Predict the labels 1 inlier 1 outlier of X according to LOF
This method allows to generalize prediction to new observations not in the training set Only available
for novelty detection when novelty is set to True
Parameters
Xarraylike shape nsamples nfeatures The query sample or samples to compute the
Local Outlier Factor wrt to the training samples
Returns
isinlier array shape nsamples Returns 1 for anomaliesoutliers and 1 for inliers
scoresamples
Opposite of the Local Outlier Factor of X
It is the opposite as bigger is better ie large values correspond to inliers
Only available for novelty detection when novelty is set to True The argument X is supposed to contain
new data if X contains a point from training it considers the later in its own neighborhood Also the
samples in X are not considered in the neighborhood of any point The scoresamples on training data is
available by considering the the negativeoutlierfactor attribute
Parameters
Xarraylike shape nsamples nfeatures The query sample or samples to compute the
Local Outlier Factor wrt the training samples
Returns
oppositelofscores array shape nsamples The opposite of the Local Outlier Factor of
each input samples The lower the more abnormal

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnneighborsLocalOutlierFactor
•Comparing anomaly detection algorithms for outlier detection on toy datasets
•Outlier detection with Local Outlier Factor LOF
•Novelty detection with Local Outlier Factor LOF

metricparamsNone njobsNone
kwargs
Classifier implementing a vote among neighbors within a given radius
Read more in the User Guide
Parameters
radius float optional default 10 Range of parameter space to use by default for
radiusneighbors queries
weights str or callable weight function used in prediction Possible values
• ‘uniform’ uniform weights All points in each neighborhood are weighted equally
• ‘distance’ weight points by the inverse of their distance in this case closer neighbors
of a query point will have a greater influence than neighbors which are further away
• callable a userdefined function which accepts an array of distances and returns an
array of the same shape containing the weights
Uniform weights are used by default
algorithm ‘auto’ ‘balltree’ ‘kdtree’ ‘brute’ optional Algorithm used to compute the
nearest neighbors
• ‘balltree’ will use BallTree
• ‘kdtree’ will use KDTree
• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
tofit method
Note fitting on sparse input will override the setting of this parameter using brute force

scikitlearn user guide Release 0213
leafsize int optional default 30 Leaf size passed to BallTree or KDTree This can affect
the speed of the construction and query as well as the memory required to store the tree
The optimal value depends on the nature of the problem
pinteger optional default 2 Power parameter for the Minkowski metric When p 1 this
is equivalent to using manhattandistance l1 and euclideandistance l2 for p 2 For
arbitrary p minkowskidistance lp is used
metric string or callable default ‘minkowski’ the distance metric to use for the tree The
default metric is minkowski and with p2 is equivalent to the standard Euclidean metric
See the documentation of the DistanceMetric class for a list of available metrics
outlierlabel int optional default None Label which is given for outlier samples samples
with no neighbors on given radius If set to None ValueError is raised when outlier is
detected
metricparams dict optional default None Additional keyword arguments for the metric
function
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means

radiusneighbors self X radius Finds the neighbors within a given radius of a point or
points
radiusneighborsgraph self X radius
modeComputes the weighted graph of Neighbors for points
in X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfradius10 weights'uniform' algorithm'auto' leafsize30 p2met
ric'minkowski' outlierlabelNone metricparamsNone njobsNone kwargs
fitselfXy
Fit the model using X as training data and y as target values
Parameters
Xarraylike sparse matrix BallTree KDTree Training data If array or matrix shape
nsamples nfeatures or nsamples nsamples if metric'precomputed'
yarraylike sparse matrix Target values of shape nsamples or nsamples
noutputs
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict the class labels for the provided data
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric 'precom
puted' Test samples
Returns
yarray of shape nsamples or nsamples noutputs Class labels for each data sample
radiusneighbors selfXNone radiusNone returndistanceTrue
Finds the neighbors within a given radius of a point or points
Return the indices and distances of each point from the dataset lying in a ball with size radius around
the points of the query array Points lying on the boundary are included in the results
The result points are notnecessarily sorted by distance to their query point
Parameters

Xarraylike nsamples nfeatures optional The query point or points If not provided
neighbors of each indexed point are returned In this case the query point is not considered
its own neighbor
radius float Limiting distance of neighbors to return default is the value passed to the
constructor
returndistance boolean optional Defaults to True If False distances will not be re
turned
Returns
dist array shape nsamples of arrays Array representing the distances to each point
only present if returndistanceTrue The distance values are computed according to the
metric constructor parameter
ind array shape nsamples of arrays An array of arrays of indices of the approximate
nearest points from the population matrix that lie within a ball of size radius around the
query points
Notes
Because the number of neighbors of each point is not necessarily equal the results for multiple query
points cannot be fit in a standard data array For efficiency radiusneighbors returns arrays of
objects where each object is a 1D array of indices or distances
Examples
In the following example we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to 1 1 1
```
 import numpy as np
samples  0 0 0 0 5 0 1 1 5
 from sklearnneighbors import NearestNeighbors
neigh  NearestNeighborsradius16
neighfitsamples
NearestNeighborsalgorithmauto leafsize30
rng  neighradiusneighbors1 1 1
printnpasarrayrng00
15 05
printnpasarrayrng10
1 2
```
The first array returned contains the distances to all points which are closer than 16 while the second
array returned contains their indices In general multiple points can be queried at the same time
radiusneighborsgraph selfXNone radiusNone mode’connectivity’
Computes the weighted graph of Neighbors for points in X
Neighborhoods are restricted the points at a distance lower than radius
Parameters
Xarraylike shape nsamples nfeatures optional The query point or points If not
provided neighbors of each indexed point are returned In this case the query point is not
considered its own neighbor
radius float Radius of neighborhoods default is the value passed to the constructor

mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamples Ai j is assigned the
weight of edge that connects i to j

```
The first array returned contains the distances to all points which are closer than 16 while the second
array returned contains their indices In general multiple points can be queried at the same time
radiusneighborsgraph selfXNone radiusNone mode’connectivity’
Computes the weighted graph of Neighbors for points in X
Neighborhoods are restricted the points at a distance lower than radius
Parameters
Xarraylike shape nsamples nfeatures optional The query point or points If not
provided neighbors of each indexed point are returned In this case the query point is not
considered its own neighbor
radius float Radius of neighborhoods default is the value passed to the constructor
mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamples Ai j is assigned the
weight of edge that connects i to j

kneighborsgraph
Examples
```
X  0 3 1
 from sklearnneighbors import NearestNeighbors
neigh  NearestNeighborsradius15
neighfitX
NearestNeighborsalgorithmauto leafsize30
A  neighradiusneighborsgraphX
Atoarray
array1 0 1
0 1 0
1 0 1
```

scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
63010sklearnneighbors NearestCentroid
classsklearnneighbors NearestCentroid metric’euclidean’ shrinkthresholdNone
Nearest centroid classifier
Each class is represented by its centroid with test samples classified to the class with the nearest centroid
Read more in the User Guide
Parameters
metric string or callable The metric to use when calculating distance between instances in
a feature array If metric is a string or callable it must be one of the options allowed by
metricspairwisepairwisedistances for its metric parameter The centroids for the samples
corresponding to each class is the point from which the sum of the distances according to
the metric of all samples that belong to that particular class are minimized If the “manhat
tan” metric is provided this centroid is the median and for all other metrics the centroid is
now set to be the mean

shrinkthreshold float optional default None Threshold for shrinking centroids to re
move features
Attributes
centroids arraylike shape nclasses nfeatures Centroid of each class
See also
sklearnneighborsKNeighborsClassifier nearest neighbors classifier
Notes
When used for text classification with tfidf vectors this classifier is also known as the Rocchio classifier
References
Tibshirani R Hastie T Narasimhan B Chu G 2002 Diagnosis of multiple cancer types by shrunken
centroids of gene expression Proceedings of the National Academy of Sciences of the United States of America

clffitX y
NearestCentroidmetriceuclidean shrinkthresholdNone
printclfpredict08 1
1
Methods
fitself X y Fit the NearestCentroid model according to the given
training data
getparams self deep Get parameters for this estimator
predict self X Perform classification on an array of test vectors X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfmetric’euclidean’ shrinkthresholdNone
fitselfXy
Fit the NearestCentroid model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples is the number of samples and nfeatures is the number of features Note that

centroid shrinking cannot be used with sparse matrices
yarray shape nsamples Target values integers
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Perform classification on an array of test vectors X
The predicted class C for each sample in X is returned
Parameters
Xarraylike shape nsamples nfeatures
Returns
Carray shape nsamples
Notes
If the metric constructor parameter is “precomputed” X is assumed to be the distance matrix between the
data to be predicted and selfcentroids
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Examples using sklearnneighborsNearestCentroid
•Nearest Centroid Classification
•Classification of text documents using sparse features
63011sklearnneighbors NearestNeighbors
classsklearnneighbors NearestNeighbors nneighbors5 radius10 algorithm’auto’
leafsize30 metric’minkowski’ p2met
ricparamsNone njobsNone kwargs
Unsupervised learner for implementing neighbor searches
Read more in the User Guide
Parameters
nneighbors int optional default 5 Number of neighbors to use by default for
kneighbors queries
radius float optional default 10 Range of parameter space to use by default for
radiusneighbors queries
algorithm ‘auto’ ‘balltree’ ‘kdtree’ ‘brute’ optional Algorithm used to compute the
nearest neighbors
• ‘balltree’ will use BallTree
• ‘kdtree’ will use KDTree
• ‘brute’ will use a bruteforce search
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
tofit method
Note fitting on sparse input will override the setting of this parameter using brute force
leafsize int optional default 30 Leaf size passed to BallTree or KDTree This can affect
the speed of the construction and query as well as the memory required to store the tree
The optimal value depends on the nature of the problem
metric string or callable default ‘minkowski’ metric to use for distance computation Any
metric from scikitlearn or scipyspatialdistance can be used
If metric is a callable function it is called on each pair of instances rows and the resulting
value recorded The callable should take two arrays as input and return one value indicating
the distance between them This works for Scipy’s metrics but is less efficient than passing
the metric name as a string
Distance matrices are not supported
Valid values for metric are
• from scikitlearn ‘cityblock’ ‘cosine’ ‘euclidean’ ‘l1’ ‘l2’ ‘manhattan’
• from scipyspatialdistance ‘braycurtis’ ‘canberra’ ‘chebyshev’ ‘correlation’ ‘dice’
‘hamming’ ‘jaccard’ ‘kulsinski’ ‘mahalanobis’ ‘minkowski’ ‘rogerstanimoto’ ‘rus
sellrao’ ‘seuclidean’ ‘sokalmichener’ ‘sokalsneath’ ‘sqeuclidean’ ‘yule’
See the documentation for scipyspatialdistance for details on these metrics

pinteger optional default 2 Parameter for the Minkowski metric from
sklearnmetricspairwisepairwisedistances When p 1 this is equivalent to us
ing manhattandistance l1 and euclideandistance l2 for p 2 For arbitrary p
minkowskidistance lp is used
metricparams dict optional default None Additional keyword arguments for the metric
function
njobs int or None optional defaultNone The number of parallel jobs to run for neighbors
searchNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details

Parameters
Xarraylike sparse matrix BallTree KDTree Training data If array or matrix shape
nsamples nfeatures or nsamples nsamples if metric’precomputed’
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
kneighbors selfXNone nneighborsNone returndistanceTrue
Finds the Kneighbors of a point Returns indices of and distances to the neighbors of each point
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors to get default is the value passed to the construc
tor
returndistance boolean optional Defaults to True If False distances will not be re
turned
Returns
dist array Array representing the lengths to points only present if returndistanceTrue
ind array Indices of the nearest points in the population matrix
Examples
In the following example we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to 111

scikitlearn user guide Release 0213
samples 0 0 0 0 5 0 1 1 5
 from sklearnneighbors import NearestNeighbors
neigh NearestNeighborsnneighbors1
neighfitsamples
NearestNeighborsalgorithmauto leafsize30
printneighkneighbors1 1 1
array05 array2
As you can see it returns 05 and 2 which means that the element is at distance 05 and is the third
element of samples indexes start at 0 You can also query for multiple points
X 0 1 0 1 0 1
neighkneighborsX returndistance False
array1
2
kneighborsgraph selfXNone nneighborsNone mode’connectivity’
Computes the weighted graph of kNeighbors for points in X
Parameters
Xarraylike shape nquery nfeatures or nquery nindexed if metric ‘precom
puted’ The query point or points If not provided neighbors of each indexed point are
returned In this case the query point is not considered its own neighbor
nneighbors int Number of neighbors for each sample default is value passed to the
constructor
mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamplesfit nsamplesfit is the
number of samples in the fitted data Ai j is assigned the weight of edge that connects i
to j
See also
NearestNeighborsradiusneighborsgraph
Examples
X 0 3 1
 from sklearnneighbors import NearestNeighbors
neigh NearestNeighborsnneighbors2
neighfitX
NearestNeighborsalgorithmauto leafsize30
A neighkneighborsgraphX
Atoarray
array1 0 1
0 1 1
1 0 1
radiusneighbors selfXNone radiusNone returndistanceTrue
Finds the neighbors within a given radius of a point or points

Return the indices and distances of each point from the dataset lying in a ball with size radius around
the points of the query array Points lying on the boundary are included in the results
The result points are notnecessarily sorted by distance to their query point
Parameters
Xarraylike nsamples nfeatures optional The query point or points If not provided
neighbors of each indexed point are returned In this case the query point is not considered
its own neighbor
radius float Limiting distance of neighbors to return default is the value passed to the
constructor
returndistance boolean optional Defaults to True If False distances will not be re
turned
Returns
dist array shape nsamples of arrays Array representing the distances to each point
only present if returndistanceTrue The distance values are computed according to the
metric constructor parameter
ind array shape nsamples of arrays An array of arrays of indices of the approximate
nearest points from the population matrix that lie within a ball of size radius around the
query points
Notes
Because the number of neighbors of each point is not necessarily equal the results for multiple query
points cannot be fit in a standard data array For efficiency radiusneighbors returns arrays of
objects where each object is a 1D array of indices or distances
Examples
In the following example we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to 1 1 1
```
 import numpy as np
samples  0 0 0 0 5 0 1 1 5
 from sklearnneighbors import NearestNeighbors
neigh  NearestNeighborsradius16
neighfitsamples
NearestNeighborsalgorithmauto leafsize30
rng  neighradiusneighbors1 1 1
printnpasarrayrng00
15 05
printnpasarrayrng10
1 2
```
The first array returned contains the distances to all points which are closer than 16 while the second
array returned contains their indices In general multiple points can be queried at the same time
radiusneighborsgraph selfXNone radiusNone mode’connectivity’
Computes the weighted graph of Neighbors for points in X
Neighborhoods are restricted the points at a distance lower than radius
Parameters

Xarraylike shape nsamples nfeatures optional The query point or points If not
provided neighbors of each indexed point are returned In this case the query point is not
considered its own neighbor
radius float Radius of neighborhoods default is the value passed to the constructor
mode ‘connectivity’ ‘distance’ optional Type of returned matrix ‘connectivity’ will
return the connectivity matrix with ones and zeros in ‘distance’ the edges are Euclidean
distance between points
Returns
Asparse matrix in CSR format shape nsamples nsamples Ai j is assigned the
weight of edge that connects i to j

maxiter50 tol1e05
callbackNone verbose0
randomstateNone
Neighborhood Components Analysis
Neighborhood Component Analysis NCA is a machine learning algorithm for metric learning It learns a linear
transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors
rule in the transformed space
Read more in the User Guide
630sklearnneighbors Nearest Neighbors 2199

Parameters
ncomponents int optional defaultNone Preferred dimensionality of the projected space
If None it will be set to nfeatures
init string or numpy array optional default'auto' Initialization of the linear transformation
Possible options are 'auto' 'pca' 'lda' 'identity' 'random' and a numpy array of shape
nfeaturesa nfeaturesb
'auto' Depending on ncomponents the most reasonable initialization will be chosen
Ifncomponents nclasses we use 'lda' as it uses labels information If
not butncomponents minnfeatures nsamples we use 'pca' as it
projects data in meaningful directions those of higher variance Otherwise we just use
'identity'
'pca'ncomponents principal components of the inputs passed to fit will be used to
initialize the transformation See decompositionPCA
'lda'minncomponents nclasses most discriminative components of the
inputs passed to fit will be used to initialize the transformation If
ncomponents nclasses the rest of the components will be zero See
discriminantanalysisLinearDiscriminantAnalysis
'identity' Ifncomponents is strictly smaller than the dimensionality of the inputs
passed tofit the identity matrix will be truncated to the first ncomponents rows
'random' The initial transformation will be a random array of shape ncomponents
nfeatures Each value is sampled from the standard normal distribution
numpy array nfeaturesb must match the dimensionality of the inputs passed to fit
and nfeaturesa must be less than or equal to that If ncomponents is not None
nfeaturesa must match it
warmstart bool optional defaultFalse If True and fit has been called before the solu
tion of the previous call to fit is used as the initial linear transformation ncomponents
andinit will be ignored
maxiter int optional default50 Maximum number of iterations in the optimization
tolfloat optional default1e5 Convergence tolerance for the optimization
callback callable optional defaultNone If not None this function is called after every
iteration of the optimizer taking as arguments the current solution flattened transformation
matrix and the number of iterations This might be useful in case one wants to examine or
store the transformation found after each iteration
verbose int optional default0 If 0 no progress messages will be printed If 1 progress
messages will be printed to stdout If 1 progress messages will be printed and the disp
parameter of scipyoptimizeminimize will be set to verbose 2
randomstate int or numpyRandomState or None optional defaultNone A pseudo ran
dom number generator object or a seed for it if int If initrandom randomstate
is used to initialize the random transformation If initpca randomstate is
passed as an argument to PCA when initializing the transformation
Attributes
components array shape ncomponents nfeatures The linear transformation learned dur
ing fitting
niter int Counts the number of iterations performed by the optimizer

Bernoulli Restricted Boltzmann Machine RBM
A Restricted Boltzmann Machine with binary visible units and binary hidden units Parameters are estimated
using Stochastic Maximum Likelihood SML also known as Persistent Contrastive Divergence PCD 2
The time complexity of this implementation is Od2assuming d nfeatures ncomponents
Read more in the User Guide
Parameters
ncomponents int optional Number of binary hidden units
learningrate float optional The learning rate for weight updates It is highly recommended
to tune this hyperparameter Reasonable values are in the 100 3 range
batchsize int optional Number of examples per minibatch
niter int optional Number of iterationssweeps over the training dataset to perform during
training
verbose int optional The verbosity level The default zero means silent mode
randomstate integer or RandomState optional A random number generator instance to de
fine the state of the random permutations generator If an integer is given it fixes the seed
Defaults to the global numpy random number generator
Attributes

interceptthidden arraylike shape ncomponents Biases of the hidden units
interceptvisible arraylike shape nfeatures Biases of the visible units
components arraylike shape ncomponents nfeatures Weight matrix where nfeatures
in the number of visible units and ncomponents is the number of hidden units

earlystoppingFalse validationfraction01
beta109 beta20999 epsilon1e08
niternochange10
Multilayer Perceptron classifier
This model optimizes the logloss function using LBFGS or stochastic gradient descent
New in version 018
Parameters
hiddenlayersizes tuple length nlayers 2 default 100 The ith element represents the
number of neurons in the ith hidden layer
activation ‘identity’ ‘logistic’ ‘tanh’ ‘relu’ default ‘relu’ Activation function for the hid
den layer
• ‘identity’ noop activation useful to implement linear bottleneck returns fx x
• ‘logistic’ the logistic sigmoid function returns fx 1 1 expx
• ‘tanh’ the hyperbolic tan function returns fx tanhx
• ‘relu’ the rectified linear unit function returns fx max0 x
solver ‘lbfgs’ ‘sgd’ ‘adam’ default ‘adam’ The solver for weight optimization

• ‘lbfgs’ is an optimizer in the family of quasiNewton methods
• ‘sgd’ refers to stochastic gradient descent
• ‘adam’ refers to a stochastic gradientbased optimizer proposed by Kingma Diederik and Jimmy Ba
Note The default solver ‘adam’ works pretty well on relatively large datasets with thou sands of training samples or more in terms of both training time and validation score For small datasets however ‘lbfgs’ can converge faster and perform better
alpha float optional default 00001 L2 penalty regularization term parameter
batchsize int optional default ‘auto’ Size of minibatches for stochastic optimizers If the solver is ‘lbfgs’ the classifier will not use minibatch When set to “auto” batchsizemin200 nsamples
learningrate ‘constant’ ‘invscaling’ ‘adaptive’ default ‘constant’ Learning rate schedule for weight updates
• ‘constant’ is a constant learning rate given by ‘learningrateinit’
• ‘invscaling’ gradually decreases the learning rate at each time step ‘t’ using an in verse scaling exponent of ‘powert’ effectivelearningrate learningrateinit powt powert
• ‘adaptive’ keeps the learning rate constant to ‘learningrateinit’ as long as training loss keeps decreasing Each time two consecutive epochs fail to decrease training loss by at least tol or fail to increase validation score by at least tol if ‘earlystopping’ is on the current learning rate is divided by 5
Only used when solversgd
learningrateinit double optional default 0001 The initial learning rate used It controls the stepsize in updating the weights Only used when solver’sgd’ or ‘adam’
powert double optional default 05 The exponent for inverse scaling learning rate It is used in updating effective learning rate when the learningrate is set to ‘invscaling’ Only used when solver’sgd’
maxiter int optional default 200 Maximum number of iterations The solver iterates until convergence determined by ‘tol’ or this number of iterations For stochastic solvers ‘sgd’ ‘adam’ note that this determines the number of epochs how many times each data point will be used not the number of gradient steps
shuffle bool optional default True Whether to shuffle samples in each iteration Only used when solver’sgd’ or ‘adam’
randomstate int RandomState instance or None optional default None If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
tolfloat optional default 1e4 Tolerance for the optimization When the loss or score is not improving by at least tol forniternochange consecutive iterations unless learningrate is set to ‘adaptive’ convergence is considered to be reached and training stops
verbose bool optional default False Whether to print progress messages to stdout
warmstart bool optional default False When set to True reuse the solution of the previous call to fit as initialization otherwise just erase the previous solution See the Glossary

momentum float default 09 Momentum for gradient descent update Should be between 0 and 1 Only used when solver’sgd’
nesterovsmomentum boolean default True Whether to use Nesterov’s momentum Only used when solver’sgd’ and momentum 0
earlystopping bool default False Whether to use early stopping to terminate training when validation score is not improving If set to true it will automatically set aside 10 of training data as validation and terminate training when validation score is not improving by at least tol for niternochange consecutive epochs The split is stratified except in a multilabel setting Only effective when solver’sgd’ or ‘adam’
validationfraction float optional default 01 The proportion of training data to set aside as validation set for early stopping Must be between 0 and 1 Only used if earlystopping is True
beta1 float optional default 09 Exponential decay rate for estimates of first moment vector in adam should be in 0 1 Only used when solver’adam’
beta2 float optional default 0999 Exponential decay rate for estimates of second moment vector in adam should be in 0 1 Only used when solver’adam’
epsilon float optional default 1e8 Value for numerical stability in adam Only used when solver’adam’
niternochange int optional default 10 Maximum number of epochs to not meet tol improvement Only effective when solver’sgd’ or ‘adam’
New in version 020
Attributes
classes array or list of array of shape nclasses Class labels for each output
loss float The current loss computed with the loss function
coefs list length nlayers 1 The ith element in the list represents the weight matrix corre sponding to layer i
intercepts list length nlayers 1 The ith element in the list represents the bias vector cor responding to layer i 1
niter int The number of iterations the solver has ran
nlayers int Number of layers
noutputs int Number of outputs
outactivation string Name of the output activation function
Notes
MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters
It can also have a regularization term added to the loss function that shrinks model parameters to prevent over fitting
This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point values

fitselfXy
Fit the model to data matrix X and targets y
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input data
yarraylike shape nsamples or nsamples noutputs The target values class labels in classification real numbers in regression
Returns
self returns a trained MLP model
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit
Update the model with a single iteration over the given data
631sklearnneuralnetwork Neural network models 2211

Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
yarraylike shape nsamples The target values
classes array shape nclasses default None Classes across all calls to partialfit Can be
obtained via npuniqueyall where yall is the target vector of the entire dataset
This argument is required for the first call to partialfit and can be omitted in the subse
quent calls Note that y doesn’t need to contain all labels in classes
Returns
self returns a trained MLP model
predictselfX
Predict using the multilayer perceptron classifier
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
Returns
yarraylike shape nsamples or nsamples nclasses The predicted classes
predictlogproba selfX
Return the log of probability estimates
Parameters
Xarraylike shape nsamples nfeatures The input data
Returns
logyprob arraylike shape nsamples nclasses The predicted logprobability of the
sample for each class in the model where classes are ordered as they are in self
classes Equivalent to logpredictprobaX
predictproba selfX
Probability estimates
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
Returns
yprob arraylike shape nsamples nclasses The predicted probability of the sample
for each class in the model where classes are ordered as they are in selfclasses
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Multilayer Perceptron regressor
This model optimizes the squaredloss using LBFGS or stochastic gradient descent
New in version 018
Parameters
hiddenlayersizes tuple length nlayers 2 default 100 The ith element represents the
number of neurons in the ith hidden layer
activation ‘identity’ ‘logistic’ ‘tanh’ ‘relu’ default ‘relu’ Activation function for the hid
den layer
• ‘identity’ noop activation useful to implement linear bottleneck returns fx x
• ‘logistic’ the logistic sigmoid function returns fx 1 1 expx
• ‘tanh’ the hyperbolic tan function returns fx tanhx
• ‘relu’ the rectified linear unit function returns fx max0 x
solver ‘lbfgs’ ‘sgd’ ‘adam’ default ‘adam’ The solver for weight optimization
• ‘lbfgs’ is an optimizer in the family of quasiNewton methods
• ‘sgd’ refers to stochastic gradient descent

• ‘adam’ refers to a stochastic gradientbased optimizer proposed by Kingma Diederik and Jimmy Ba
Note The default solver ‘adam’ works pretty well on relatively large datasets with thousands of training samples or more in terms of both training time and validation score For small datasets however ‘lbfgs’ can converge faster and perform better
alpha float optional default 00001 L2 penalty regularization term parameter
batchsize int optional default ‘auto’ Size of minibatches for stochastic optimizers If the solver is ‘lbfgs’ the classifier will not use minibatch When set to “auto” batchsizemin200 nsamples
learningrate ‘constant’ ‘invscaling’ ‘adaptive’ default ‘constant’ Learning rate schedule for weight updates
• ‘constant’ is a constant learning rate given by ‘learningrateinit’
• ‘invscaling’ gradually decreases the learning rate learningrate at each time step ‘t’ using an inverse scaling exponent of ‘powert’ effectivelearningrate learningrateinit powt powert
• ‘adaptive’ keeps the learning rate constant to ‘learningrateinit’ as long as training loss keeps decreasing Each time two consecutive epochs fail to decrease training loss by at least tol or fail to increase validation score by at least tol if ‘earlystopping’ is on the current learning rate is divided by 5
Only used when solver’sgd’
learningrateinit double optional default 0001 The initial learning rate used It controls the stepsize in updating the weights Only used when solver’sgd’ or ‘adam’
powert double optional default 05 The exponent for inverse scaling learning rate It is used in updating effective learning rate when the learningrate is set to ‘invscaling’ Only used when solver’sgd’
maxiter int optional default 200 Maximum number of iterations The solver iterates until convergence determined by ‘tol’ or this number of iterations For stochastic solvers ‘sgd’ ‘adam’ note that this determines the number of epochs how many times each data point will be used not the number of gradient steps
shuffle bool optional default True Whether to shuffle samples in each iteration Only used when solver’sgd’ or ‘adam’
randomstate int RandomState instance or None optional default None If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
tolfloat optional default 1e4 Tolerance for the optimization When the loss or score is not improving by at least tol forniternochange consecutive iterations unless learningrate is set to ‘adaptive’ convergence is considered to be reached and training stops
verbose bool optional default False Whether to print progress messages to stdout
warmstart bool optional default False When set to True reuse the solution of the previous call to fit as initialization otherwise just erase the previous solution See the Glossary
momentum float default 09 Momentum for gradient descent update Should be between 0 and 1 Only used when solver’sgd’

nesterovsmomentum boolean default True Whether to use Nesterov’s momentum Only used when solver’sgd’ and momentum 0
earlystopping bool default False Whether to use early stopping to terminate training when validation score is not improving If set to true it will automatically set aside 10 of training data as validation and terminate training when validation score is not improving by at least tol forniternochange consecutive epochs Only effective when solver’sgd’ or ‘adam’
validationfraction float optional default 01 The proportion of training data to set aside as validation set for early stopping Must be between 0 and 1 Only used if earlystopping is True
beta1 float optional default 09 Exponential decay rate for estimates of first moment vector in adam should be in 0 1 Only used when solver’adam’
beta2 float optional default 0999 Exponential decay rate for estimates of second moment vector in adam should be in 0 1 Only used when solver’adam’
epsilon float optional default 1e8 Value for numerical stability in adam Only used when solver’adam’
niternochange int optional default 10 Maximum number of epochs to not meet tol improvement Only effective when solver’sgd’ or ‘adam’
New in version 020
Attributes
loss float The current loss computed with the loss function
coefs list length nlayers 1 The ith element in the list represents the weight matrix corresponding to layer i
intercepts list length nlayers 1 The ith element in the list represents the bias vector corresponding to layer i 1
niter int The number of iterations the solver has ran
nlayers int Number of layers
noutputs int Number of outputs
outactivation string Name of the output activation function
Notes
MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters
It can also have a regularization term added to the loss function that shrinks model parameters to prevent over fitting
This implementation works with data represented as dense and sparse numpy arrays of floating point values

fitselfXy
Fit the model to data matrix X and targets y
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input data
yarraylike shape nsamples or nsamples noutputs The target values class labels
in classification real numbers in regression
Returns
self returns a trained MLP model
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
partialfit
Update the model with a single iteration over the given data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
yarraylike shape nsamples The target values
Returns
self returns a trained MLP model

predictselfX
Predict using the multilayer perceptron model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data
Returns
yarraylike shape nsamples noutputs The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnneuralnetworkMLPRegressor
•Partial Dependence Plots

632sklearnpipeline Pipeline
Thesklearnpipeline module implements utilities to build a composite estimator as a chain of transforms and estimators
pipelineFeatureUnion transformerlist Concatenates results of multiple transformer objects
pipelinePipeline steps memory verbose Pipeline of transforms with a final estimator
6321sklearnpipeline FeatureUnion
classsklearnpipeline FeatureUnion transformerlist njobsNone transformerweightsNone verboseFalse
Concatenates results of multiple transformer objects
This estimator applies a list of transformer objects in parallel to the input data then concatenates the results This is useful to combine several feature extraction mechanisms into a single transformer
Parameters of the transformers may be set using its name and the parameter name separated by a ‘’ A transformer may be replaced entirely by setting the parameter with its name to another transformer or removed by setting to ‘drop’ or None
Read more in the User Guide
Parameters
transformerlist list of string transformer tuples List of transformer objects to be applied to the data The first half of each tuple is the name of the transformer
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
transformerweights dict optional Multiplicative weights for features per transformer Keys are transformer names values the weights
verbose boolean optionaldefaultFalse If True the time elapsed while fitting each trans former will be printed as it is completed

transform self X Transform X separately by each transformer concate
nate results
init selftransformerlist njobsNone transformerweightsNone verboseFalse
fitselfXyNone
Fit all transformers using X
Parameters
Xiterable or arraylike depending on transformers Input data used to fit transformers
yarraylike shape nsamples optional Targets for supervised learning
Returns
self FeatureUnion This estimator
fittransform selfXyNone fitparams
Fit all transformers transform the data and concatenate results
Parameters
Xiterable or arraylike depending on transformers Input data to be transformed
yarraylike shape nsamples optional Targets for supervised learning
Returns
Xt arraylike or sparse matrix shape nsamples sumncomponents hstack of results
of transformers sumncomponents is the sum of ncomponents output dimension over
transformers
getfeaturenames self
Get feature names from all transformers
Returns
featurenames list of strings Names of the features produced by transform
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfkwargs
Set the parameters of this estimator

Valid parameter keys can be listed with getparams
Returns
self
transform selfX
Transform X separately by each transformer concatenate results
Parameters
Xiterable or arraylike depending on transformers Input data to be transformed
Returns
Xt arraylike or sparse matrix shape nsamples sumncomponents hstack of results
of transformers sumncomponents is the sum of ncomponents output dimension over
transformers
Examples using sklearnpipelineFeatureUnion
•Concatenating multiple feature extraction methods
6322sklearnpipeline Pipeline
classsklearnpipeline Pipeline steps memoryNone verboseFalse
Pipeline of transforms with a final estimator
Sequentially apply a list of transforms and a final estimator Intermediate steps of the pipeline must be ‘trans
forms’ that is they must implement fit and transform methods The final estimator only needs to implement fit
The transformers in the pipeline can be cached using memory argument
The purpose of the pipeline is to assemble several steps that can be crossvalidated together while setting differ
ent parameters For this it enables setting parameters of the various steps using their names and the parameter
name separated by a ‘’ as in the example below A step’s estimator may be replaced entirely by setting the
parameter with its name to another estimator or a transformer removed by setting it to ‘passthrough’ or None
Read more in the User Guide
Parameters
steps list List of name transform tuples implementing fittransform that are chained in the
order in which they are chained with the last object an estimator
memory None str or object with the joblibMemory interface optional Used to cache the fit
ted transformers of the pipeline By default no caching is performed If a string is given
it is the path to the caching directory Enabling caching triggers a clone of the transform
ers before fitting Therefore the transformer instance given to the pipeline cannot be in
spected directly Use the attribute namedsteps orsteps to inspect estimators within
the pipeline Caching the transformers is advantageous when fitting is time consuming
verbose boolean optional If True the time elapsed while fitting each step will be printed as it
is completed
Attributes
namedsteps bunch object a dictionary with attribute access Readonly attribute to access
any step parameter by user given name Keys are step names and values are steps parameters

tor
score self X y sampleweight Apply transforms and score with the final estimator
setparams self kwargs Set the parameters of this estimator
init selfsteps memoryNone verboseFalse
decisionfunction selfX
Apply transforms and decisionfunction of the final estimator
Parameters
Xiterable Data to predict on Must fulfill input requirements of first step of the pipeline
Returns
yscore arraylike shape nsamples nclasses
fitselfXyNone fitparams
Fit the model
Fit all the transforms one after the other and transform the data then fit the transformed data using the final
estimator
Parameters
Xiterable Training data Must fulfill input requirements of first step of the pipeline
yiterable defaultNone Training targets Must fulfill label requirements for all steps of
the pipeline
fitparams dict of string object Parameters passed to the fit method of each step
where each parameter name is prefixed such that parameter pfor stepshas keysp
Returns
self Pipeline This estimator
fitpredict selfXyNone fitparams
Applies fitpredict of last step in pipeline after transforms
Applies fittransforms of a pipeline to the data followed by the fitpredict method of the final estimator in
the pipeline Valid only if the final estimator implements fitpredict
Parameters
Xiterable Training data Must fulfill input requirements of first step of the pipeline
yiterable defaultNone Training targets Must fulfill label requirements for all steps of
the pipeline

fitparams dict of string object Parameters passed to the fit method of each step
where each parameter name is prefixed such that parameter pfor stepshas keysp
Returns
ypred arraylike
fittransform selfXyNone fitparams
Fit the model and transform with the final estimator
Fits all the transforms one after the other and transforms the data then uses fittransform on transformed
data with the final estimator
Parameters
Xiterable Training data Must fulfill input requirements of first step of the pipeline
yiterable defaultNone Training targets Must fulfill label requirements for all steps of
the pipeline
fitparams dict of string object Parameters passed to the fit method of each step
where each parameter name is prefixed such that parameter pfor stepshas keysp
Returns
Xtarraylike shape nsamples ntransformedfeatures Transformed samples
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform
Apply inverse transformations in reverse order
All estimators in the pipeline must support inversetransform
Parameters
Xtarraylike shape nsamples ntransformedfeatures Data samples where
nsamples is the number of samples and nfeatures is the number of features Must
fulfill input requirements of last step of pipeline’s inversetransform method
Returns
Xtarraylike shape nsamples nfeatures
predictselfXpredictparams
Apply transforms to the data and predict with the final estimator
Parameters
Xiterable Data to predict on Must fulfill input requirements of first step of the pipeline
predictparams dict of string object Parameters to the predict called at the end of
all transformations in the pipeline Note that while this may be used to return uncertainties
from some models with returnstd or returncov uncertainties that are generated by the
transformations in the pipeline are not propagated to the final estimator
Returns
632sklearnpipeline Pipeline 2223

ypred arraylike
predictlogproba selfX
Apply transforms and predictlogproba of the final estimator
Parameters
Xiterable Data to predict on Must fulfill input requirements of first step of the pipeline
Returns
yscore arraylike shape nsamples nclasses
predictproba selfX
Apply transforms and predictproba of the final estimator
Parameters
Xiterable Data to predict on Must fulfill input requirements of first step of the pipeline
Returns
yproba arraylike shape nsamples nclasses
scoreselfXyNone sampleweightNone
Apply transforms and score with the final estimator
Parameters
Xiterable Data to predict on Must fulfill input requirements of first step of the pipeline
yiterable defaultNone Targets used for scoring Must fulfill label requirements for all steps of the pipeline
sampleweight arraylike defaultNone If not None this argument is passed as sampleweight keyword argument to the score method of the final estimator
Returns
score float
setparams selfkwargs
Set the parameters of this estimator
Valid parameter keys can be listed with getparams
Returns
self
transform
Apply transforms and transform with the final estimator
This also works where final estimator is None all prior transformations are applied
Parameters
Xiterable Data to transform Must fulfill input requirements of first step of the pipeline
Returns
Xtarraylike shape nsamples ntransformedfeatures

Examples using sklearnpipelinePipeline
•Explicit feature map approximation for RBF kernels
•Feature agglomeration vs univariate selection
•Concatenating multiple feature extraction methods
•Pipelining chaining a PCA and a logistic regression
•Column Transformer with Mixed Types
•Selecting dimensionality reduction with Pipeline and GridSearchCV
•Column Transformer with Heterogeneous Data Sources
•Underfitting vs Overfitting
•Balance model complexity and crossvalidated score
•Sample pipeline for text feature extraction and evaluation
•Comparing Nearest Neighbors with and without Neighborhood Components Analysis
•Restricted Boltzmann Machine features for digit classification
•SVMAnova SVM with univariate feature selection
•Classification of text documents using sparse features
pipelinemakepipeline steps kwargs Construct a Pipeline from the given estimators
pipelinemakeunion transformers kwargs Construct a FeatureUnion from the given transformers
6323sklearnpipeline makepipeline
sklearnpipeline makepipeline steps kwargs
Construct a Pipeline from the given estimators
This is a shorthand for the Pipeline constructor it does not require and does not permit naming the estimators
Instead their names will be set to the lowercase of their types automatically
Parameters
steps list of estimators
memory None str or object with the joblibMemory interface optional Used to cache the fit
ted transformers of the pipeline By default no caching is performed If a string is given
it is the path to the caching directory Enabling caching triggers a clone of the transform
ers before fitting Therefore the transformer instance given to the pipeline cannot be in
spected directly Use the attribute namedsteps orsteps to inspect estimators within
the pipeline Caching the transformers is advantageous when fitting is time consuming
verbose boolean optional If True the time elapsed while fitting each step will be printed as it
is completed
Returns
pPipeline

sklearnpipelinePipeline Class for creating a pipeline of transforms with a final estimator

Examples
```
 from sklearnnaivebayes import GaussianNB
 from sklearnpreprocessing import StandardScaler
makepipelineStandardScaler GaussianNBpriors None

PipelinememoryNone
stepsstandardscaler
StandardScalercopyTrue withmeanTrue withstdTrue
gaussiannb
GaussianNBpriorsNone varsmoothing1e09
verboseFalse
```
Examples using sklearnpipelinemakepipeline
•Feature transformations with ensembles of trees
•Pipeline Anova SVM
•Imputing missing values with variants of IterativeImputer
•Imputing missing values before building an estimator
•Polynomial interpolation
•Robust linear estimator fitting
•Dimensionality Reduction with Neighborhood Components Analysis
•Using FunctionTransformer to select columns
•Importance of Feature Scaling
•Feature discretization
•Clustering text documents using kmeans
6324sklearnpipeline makeunion
sklearnpipeline makeunion transformers kwargs
Construct a FeatureUnion from the given transformers
This is a shorthand for the FeatureUnion constructor it does not require and does not permit naming the transformers Instead they will be given names automatically based on their types It also does not allow weighting
Parameters
transformers list of estimators
njobs int or None optional defaultNone Number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
verbose boolean optionaldefaultFalse If True the time elapsed while fitting each transformer will be printed as it is completed
Returns
fFeatureUnion

See also
sklearnpipelineFeatureUnion Class for concatenating the results of multiple transformer objects
Examples
```
 from sklearndecomposition import PCA TruncatedSVD
 from sklearnpipeline import makeunion
makeunionPCA TruncatedSVD
FeatureUnionnjobsNone
transformerlistpca
PCAcopyTrue iteratedpowerauto
ncomponentsNone randomstateNone
svdsolverauto tol00 whitenFalse
truncatedsvd
TruncatedSVDalgorithmrandomized
ncomponents2 niter5
randomstateNone tol00
transformerweightsNone verboseFalse
```
Examples using sklearnpipelinemakeunion
•Imputing missing values before building an estimator
633sklearninspection inspection
Thesklearninspection module includes tools for model inspection
```
inspectionpartialdependence estimator X
   Partial dependence of features
inspectionplotpartialdependence
   Partial dependence plots
```
6331sklearninspection partialdependence
```
sklearninspection partialdependence estimator Xfeatures responsemethod’auto’
percentiles005  095  gridresolution100
method’auto’
```
Partial dependence of features
Partial dependence of a feature or a set of features corresponds to the average response of an estimator for each possible value of the feature
Read more in the User Guide
Parameters
estimator BaseEstimator A fitted estimator object implementing predict predictproba or decisionfunction Multioutputmulticlass classifiers are not supported
Xarraylike shape nsamples nfeatures Xis used both to generate a grid of values for the features and to compute the averaged predictions when method is ‘brute’

features list or arraylike of int The target features for which the partial dependency should
be computed
responsemethod ‘auto’ ‘predictproba’ or ‘decisionfunction’ optional default‘auto’
Specifies whether to use predictproba ordecisionfunction as the target response For
regressors this parameter is ignored and the response is always the output of predict By
default predictproba is tried first and we revert to decisionfunction if it doesn’t exist If
method is ‘recursion’ the response is always the output of decisionfunction
percentiles tuple of float optional default005 095 The lower and upper percentile used
to create the extreme values for the grid Must be in 0 1
gridresolution int optional default100 The number of equally spaced points on the grid
for each target feature
method str optional default‘auto’ The method used to calculate the averaged predictions
• ‘recursion’ is only supported for objects inheriting from BaseGradientBoosting
but is more efficient in terms of speed With this method Xis only used to build the
grid and the partial dependences are computed using the training data This method does
not account for the init predicor of the boosting process which may lead to incorrect
values see warning below With this method the target response of a classifier is always
the decision function not the predicted probabilities
• ‘brute’ is supported for any estimator but is more computationally intensive
• If ‘auto’ then ‘recursion’ will be used for BaseGradientBoosting estimators with
initNone and ‘brute’ for all other
Returns
averagedpredictions ndarray shape noutputs lenvalues0 lenvalues1 The pre
dictions for all the points in the grid averaged over all samples in X or over the training data
ifmethod is ‘recursion’ noutputs corresponds to the number of classes in a multi
class setting or to the number of tasks for multioutput regression For classical regression
and binary classification noutputs1 nvaluesfeaturej corresponds to the
sizevaluesj
values seq of 1d ndarrays The values with which the grid has been created The generated grid
is a cartesian product of the arrays in values lenvalues lenfeatures
The size of each array valuesj is eithergridresolution or the number of
unique values in X j whichever is smaller
Warning The ‘recursion’ method only works for gradient boosting estimators and unlike the ‘brute’
method it does not account for the init predictor of the boosting process In practice this will produce the
same values as ‘brute’ up to a constant offset in the target response provided that init is a consant estimator
which is the default However as soon as init is not a constant estimator the partial dependence values
are incorrect for ‘recursion’

Read more in the User Guide
Parameters
estimator BaseEstimator A fitted estimator object implementing predict predictproba or
decisionfunction Multioutputmulticlass classifiers are not supported
Xarraylike shape nsamples nfeatures The data to use to build the grid of values on
which the dependence will be evaluated This is usually the training data
features list of int str pair of int pair of str The target features for which to create the
PDPs If featuresi is an int or a string a oneway PDP is created if featuresi is a tuple a
twoway PDP is created Each tuple must be of size 2 if any entry is a string then it must
be infeaturenames
featurenames seq of str shape nfeatures optional Name of each feature fea
turenamesi holds the name of the feature with index i By default the name of the feature
corresponds to their numerical index
target int optional defaultNone
• In a multiclass setting specifies the class for which the PDPs should be computed Note
that for binary classification the positive class index 1 is always used
• In a multioutput setting specifies the task for which the PDPs should be computed
Ignored in binary classification or classical regression settings
responsemethod 'auto' 'predictproba' or 'decisionfunction' optional default'auto'
Specifies whether to use predictproba ordecisionfunction as the target response For
regressors this parameter is ignored and the response is always the output of predict By
633sklearninspection inspection 2229

default predictproba is tried first and we revert to decisionfunction if it doesn’t exist If
method is ‘recursion’ the response is always the output of decisionfunction
ncols int optional default3 The maximum number of columns in the grid plot
gridresolution int optional default100 The number of equally spaced points on the axes
of the plots for each target feature
percentiles tuple of float optional default005 095 The lower and upper percentile used
to create the extreme values for the PDP axes Must be in 0 1
method str optional default’auto’ The method to use to calculate the partial dependence
predictions
• ‘recursion’ is only supported for objects inheriting from BaseGradientBoosting
but is more efficient in terms of speed With this method Xis optional and is only used
to build the grid and the partial dependences are computed using the training data This
method does not account for the init predicor of the boosting process which may lead
to incorrect values see warning below With this method the target response of a classi
fier is always the decision function not the predicted probabilities
• ‘brute’ is supported for any estimator but is more computationally intensive
• If ‘auto’ then ‘recursion’ will be used for BaseGradientBoosting estimators with
initNone and ‘brute’ for all other
Unlike the ‘brute’ method ‘recursion’ does not account for the init predictor of the boost
ing process In practice this still produces the same plots up to a constant offset in the target
response
njobs int optional defaultNone The number of CPUs to use to compute the partial depen
dencesNone means 1 unless in a joblibparallelbackend context1means
using all processors See Glossary for more details
verbose int optional default0 Verbose output during PD computations
figMatplotlib figure object optional defaultNone A figure object onto which the plots will
be drawn after the figure has been cleared By default a new one is created
linekw dict optional Dict with keywords passed to the matplotlibpyplotplot call
For oneway partial dependence plots
contourkw dict optional Dict with keywords passed to the matplotlibpyplotplot
call For twoway partial dependence plots
Warning The ‘recursion’ method only works for gradient boosting estimators and unlike the ‘brute’
method it does not account for the init predictor of the boosting process In practice this will produce the
same values as ‘brute’ up to a constant offset in the target response provided that init is a consant estimator
which is the default However as soon as init is not a constant estimator the partial dependence values
are incorrect for ‘recursion’

634sklearnpreprocessing Preprocessing and Normalization
Thesklearnpreprocessing module includes scaling centering normalization binarization and imputation
methods
User guide See the Preprocessing data section for further details
preprocessingBinarizer threshold copy Binarize data set feature values to 0 or 1 according to a
threshold
preprocessingFunctionTransformer func
   Constructs a transformer from an arbitrary callable
preprocessingKBinsDiscretizer nbins
   Bin continuous data into intervals
preprocessingKernelCenterer Center a kernel matrix
preprocessingLabelBinarizer neglabel
   Binarize labels in a onevsall fashion
preprocessingLabelEncoder Encode labels with value between 0 and nclasses1
preprocessingMultiLabelBinarizer classes
   Transform between iterable of iterables and a multilabel
format
preprocessingMaxAbsScaler copy Scale each feature by its maximum absolute value
preprocessingMinMaxScaler featurerange
copyTransforms features by scaling each feature to a given
range
preprocessingNormalizer norm copy Normalize samples individually to unit norm
preprocessingOneHotEncoder nvalues   Encode categorical integer features as a onehot numeric
array
preprocessingOrdinalEncoder categories
dtypeEncode categorical features as an integer array
preprocessingPolynomialFeatures degree
   Generate polynomial and interaction features
preprocessingPowerTransformer method
   Apply a power transform featurewise to make data more
Gaussianlike
preprocessingQuantileTransformer   Transform features using quantiles information
preprocessingRobustScaler withcentering
   Scale features using statistics that are robust to outliers
preprocessingStandardScaler copy   Standardize features by removing the mean and scaling to
unit variance

6341sklearnpreprocessing Binarizer
classsklearnpreprocessing Binarizer threshold00 copyTrue
Binarize data set feature values to 0 or 1 according to a threshold
Values greater than the threshold map to 1 while values less than or equal to the threshold map to 0 With the default threshold of 0 only positive values map to 1
Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance
It can also be used as a preprocessing step for estimators that consider boolean random variables eg modelled using the Bernoulli distribution in a Bayesian setting
Read more in the User Guide
Parameters
threshold float optional 00 by default Feature values below or equal to this are replaced by 0 above it by 1 Threshold may not be less than 0 for operations on sparse matrices
copy boolean optional default True set to False to perform inplace binarization and avoid a copy if the input is already a numpy array or a scipysparse CSR matrix
See also
binarize Equivalent function without the estimator API
Notes
If the input is a sparse matrix only the nonzero values are subject to update by the Binarizer class
This estimator is stateless besides constructor parameters the fit method does nothing but is useful when used in a pipeline
Examples
from sklearnpreprocessing import Binarizer
X 1 1 2
2 0 0
0 1 1
transformer BinarizerfitX fit does nothing
transformer
BinarizercopyTrue threshold00
transformertransformX
array1 0 1
1 0 0
0 1 0
Methods
fitself X y Do nothing and return the estimator unchanged
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
Continued on next page

Table 6247 – continued from previous page
setparams self params Set the parameters of this estimator
transform self X copy Binarize each element of X
init selfthreshold00 copyTrue
fitselfXyNone
Do nothing and return the estimator unchanged
This method is just there to implement the usual API and hence work in pipelines
Parameters
Xarraylike
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfXcopyNone
Binarize each element of X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The data to binarize element
by element scipysparse matrices should be in CSR format to avoid an unnecessary copy
copy bool Copy the input X or not

6342sklearnpreprocessing FunctionTransformer
classsklearnpreprocessing FunctionTransformer funcNone inversefuncNone val
idateNone acceptsparseFalse
passy'deprecated'
checkinverseTrue kwargsNone
invkwargsNone
Constructs a transformer from an arbitrary callable
A FunctionTransformer forwards its X and optionally y arguments to a userdefined function or function
object and returns the result of this function This is useful for stateless transformations such as taking the log
of frequencies doing custom scaling etc
Note If a lambda is used as the function then the resulting transformer will not be pickleable
New in version 017
Read more in the User Guide
Parameters
func callable optional defaultNone The callable to use for the transformation This will be
passed the same arguments as transform with args and kwargs forwarded If func is None
then func will be the identity function
inversefunc callable optional defaultNone The callable to use for the inverse transforma
tion This will be passed the same arguments as inverse transform with args and kwargs
forwarded If inversefunc is None then inversefunc will be the identity function
validate bool optional defaultTrue Indicate that the input X array should be checked before
callingfunc The possibilities are
• If False there is no input validation
• If True then X will be converted to a 2dimensional NumPy array or sparse matrix If the
conversion is not possible an exception is raised
Deprecated since version 020 validateTrue as default will be replaced by
validateFalse in 022
acceptsparse boolean optional Indicate that func accepts a sparse matrix as input If validate
is False this has no effect Otherwise if acceptsparse is false sparse matrix inputs will
cause an exception to be raised
passy bool optional defaultFalse Indicate that transform should forward the y argument to
the inner callable
Deprecated since version 019
checkinverse bool defaultTrue Whether to check that or func followed by
inversefunc leads to the original inputs It can be used for a sanity check raising
a warning when the condition is not fulfilled
New in version 020
kwargs dict optional Dictionary of additional keyword arguments to pass to func
invkwargs dict optional Dictionary of additional keyword arguments to pass to in
versefunc

Methods
fitself X y Fit transformer by checking X
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
inversetransform self X Transform X using the inverse function
setparams self params Set the parameters of this estimator
transform self X Transform X using the forward function
init self funcNone inversefuncNone validateNone acceptsparseFalse
passy'deprecated' checkinverseTrue kwargsNone invkwargsNone
fitselfXyNone
Fit transformer by checking X
Ifvalidate isTrue Xwill be checked
Parameters
Xarraylike shape nsamples nfeatures Input array
Returns
self
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Transform X using the inverse function
Parameters
Xarraylike shape nsamples nfeatures Input array
Returns
Xout arraylike shape nsamples nfeatures Transformed input

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform X using the forward function
Parameters
Xarraylike shape nsamples nfeatures Input array
Returns
Xout arraylike shape nsamples nfeatures Transformed input
Examples using sklearnpreprocessingFunctionTransformer
•Using FunctionTransformer to select columns
6343sklearnpreprocessing KBinsDiscretizer
classsklearnpreprocessing KBinsDiscretizer nbins5 encode’onehot’ strat
egy’quantile’
Bin continuous data into intervals
Read more in the User Guide
Parameters
nbins int or arraylike shape nfeatures default5 The number of bins to produce
Raises ValueError if nbins 2
encode ‘onehot’ ‘onehotdense’ ‘ordinal’ default’onehot’ Method used to encode the
transformed result
onehot Encode the transformed result with onehot encoding and return a sparse matrix
Ignored features are always stacked to the right
onehotdense Encode the transformed result with onehot encoding and return a dense ar
ray Ignored features are always stacked to the right
ordinal Return the bin identifier encoded as an integer value
strategy ‘uniform’ ‘quantile’ ‘kmeans’ default’quantile’ Strategy used to define the
widths of the bins
uniform All bins in each feature have identical widths
quantile All bins in each feature have the same number of points
kmeans Values in each bin have the same nearest center of a 1D kmeans cluster
Attributes
nbins int array shape nfeatures Number of bins per feature Bins whose width are too
small ie 1e8 are removed with a warning

binedges array of arrays shape nfeatures The edges of each bin Contain arrays of
varying shapes nbins Ignored features will have empty arrays
See also
sklearnpreprocessingBinarizer class used to bin values as 0or1based on a parameter
threshold
Notes
In bin edges for feature i the first and last values are used only for inversetransform During transform
bin edges are extended to
npconcatenatenpinf binedgesi11 npinf
You can combine KBinsDiscretizer withsklearncomposeColumnTransformer if you only
want to preprocess part of the features
KBinsDiscretizer might produce constant features eg when encode onehot and certain bins
do not contain any data These features can be removed with feature selection algorithms eg sklearn
featureselectionVarianceThreshold
Examples
X 2 1 4 1
 1 2 3 05
  0 3 2 05
  1 4 1 2
est KBinsDiscretizernbins3 encodeordinal strategyuniform
estfitX
KBinsDiscretizer
Xt esttransformX
Xt
array 0 0 0 0
 1 1 1 0
 2 2 2 1
 2 2 2 2
Sometimes it may be useful to convert the data back into the original feature space The
inversetransform function converts the binned data into the original feature space Each value will
be equal to the mean of the two bin edges
estbinedges0

inversetransform self Xt Transforms discretized data back to original feature
space
setparams self params Set the parameters of this estimator
transform self X Discretizes the data
init selfnbins5 encode’onehot’ strategy’quantile’
fitselfXyNone
Fits the estimator
Parameters
Xnumeric arraylike shape nsamples nfeatures Data to be discretized
yignored
Returns
self
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfXt
Transforms discretized data back to original feature space
Note that this function does not regenerate the original data due to discretization rounding
Parameters
Xtnumeric arraylike shape nsample nfeatures Transformed data in the binned space
Returns
Xinv numeric arraylike Data in the original feature space

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
transform selfX
Discretizes the data
Parameters
Xnumeric arraylike shape nsamples nfeatures Data to be discretized
Returns
Xtnumeric arraylike or sparse matrix Data in the binned space
Examples using sklearnpreprocessingKBinsDiscretizer
•Using KBinsDiscretizer to discretize continuous features
•Demonstrating the different strategies of KBinsDiscretizer
•Feature discretization
6344sklearnpreprocessing KernelCenterer
classsklearnpreprocessing KernelCenterer
Center a kernel matrix
Let Kx z be a kernel defined by phixT phiz where phi is a function mapping x to a Hilbert space KernelCenterer centers ie normalize to have zero mean the data without explicitly computing phix It is equivalent to centering phix with sklearnpreprocessingStandardScalerwithstdFalse
Read more in the User Guide
Examples

Parameters
Knumpy array of shape nsamples nsamples Kernel matrix
Returns
self returns an instance of self
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfKcopyTrue
Center kernel matrix
Parameters
Knumpy array of shape nsamples1 nsamples2 Kernel matrix
copy boolean optional default True Set to False to perform inplace computation
Returns
Knew numpy array of shape nsamples1 nsamples2
6345sklearnpreprocessing LabelBinarizer
classsklearnpreprocessing LabelBinarizer neglabel0 poslabel1
sparseoutputFalse
Binarize labels in a onevsall fashion
Several regression and binary classification algorithms are available in scikitlearn A simple way to extend these algorithms to the multiclass classification case is to use the socalled onevsall scheme
At learning time this simply consists in learning one regressor or binary classifier per class In doing so one needs to convert multiclass labels to binary labels belong or does not belong to the class LabelBinarizer makes this process easy with the transform method
At prediction time one assigns the class for which the corresponding model gave the greatest confidence LabelBinarizer makes this easy with the inversetransform method
Read more in the User Guide
Parameters
neglabel int default 0 Value with which negative labels must be encoded
poslabel int default 1 Value with which positive labels must be encoded
sparseoutput boolean default False True if the returned array from transform is desired to be in sparse CSR format
Attributes
classes array of shape nclass Holds the label for each class
ytype str Represents the type of the target data as evaluated by utilsmulticlasstypeoftarget Possible type are ‘continuous’ ‘continuousmultioutput’ ‘binary’ ‘multiclass’ ‘multiclassmultioutput’ ‘multilabelindicator’ and ‘unknown’
sparseinput boolean True if the input data to transform is given as a sparse matrix False otherwise
See also

0 1 0
```
Methods
fitself y Fit label binarizer
fittransform self y Fit label binarizer and transform multiclass labels to
binary labels
getparams self deep Get parameters for this estimator
inversetransform self Y threshold Transform binary labels back to multiclass labels
setparams self params Set the parameters of this estimator
transform self y Transform multiclass labels to binary labels
init selfneglabel0 poslabel1 sparseoutputFalse
fitselfy
Fit label binarizer
Parameters
yarray of shape nsamples or nsamples nclasses Target values The 2d matrix
should only contain 0 and 1 represents multilabel classification
Returns

self returns an instance of self
fittransform selfy
Fit label binarizer and transform multiclass labels to binary labels
The output of transform is sometimes referred to as the 1ofK coding scheme
Parameters
yarray or sparse matrix of shape nsamples or nsamples nclasses Target values
The 2d matrix should only contain 0 and 1 represents multilabel classification Sparse
matrix can be CSR CSC COO DOK or LIL
Returns
Yarray or CSR matrix of shape nsamples nclasses Shape will be nsamples 1 for
binary problems
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfYthresholdNone
Transform binary labels back to multiclass labels
Parameters
Ynumpy array or sparse matrix with shape nsamples nclasses Target values All
sparse matrices are converted to CSR before inverse transformation
threshold float or None Threshold used in the binary and multilabel cases
Use 0 when Ycontains the output of decisionfunction classifier Use 05 when Ycon
tains the output of predictproba
If None the threshold is assumed to be half way between neglabel and poslabel
Returns
ynumpy array or CSR matrix of shape nsamples Target values
Notes
In the case when the binary labels are fractional probabilistic inversetransform chooses the class with
the greatest value Typically this allows to use the output of a linear model’s decisionfunction method
directly as the input of inversetransform
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns

self
transform selfy
Transform multiclass labels to binary labels
The output of transform is sometimes referred to by some authors as the 1ofK coding scheme
Parameters
yarray or sparse matrix of shape nsamples or nsamples nclasses Target values
The 2d matrix should only contain 0 and 1 represents multilabel classification Sparse
matrix can be CSR CSC COO DOK or LIL
Returns
Ynumpy array or CSR matrix of shape nsamples nclasses Shape will be nsamples
1 for binary problems
6346sklearnpreprocessing LabelEncoder
classsklearnpreprocessing LabelEncoder
Encode labels with value between 0 and nclasses1

getparams self deep Get parameters for this estimator
inversetransform self y Transform labels back to original encoding
setparams self params Set the parameters of this estimator
transform self y Transform labels to normalized encoding
init selfargs kwargs
Initialize self See helptypeself for accurate signature
fitselfy
Fit label encoder
Parameters
yarraylike of shape nsamples Target values
Returns
self returns an instance of self
fittransform selfy
Fit label encoder and return encoded labels
Parameters
yarraylike of shape nsamples Target values
Returns
yarraylike of shape nsamples
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfy
Transform labels back to original encoding
Parameters
ynumpy array of shape nsamples Target values
Returns
ynumpy array of shape nsamples

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfy
Transform labels to normalized encoding
Parameters
yarraylike of shape nsamples Target values
Returns
yarraylike of shape nsamples
6347sklearnpreprocessing MultiLabelBinarizer
classsklearnpreprocessing MultiLabelBinarizer classesNone sparseoutputFalse
Transform between iterable of iterables and a multilabel format
Although a list of sets or tuples is a very intuitive format for multilabel data it is unwieldy to process This
transformer converts between this intuitive format and the supported multilabel format a samples x classes
binary matrix indicating the presence of a class label
Parameters
classes arraylike of shape nclasses optional Indicates an ordering for the class labels All
entries should be unique cannot contain duplicate classes
sparseoutput boolean default False Set to true if output binary array is desired in CSR
sparse format
Attributes
classes array of labels A copy of the classes parameter where provided or otherwise the
sorted set of classes found when fitting
See also
sklearnpreprocessingOneHotEncoder encode categorical features using a onehot aka oneofK
scheme
Examples
```
 from sklearnpreprocessing import MultiLabelBinarizer
mlb  MultiLabelBinarizer
mlbfittransform1 2 3
array1 1 0
0 0 1
mlbclasses

Methods
fitself y Fit the label sets binarizer storing classes
fittransform self y Fit the label sets binarizer and transform the given label
sets
getparams self deep Get parameters for this estimator
inversetransform self yt Transform the given indicator matrix into label sets
setparams self params Set the parameters of this estimator
transform self y Transform the given label sets
init selfclassesNone sparseoutputFalse
fitselfy
Fit the label sets binarizer storing classes
Parameters
yiterable of iterables A set of labels any orderable and hashable object for each sample
If theclasses parameter is set ywill not be iterated
Returns
self returns this MultiLabelBinarizer instance
fittransform selfy
Fit the label sets binarizer and transform the given label sets
Parameters
yiterable of iterables A set of labels any orderable and hashable object for each sample
If theclasses parameter is set ywill not be iterated
Returns
yindicator array or CSR matrix shape nsamples nclasses A matrix such that
yindicatori j 1 iffclassesj is inyi and 0 otherwise
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfyt
Transform the given indicator matrix into label sets
Parameters

ytarray or sparse matrix of shape nsamples nclasses A matrix containing only 1s ands
0s
Returns
ylist of tuples The set of labels for each sample such that yi consists of
classesj for eachyti j 1
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfy
Transform the given label sets
Parameters
yiterable of iterables A set of labels any orderable and hashable object for each sample
If theclasses parameter is set ywill not be iterated
Returns
yindicator array or CSR matrix shape nsamples nclasses A matrix such that
yindicatori j 1 iffclassesj is inyi and 0 otherwise
6348sklearnpreprocessing MaxAbsScaler
classsklearnpreprocessing MaxAbsScaler copyTrue
Scale each feature by its maximum absolute value
This estimator scales and translates each feature individually such that the maximal absolute value of each
feature in the training set will be 10 It does not shiftcenter the data and thus does not destroy any sparsity
This scaler can also be applied to sparse CSR or CSC matrices
New in version 017
Parameters
copy boolean optional default is True Set to False to perform inplace scaling and avoid a
copy if the input is already a numpy array
Attributes
scale ndarray shape nfeatures Per feature relative scaling of the data
New in version 017 scale attribute
maxabs ndarray shape nfeatures Per feature maximum absolute value
nsamplesseen int The number of samples processed by the estimator Will be reset on
new calls to fit but increments across partialfit calls
See also
maxabsscale Equivalent function without the estimator API

Notes
NaNs are treated as missing values disregarded in fit and maintained in transform
For a comparison of the different scalers transformers and normalizers see exam
plespreprocessingplotallscalingpy
Examples
```
 from sklearnpreprocessing import MaxAbsScaler
X   1 1 2
  2 0 0
  0 1 1
transformer  MaxAbsScalerfitX
transformer
MaxAbsScalercopyTrue
transformertransformX

```
Methods
fitself X y Compute the maximum absolute value to be used for
later scaling
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
inversetransform self X Scale back the data to the original representation
partialfit self X y Online computation of max absolute value of X for later
scaling
setparams self params Set the parameters of this estimator
transform self X Scale the data
init selfcopyTrue
fitselfXyNone
Compute the maximum absolute value to be used for later scaling
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The data used to compute the
perfeature minimum and maximum used for later scaling along the features axis
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns

Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Scale back the data to the original representation
Parameters
Xarraylike sparse matrix The data that should be transformed back
partialfit selfXyNone
Online computation of max absolute value of X for later scaling All of X is processed as a single batch
This is intended for cases when fit is not feasible due to very large number of nsamples or because X
is read from a continuous stream
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The data used to compute the
mean and standard deviation used for later scaling along the features axis
yIgnored
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Scale the data
Parameters
Xarraylike sparse matrix The data that should be scaled
Examples using sklearnpreprocessingMaxAbsScaler
•Compare the effect of different scalers on data with outliers
6349sklearnpreprocessing MinMaxScaler
classsklearnpreprocessing MinMaxScaler featurerange0 1copyTrue
Transforms features by scaling each feature to a given range
This estimator scales and translates each feature individually such that it is in the given range on the training set
eg between zero and one

The transformation is given by
Xstd X Xminaxis0 Xmaxaxis0 Xminaxis0
Xscaled Xstd max min min
where min max featurerange
The transformation is calculated as
Xscaled scale X min Xminaxis0 scale
where scale max min Xmaxaxis0 Xminaxis0
This transformation is often used as an alternative to zero mean unit variance scaling
Read more in the User Guide
Parameters
featurerange tuple min max default0 1 Desired range of transformed data
copy boolean optional default True Set to False to perform inplace row normalization and
avoid a copy if the input is already a numpy array
Attributes
min ndarray shape nfeatures Per feature adjustment for minimum Equivalent to min
Xminaxis0 selfscale
scale ndarray shape nfeatures Per feature relative scaling of the data Equivalent to max
 min Xmaxaxis0 Xminaxis0
New in version 017 scale attribute
datamin ndarray shape nfeatures Per feature minimum seen in the data
New in version 017 datamin
datamax ndarray shape nfeatures Per feature maximum seen in the data
New in version 017 datamax
datarange ndarray shape nfeatures Per feature range datamax
datamin seen in the data
New in version 017 datarange
See also
minmaxscale Equivalent function without the estimator API
Notes
NaNs are treated as missing values disregarded in fit and maintained in transform
For a comparison of the different scalers transformers and normalizers see exam

Methods

fitself X y Compute the minimum and maximum to be used for later scaling

fittransform self X y Fit to data then transform it

getparams self deep Get parameters for this estimator

inversetransform self X Undo the scaling of X according to featurerange

partialfit self X y Online computation of min and max on X for later scaling

setparams self params Set the parameters of this estimator

transform self X Scaling features of X according to featurerange

init selffeaturerange0 1copyTrue

fitselfXyNone

Compute the minimum and maximum to be used for later scaling

Parameters

Xarraylike shape nsamples nfeatures The data used to compute the perfeature minimum and maximum used for later scaling along the features axis

fittransform selfXyNone fitparams

Fit to data then transform it

Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X

Parameters

Xnumpy array of shape nsamples nfeatures Training set

ynumpy array of shape nsamples Target values

Returns

Xnew numpy array of shape nsamples nfeaturesnew Transformed array

getparams selfdeepTrue

Get parameters for this estimator

Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Undo the scaling of X according to featurerange
Parameters
Xarraylike shape nsamples nfeatures Input data that will be transformed It cannot
be sparse
partialfit selfXyNone
Online computation of min and max on X for later scaling All of X is processed as a single batch This is
intended for cases when fit is not feasible due to very large number of nsamples or because X is read
from a continuous stream
Parameters
Xarraylike shape nsamples nfeatures The data used to compute the mean and stan
dard deviation used for later scaling along the features axis
yIgnored
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Scaling features of X according to featurerange
Parameters
Xarraylike shape nsamples nfeatures Input data that will be transformed
Examples using sklearnpreprocessingMinMaxScaler
•Compare Stochastic learning strategies for MLPClassifier
•Compare the effect of different scalers on data with outliers
63410sklearnpreprocessing Normalizer
classsklearnpreprocessing Normalizer norm’l2’ copyTrue
Normalize samples individually to unit norm
Each sample ie each row of the data matrix with at least one non zero component is rescaled independently
of other samples so that its norm l1 or l2 equals one
This transformer is able to work both with dense numpy arrays and scipysparse matrix use CSR format if you
want to avoid the burden of a copy conversion

Scaling inputs to unit norms is a common operation for text classification or clustering for instance For instance
the dot product of two l2normalized TFIDF vectors is the cosine similarity of the vectors and is the base
similarity metric for the Vector Space Model commonly used by the Information Retrieval community
Read more in the User Guide
Parameters
norm ‘l1’ ‘l2’ or ‘max’ optional ‘l2’ by default The norm to use to normalize each non
zero sample
copy boolean optional default True set to False to perform inplace row normalization and
avoid a copy if the input is already a numpy array or a scipysparse CSR matrix
See also
normalize Equivalent function without the estimator API
Notes
This estimator is stateless besides constructor parameters the fit method does nothing but is useful when used
in a pipeline
For a comparison of the different scalers transformers and normalizers see exam
plespreprocessingplotallscalingpy
Examples
from sklearnpreprocessing import Normalizer
X 4 1 2 2
1 3 9 3
5 7 5 1

transformer
NormalizercopyTrue norml2
transformertransformX
array08 02 04 04
01 03 09 03
05 07 05 01
Methods
fitself X y Do nothing and return the estimator unchanged
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator
transform self X copy Scale each non zero row of X to unit norm
init selfnorm’l2’ copyTrue
fitselfXyNone
Do nothing and return the estimator unchanged
This method is just there to implement the usual API and hence work in pipelines

Parameters
Xarraylike
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfXcopyNone
Scale each non zero row of X to unit norm
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The data to normalize row
by row scipysparse matrices should be in CSR format to avoid an unnecessary copy
copy bool optional default None Copy the input X or not
Examples using sklearnpreprocessingNormalizer
•Compare the effect of different scalers on data with outliers
•Clustering text documents using kmeans

63411sklearnpreprocessing OneHotEncoder
classsklearnpreprocessing OneHotEncoder nvaluesNone categoricalfeaturesNone
categoriesNone dropNone sparseTrue
dtypeclass ‘numpyfloat64’ han
dleunknown’error’
Encode categorical integer features as a onehot numeric array
The input to this transformer should be an arraylike of integers or strings denoting the values taken on by categorical discrete features The features are encoded using a onehot aka ‘oneofK’ or ‘dummy’ encoding scheme This creates a binary column for each category and returns a sparse matrix or dense array
By default the encoder derives the categories based on the unique values in each feature Alternatively you can also specify the categories manually The OneHotEncoder previously assumed that the input features take on values in the range 0 maxvalues This behaviour is deprecated
This encoding is needed for feeding categorical data to many scikitlearn estimators notably linear models and SVMs with the standard kernels
Note a onehot encoding of y labels should use a LabelBinarizer instead
Read more in the User Guide
Parameters
categories ‘auto’ or a list of listsarrays of values default’auto’ Categories unique values per feature
• ‘auto’ Determine categories automatically from the training data
• list categoriesi holds the categories expected in the ith column The passed categories should not mix strings and numeric values within a single feature and should be sorted in case of numeric values
The used categories can be found in the categories attribute
drop ‘first’ or a listarray of shape nfeatures defaultNone Specifies a methodology to use to drop one of the categories per feature This is useful in situations where perfectly collinear features cause problems such as when feeding the resulting data into a neural network or an unregularized regression
• None retain all features the default
• ‘first’ drop the first category in each feature If only one category is present the feature will be dropped entirely
• array dropi is the category in feature X i that should be dropped
sparse boolean defaultTrue Will return sparse matrix if set True else will return an array
dtype number type defaultnpfloat Desired dtype of output
handleunknown ‘error’ or ‘ignore’ default’error’ Whether to raise an error or ignore if an unknown categorical feature is present during transform default is to raise When this parameter is set to ‘ignore’ and an unknown category is encountered during transform the resulting onehot encoded columns for this feature will be all zeros In the inverse transform an unknown category will be denoted as None
nvalues ‘auto’ int or array of ints default’auto’ Number of values per feature
• ‘auto’ determine value range from training data
•intnumber of categorical values per feature Each feature value should be in rangenvalues

•array nvaluesi is the number of categorical values in X i Each feature
value should be in rangenvaluesi
Deprecated since version 020 The nvalues keyword was deprecated in version 020
and will be removed in 022 Use categories instead
categoricalfeatures ‘all’ or array of indices or mask default‘all’ Specify what features are
treated as categorical
• ‘all’ All features are treated as categorical
• array of indices Array of categorical feature indices
• mask Array of length nfeatures and with dtypebool
Noncategorical features are always stacked to the right of the matrix
Deprecated since version 020 The categoricalfeatures keyword was deprecated
in version 020 and will be removed in 022 You can use the ColumnTransformer
instead
Attributes
categories list of arrays The categories of each feature determined during fitting in order
of the features in X and corresponding with the output of transform This includes the
category specified in drop if any
dropidx array of shape nfeatures dropidxi is the index in categoriesi
of the category to be dropped for each feature None if all the transformed features will be
retained
activefeatures array Indices for active features meaning values that actually occur in the
training set Only available when nvalues is auto
Deprecated since version 020 The activefeatures attribute was deprecated in ver
sion 020 and will be removed in 022
featureindices array of shape nfeatures Indices to feature ranges Feature
iin the original data is mapped to features from featureindicesi to
featureindicesi1 and then potentially masked by activefeatures af
terwards
Deprecated since version 020 The featureindices attribute was deprecated in ver
sion 020 and will be removed in 022
nvalues array of shape nfeatures Maximum number of values per feature
Deprecated since version 020 The nvalues attribute was deprecated in version 020
and will be removed in 022

fitselfXyNone
Fit OneHotEncoder to X
Parameters
Xarraylike shape nsamples nfeatures The data to determine the categories of each

feature
Returns
self
fittransform selfXyNone
Fit OneHotEncoder to X then transform X
Equivalent to fitXtransformX but more convenient
Parameters
Xarraylike shape nsamples nfeatures The data to encode
Returns
Xout sparse matrix if sparseTrue else a 2d array Transformed input
getfeaturenames selfinputfeaturesNone
Return feature names for output features
Parameters
inputfeatures list of string length nfeatures optional String names for input features if
available By default “x0” “x1” “xnfeatures” is used
Returns
outputfeaturenames array of string length noutputfeatures
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Convert the back data to the original representation
In case unknown categories are encountered all zeros in the onehot encoding None is used to represent
this category
Parameters
Xarraylike or sparse matrix shape nsamples nencodedfeatures The transformed
data
Returns
Xtr arraylike shape nsamples nfeatures Inverse transformed array
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

transform selfX
Transform X using onehot encoding
Parameters
Xarraylike shape nsamples nfeatures The data to encode
Returns
Xout sparse matrix if sparseTrue else a 2d array Transformed input
Examples using sklearnpreprocessingOneHotEncoder
•Column Transformer with Mixed Types
•Feature transformations with ensembles of trees
63412sklearnpreprocessing OrdinalEncoder
classsklearnpreprocessing OrdinalEncoder categories'auto' dtypeclass
'numpyfloat64'
Encode categorical features as an integer array
The input to this transformer should be an arraylike of integers or strings denoting the values taken on by
categorical discrete features The features are converted to ordinal integers This results in a single column of
integers 0 to ncategories 1 per feature
Read more in the User Guide
Parameters
categories 'auto' or a list of listsarrays of values Categories unique values per feature
• 'auto' Determine categories automatically from the training data
• list categoriesi holds the categories expected in the ith column The passed
categories should not mix strings and numeric values and should be sorted in case of
numeric values
The used categories can be found in the categories attribute
dtype number type default npfloat64 Desired dtype of output
Attributes
categories list of arrays The categories of each feature determined during fitting in order of
the features in X and corresponding with the output of transform
See also
sklearnpreprocessingOneHotEncoder performs a onehot encoding of categorical features
sklearnpreprocessingLabelEncoder encodes target labels with values between 0 and nclasses
1
Examples
Given a dataset with two features we let the encoder find the unique values per feature and transform the data
to an ordinal encoding

```
 from sklearnpreprocessing import OrdinalEncoder
enc  OrdinalEncoder
X  Male 1 Female 3 Female 2
encfitX

OrdinalEncodercategoriesauto dtype numpyfloat64
enccategories

enctransformFemale 3 Male 1
array0 2
1 0
encinversetransform1 0 0 1
arrayMale 1
Female 2 dtypeobject
```
Methods

fitself X y Fit the OrdinalEncoder to X

fittransform self X y Fit to data then transform it

getparams self deep Get parameters for this estimator

inversetransform self X Convert the data back to the original representation

setparams self params Set the parameters of this estimator

transform self X Transform X to ordinal codes

init selfcategories‘auto’ dtypeclass ‘numpyfloat64’

fitselfXyNone

Fit the OrdinalEncoder to X

Parameters

Xarraylike shape nsamples nfeatures The data to determine the categories of each feature

Returns

self

fittransform selfXyNone fitparams

Fit to data then transform it

Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X

Parameters

Xnumpy array of shape nsamples nfeatures Training set

ynumpy array of shape nsamples Target values

Returns

Xnew numpy array of shape nsamples nfeaturesnew Transformed array

getparams selfdeepTrue

Get parameters for this estimator

Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Convert the data back to the original representation
Parameters
Xarraylike or sparse matrix shape nsamples nencodedfeatures The transformed
data
Returns
Xtr arraylike shape nsamples nfeatures Inverse transformed array
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform X to ordinal codes
Parameters
Xarraylike shape nsamples nfeatures The data to encode
Returns
Xout sparse matrix or a 2d array Transformed input
63413sklearnpreprocessing PolynomialFeatures
classsklearnpreprocessing PolynomialFeatures degree2 interactiononlyFalse in
cludebiasTrue order’C’
Generate polynomial and interaction features
Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than
or equal to the specified degree For example if an input sample is two dimensional and of the form a b the
degree2 polynomial features are 1 a b a2 ab b2
Parameters
degree integer The degree of the polynomial features Default 2
interactiononly boolean default False If true only interaction features are produced fea
tures that are products of at most degree distinct input features so not x12
x0x23 etc
includebias boolean If True default then include a bias column the feature in which all
polynomial powers are zero ie a column of ones acts as an intercept term in a linear
model

order str in ‘C’ ‘F’ default ‘C’ Order of output array in the dense case ‘F’ order is faster
to compute but may slow down subsequent estimators
New in version 021
Attributes
powers array shape noutputfeatures ninputfeatures powersi j is the exponent of
the jth input in the ith output
ninputfeatures int The total number of input features
noutputfeatures int The total number of polynomial output features The number of out
put features is computed by iterating over all suitably sized combinations of input features
Notes
Be aware that the number of features in the output array scales polynomially in the number of features of the
input array and exponentially in the degree High degrees can cause overfitting
Seeexampleslinearmodelplotpolynomialinterpolationpy
Examples
```
 import numpy as np
 from sklearnpreprocessing import PolynomialFeatures
X  nparange6reshape3 2
X
array0 1
2 3
4 5
poly  PolynomialFeatures2
polyfittransformX

 1 2 3 4 6 9
 1 4 5 16 20 25
poly  PolynomialFeaturesinteractiononly True
polyfittransformX
array 1 0 1 0
 1 2 3 6
 1 4 5 20
```
Methods
fitself X y Compute number of output features
fittransform self X y Fit to data then transform it
getfeaturenames self inputfeatures Return feature names for output features
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator
transform self X Transform data to polynomial features
init selfdegree2 interactiononlyFalse includebiasTrue order‘C’
fitselfXyNone

Compute number of output features
Parameters
Xarraylike shape nsamples nfeatures The data
Returns
self instance
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getfeaturenames selfinputfeaturesNone
Return feature names for output features
Parameters
inputfeatures list of string length nfeatures optional String names for input features if
available By default “x0” “x1” “xnfeatures” is used
Returns
outputfeaturenames list of string length noutputfeatures
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Transform data to polynomial features
Parameters
Xarraylike or CSRCSC sparse matrix shape nsamples nfeatures The data to trans
form row by row

Prefer CSR over CSC for sparse input for speed but CSC is required if the degree is 4
or higher If the degree is less than 4 and the input format is CSC it will be converted to
CSR have its polynomial features generated then converted back to CSC
If the degree is 2 or 3 the method described in “Leveraging Sparsity to Speed Up Polyno
mial Feature Expansions of CSR Matrices Using KSimplex Numbers” by Andrew Nys
trom and John Hughes is used which is much faster than the method used on CSC input
For this reason a CSC input will be converted to CSR and the output will be converted
back to CSC prior to being returned hence the preference of CSR
Returns
XPnpndarray or CSRCSC sparse matrix shape nsamples NP The matrix of features
where NP is the number of polynomial features generated from the combination of inputs
Examples using sklearnpreprocessingPolynomialFeatures
•Polynomial interpolation
•Robust linear estimator fitting
•Underfitting vs Overfitting
63414sklearnpreprocessing PowerTransformer
classsklearnpreprocessing PowerTransformer method’yeojohnson’ standardizeTrue
copyTrue
Apply a power transform featurewise to make data more Gaussianlike
Power transforms are a family of parametric monotonic transformations that are applied to make data more
Gaussianlike This is useful for modeling issues related to heteroscedasticity nonconstant variance or other
situations where normality is desired
Currently PowerTransformer supports the BoxCox transform and the YeoJohnson transform The optimal
parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood
BoxCox requires input data to be strictly positive while YeoJohnson supports both positive or negative data
By default zeromean unitvariance normalization is applied to the transformed data
Read more in the User Guide
Parameters
method str default’yeojohnson’ The power transform method Available methods are
• ‘yeojohnson’ Rf3e1504535de1 works with positive and negative values
• ‘boxcox’ Rf3e1504535de2 only works with strictly positive values
standardize boolean defaultTrue Set to True to apply zeromean unitvariance normaliza
tion to the transformed output
copy boolean optional defaultTrue Set to False to perform inplace computation during
transformation
Attributes
lambdas array of float shape nfeatures The parameters of the power transformation for
the selected features
See also

powertransform Equivalent function without the estimator API
QuantileTransformer Maps data to a standard normal distribution with the parameter
outputdistributionnormal
Notes
NaNs are treated as missing values disregarded in fit and maintained in transform
For a comparison of the different scalers transformers and normalizers see exam

X 1 expXtrans
Parameters
Xarraylike shape nsamples nfeatures The transformed data
Returns
Xarraylike shape nsamples nfeatures The original data
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Apply the power transform to each feature using the fitted lambdas

Parameters
Xarraylike shape nsamples nfeatures The data to be transformed using a power
transformation
Returns
Xtrans arraylike shape nsamples nfeatures The transformed data
Examples using sklearnpreprocessingPowerTransformer
•Map data to a normal distribution
•Compare the effect of different scalers on data with outliers
63415sklearnpreprocessing QuantileTransformer
classsklearnpreprocessing QuantileTransformer nquantiles1000 out
putdistribution’uniform’ ig
noreimplicitzerosFalse subsam
ple100000 randomstateNone
copyTrue
Transform features using quantiles information
This method transforms the features to follow a uniform or a normal distribution Therefore for a given feature
this transformation tends to spread out the most frequent values It also reduces the impact of marginal outliers
this is therefore a robust preprocessing scheme
The transformation is applied on each feature independently First an estimate of the cumulative distribution
function of a feature is used to map the original values to a uniform distribution The obtained values are then
mapped to the desired output distribution using the associated quantile function Features values of newunseen
data that fall below or above the fitted range will be mapped to the bounds of the output distribution Note that
this transform is nonlinear It may distort linear correlations between variables measured at the same scale but
renders variables measured at different scales more directly comparable
Read more in the User Guide
Parameters
nquantiles int optional default1000 or nsamples Number of quantiles to be computed
It corresponds to the number of landmarks used to discretize the cumulative distribution
function If nquantiles is larger than the number of samples nquantiles is set to the
number of samples as a larger number of quantiles does not give a better approximation of
the cumulative distribution function estimator
outputdistribution str optional default’uniform’ Marginal distribution for the trans
formed data The choices are ‘uniform’ default or ‘normal’
ignoreimplicitzeros bool optional defaultFalse Only applies to sparse matrices If True
the sparse entries of the matrix are discarded to compute the quantile statistics If False
these entries are treated as zeros
subsample int optional default1e5 Maximum number of samples used to estimate the
quantiles for computational efficiency Note that the subsampling procedure may differ
for valueidentical sparse and dense matrices
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is

the RandomState instance used by nprandom Note that this is used by subsampling and
smoothing noise
copy boolean optional defaultTrue Set to False to perform inplace transformation and
avoid a copy if the input is already a numpy array
Attributes

along the features axis If a sparse matrix is provided it will be converted into
a sparsecscmatrix Additionally the sparse matrix needs to be nonnegative if
ignoreimplicitzeros is False
Returns
Xtndarray or sparse matrix shape nsamples nfeatures The projected data
Examples using sklearnpreprocessingQuantileTransformer
•Effect of transforming the targets in regression model
•Map data to a normal distribution
•Compare the effect of different scalers on data with outliers
63416sklearnpreprocessing RobustScaler
classsklearnpreprocessing RobustScaler withcenteringTrue withscalingTrue quan
tilerange250 750 copyTrue
Scale features using statistics that are robust to outliers
This Scaler removes the median and scales the data according to the quantile range defaults to IQR Interquartile
Range The IQR is the range between the 1st quartile 25th quantile and the 3rd quartile 75th quantile
Centering and scaling happen independently on each feature by computing the relevant statistics on the samples
in the training set Median and interquartile range are then stored to be used on later data using the transform
method
Standardization of a dataset is a common requirement for many machine learning estimators Typically this is
done by removing the mean and scaling to unit variance However outliers can often influence the sample mean
 variance in a negative way In such cases the median and the interquartile range often give better results
New in version 017
Read more in the User Guide
Parameters
withcentering boolean True by default If True center the data before scaling This will
causetransform to raise an exception when attempted on sparse matrices because cen
tering them entails building a dense matrix which in common use cases is likely to be too
large to fit in memory
withscaling boolean True by default If True scale the data to interquartile range
quantilerange tuple qmin qmax 00 qmin qmax 1000 Default 250 750
1st quantile 3rd quantile IQR Quantile range used to calculate scale
New in version 018
copy boolean optional default is True If False try to avoid a copy and do inplace scaling
instead This is not guaranteed to always work inplace eg if the data is not a NumPy array
or scipysparse CSR matrix a copy may still be returned

Attributes
center array of floats The median value for each feature in the training set
scale array of floats The scaled interquartile range for each feature in the training set
New in version 017 scale attribute

Returns
params mapping of string to any Parameter names mapped to their values
inversetransform selfX
Scale back the data to the original representation
Parameters
Xarraylike The data used to scale along the specified axis
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Center and scale the data
Parameters
Xarraylike sparse matrix The data used to scale along the specified axis
Examples using sklearnpreprocessingRobustScaler
•Compare the effect of different scalers on data with outliers
63417sklearnpreprocessing StandardScaler
classsklearnpreprocessing StandardScaler copyTrue withmeanTrue withstdTrue
Standardize features by removing the mean and scaling to unit variance

The standard score of a sample xis calculated as
z x u s
whereuis the mean of the training samples or zero if withmeanFalse andsis the standard deviation of the training samples or one if withstdFalse
Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set Mean and standard deviation are then stored to be used on later data using the transform method
Standardization of a dataset is a common requirement for many machine learning estimators they might behave badly if the individual features do not more or less look like standard normally distributed data eg Gaussian with 0 mean and unit variance
For instance many elements used in the objective function of a learning algorithm such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models assume that all features are centered around 0 and have variance in the same order If a feature has a variance that is orders of magnitude larger that others it might dominate the objective function and make the estimator unable to learn from other features correctly as expected
This scaler can also be applied to sparse CSR or CSC matrices by passing withmeanFalse to avoid breaking the sparsity structure of the data
Read more in the User Guide
Parameters
copy boolean optional default True If False try to avoid a copy and do inplace scaling in stead This is not guaranteed to always work inplace eg if the data is not a NumPy array or scipysparse CSR matrix a copy may still be returned
withmean boolean True by default If True center the data before scaling This does not work and will raise an exception when attempted on sparse matrices because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory
withstd boolean True by default If True scale the data to unit variance or equivalently unit standard deviation
Attributes
scale ndarray or None shape nfeatures Per feature relative scaling of the data This is calculated using npsqrtvar Equal toNone whenwithstdFalse
New in version 017 scale
mean ndarray or None shape nfeatures The mean value for each feature in the training set Equal to None whenwithmeanFalse
var ndarray or None shape nfeatures The variance for each feature in the training set Used to compute scale Equal toNone whenwithstdFalse
nsamplesseen int or array shape nfeatures The number of samples processed by the estimator for each feature If there are not missing samples the nsamplesseen will be an integer otherwise it will be an array Will be reset on new calls to fit but increments acrosspartialfit calls

63420sklearnpreprocessing labelbinarize
sklearnpreprocessing labelbinarize y classes neglabel0 poslabel1
sparseoutputFalse
Binarize labels in a onevsall fashion

Several regression and binary classification algorithms are available in scikitlearn A simple way to extend these algorithms to the multiclass classification case is to use the socalled onevsall scheme
This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time
Parameters
yarraylike Sequence of integer labels or multilabel data to encode
classes arraylike of shape nclasses Uniquely holds the label for each class
neglabel int default 0 Value with which negative labels must be encoded
poslabel int default 1 Value with which positive labels must be encoded
sparseoutput boolean default False Set to true if output binary array is desired in CSR sparse format
Returns
Ynumpy array or CSR matrix of shape nsamples nclasses Shape will be nsamples 1 for binary problems
See also

•PrecisionRecall

63421sklearnpreprocessing maxabsscale
sklearnpreprocessing maxabsscale Xaxis0 copyTrue
Scale each feature to the 1 1 range without breaking the sparsity
This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 10
This scaler can also be applied to sparse CSR or CSC matrices
Parameters
Xarraylike shape nsamples nfeatures The data
axis int 0 by default axis used to scale along If 0 independently scale each feature otherwise if 1 scale each sample
copy boolean optional default is True Set to False to perform inplace scaling and avoid a copy if the input is already a numpy array
See also
MaxAbsScaler Performs scaling to the 1 1 range using the‘‘Transformer‘‘ API eg as part of a preprocessingsklearnpipelinePipeline
Notes
NaNs are treated as missing values disregarded to compute the statistics and maintained during the data transformation
For a comparison of the different scalers transformers and normalizers see examplespreprocessingplotallscalingpy
63422sklearnpreprocessing minmaxscale
sklearnpreprocessing minmaxscale Xfeaturerange0 1axis0 copyTrue
Transforms features by scaling each feature to a given range
This estimator scales and translates each feature individually such that it is in the given range on the training set ie between zero and one
The transformation is given by when axis0
Xstd X Xminaxis0 Xmaxaxis0 Xminaxis0
Xscaled Xstd max min min
where min max featurerange
The transformation is calculated as when axis0
Xscaled scale X min Xminaxis0 scale
where scale max min Xmaxaxis0 Xminaxis0
This transformation is often used as an alternative to zero mean unit variance scaling
Read more in the User Guide
New in version 017 minmaxscale function interface to sklearnpreprocessingMinMaxScaler
Parameters

Xarraylike shape nsamples nfeatures The data
featurerange tuple min max default0 1 Desired range of transformed data
axis int 0 by default axis used to scale along If 0 independently scale each feature other
wise if 1 scale each sample
copy boolean optional default is True Set to False to perform inplace scaling and avoid a
copy if the input is already a numpy array
See also
MinMaxScaler Performs scaling to a given range using the‘‘Transformer‘‘ API eg as part of a preprocess

•Compare the effect of different scalers on data with outliers
63423sklearnpreprocessing normalize
sklearnpreprocessing normalize Xnorm‘l2’ axis1 copyTrue returnnormFalse
Scale input vectors individually to unit norm vector length
Read more in the User Guide
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The data to normalize element
by element scipysparse matrices should be in CSR format to avoid an unnecessary copy
norm ‘l1’ ‘l2’ or ‘max’ optional ‘l2’ by default The norm to use to normalize each non
zero sample or each nonzero feature if axis is 0
axis 0 or 1 optional 1 by default axis used to normalize the data along If 1 independently
normalize each sample otherwise if 0 normalize each feature
copy boolean optional default True set to False to perform inplace row normalization and
avoid a copy if the input is already a numpy array or a scipysparse CSR matrix and if axis
is 1
returnnorm boolean default False whether to return the computed norms
Returns
Xarraylike sparse matrix shape nsamples nfeatures Normalized input X
norms array shape nsamples if axis1 else nfeatures An array of norms along given
axis for X When X is sparse a NotImplementedError will be raised for norm ‘l1’ or ‘l2’

63424sklearnpreprocessing quantiletransform
sklearnpreprocessing quantiletransform X axis0 nquantiles1000 out
putdistribution’uniform’ ig
noreimplicitzerosFalse subsample100000
randomstateNone copy’warn’
Transform features using quantiles information
This method transforms the features to follow a uniform or a normal distribution Therefore for a given feature
this transformation tends to spread out the most frequent values It also reduces the impact of marginal outliers
this is therefore a robust preprocessing scheme
The transformation is applied on each feature independently First an estimate of the cumulative distribution
function of a feature is used to map the original values to a uniform distribution The obtained values are then
mapped to the desired output distribution using the associated quantile function Features values of newunseen
data that fall below or above the fitted range will be mapped to the bounds of the output distribution Note that
this transform is nonlinear It may distort linear correlations between variables measured at the same scale but
renders variables measured at different scales more directly comparable
Read more in the User Guide
Parameters
Xarraylike sparse matrix The data to transform
axis int default0 Axis used to compute the means and standard deviations along If 0
transform each feature otherwise if 1 transform each sample
nquantiles int optional default1000 or nsamples Number of quantiles to be computed
It corresponds to the number of landmarks used to discretize the cumulative distribution
function If nquantiles is larger than the number of samples nquantiles is set to the
number of samples as a larger number of quantiles does not give a better approximation of
the cumulative distribution function estimator
outputdistribution str optional default’uniform’ Marginal distribution for the trans
formed data The choices are ‘uniform’ default or ‘normal’
ignoreimplicitzeros bool optional defaultFalse Only applies to sparse matrices If True
the sparse entries of the matrix are discarded to compute the quantile statistics If False
these entries are treated as zeros
subsample int optional default1e5 Maximum number of samples used to estimate the
quantiles for computational efficiency Note that the subsampling procedure may differ
for valueidentical sparse and dense matrices
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Note that this is used by subsampling and
smoothing noise
copy boolean optional default”warn” Set to False to perform inplace transformation and
avoid a copy if the input is already a numpy array If True a copy of Xis transformed
leaving the original Xunchanged

Deprecated since version 021 The default value of parameter copy will be changed from
False to True in 023 The current default of False is being changed to make it more con
sistent with the default copy values of other functions in sklearnpreprocessing
data Furthermore the current default of False may have unexpected side effects by mod
ifying the value of Xinplace
Returns
Xtndarray or sparse matrix shape nsamples nfeatures The transformed data

63425sklearnpreprocessing robustscale
sklearnpreprocessing robustscale Xaxis0 withcenteringTrue withscalingTrue
quantilerange250 750 copyTrue
Standardize a dataset along any axis
Center to the median and component wise scale according to the interquartile range
Read more in the User Guide
Parameters
Xarraylike The data to center and scale

axis int 0 by default axis used to compute the medians and IQR along If 0 independently
scale each feature otherwise if 1 scale each sample
withcentering boolean True by default If True center the data before scaling
withscaling boolean True by default If True scale the data to unit variance or equivalently
unit standard deviation
quantilerange tuple qmin qmax 00 qmin qmax 1000 Default 250 750
1st quantile 3rd quantile IQR Quantile range used to calculate scale
New in version 018
copy boolean optional default is True set to False to perform inplace row normalization and
avoid a copy if the input is already a numpy array or a scipysparse CSR matrix and if axis
is 1
See also
RobustScaler Performs centering and scaling using the Transformer API eg as part of a preprocess
ingsklearnpipelinePipeline
Notes
This implementation will refuse to center scipysparse matrices since it would make them nonsparse and would
potentially crash the program with memory exhaustion problems
Instead the caller is expected to either set explicitly withcenteringFalse in that case only variance
scaling will be performed on the features of the CSR matrix or to call Xtoarray if heshe expects the
materialized dense array to fit in memory
To avoid memory copy the caller should pass a CSR matrix
For a comparison of the different scalers transformers and normalizers see exam
plespreprocessingplotallscalingpy
63426sklearnpreprocessing scale
sklearnpreprocessing scaleXaxis0 withmeanTrue withstdTrue copyTrue
Standardize a dataset along any axis
Center to the mean and component wise scale to unit variance
Read more in the User Guide
Parameters
Xarraylike sparse matrix The data to center and scale
axis int 0 by default axis used to compute the means and standard deviations along If 0
independently standardize each feature otherwise if 1 standardize each sample
withmean boolean True by default If True center the data before scaling
withstd boolean True by default If True scale the data to unit variance or equivalently unit
standard deviation
copy boolean optional default True set to False to perform inplace row normalization and
avoid a copy if the input is already a numpy array or a scipysparse CSC matrix and if axis
is 1

See also
StandardScaler Performs scaling to unit variance using the‘‘Transformer‘‘ API eg as part of a prepro
cessingsklearnpipelinePipeline
Notes
This implementation will refuse to center scipysparse matrices since it would make them nonsparse and would
potentially crash the program with memory exhaustion problems
Instead the caller is expected to either set explicitly withmeanFalse in that case only variance scaling
will be performed on the features of the CSC matrix or to call Xtoarray if heshe expects the materialized
dense array to fit in memory
To avoid memory copy the caller should pass a CSC matrix
NaNs are treated as missing values disregarded to compute the statistics and maintained during the data trans
formation
We use a biased estimator for the standard deviation equivalent to numpystdx ddof0 Note that the
choice ofddof is unlikely to affect model performance
For a comparison of the different scalers transformers and normalizers see exam
plespreprocessingplotallscalingpy
Examples using sklearnpreprocessingscale
•A demo of KMeans clustering on the handwritten digits data
63427sklearnpreprocessing powertransform
sklearnpreprocessing powertransform Xmethod’warn’ standardizeTrue copyTrue
Power transforms are a family of parametric monotonic transformations that are applied to make data more
Gaussianlike This is useful for modeling issues related to heteroscedasticity nonconstant variance or other
situations where normality is desired
Currently powertransform supports the BoxCox transform and the YeoJohnson transform The optimal pa
rameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood
BoxCox requires input data to be strictly positive while YeoJohnson supports both positive or negative data
By default zeromean unitvariance normalization is applied to the transformed data
Read more in the User Guide
Parameters
Xarraylike shape nsamples nfeatures The data to be transformed using a power trans
formation
method str The power transform method Available methods are
• ‘yeojohnson’ 1 works with positive and negative values
• ‘boxcox’ 2 only works with strictly positive values
The default method will be changed from ‘boxcox’ to ‘yeojohnson’ in version 023 To
suppress the FutureWarning explicitly set the parameter

standardize boolean defaultTrue Set to True to apply zeromean unitvariance normaliza
tion to the transformed output
copy boolean optional defaultTrue Set to False to perform inplace computation during
transformation
Returns
Xtrans arraylike shape nsamples nfeatures The transformed data
See also
PowerTransformer Equivalent transformation with the Transformer API eg as part of a preprocess
ingsklearnpipelinePipeline
quantiletransform Maps data to a standard normal distribution with the parameter
outputdistributionnormal
Notes
NaNs are treated as missing values disregarded in fit and maintained in transform
For a comparison of the different scalers transformers and normalizers see exam

635sklearnrandomprojection Random projection
Random Projection transformers
Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading
a controlled amount of accuracy as additional variance for faster processing times and smaller model sizes
The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances
between any two samples of the dataset
The main theoretical result behind the efficiency of random projection is the JohnsonLindenstrauss lemma quoting
Wikipedia

In mathematics the JohnsonLindenstrauss lemma is a result concerning lowdistortion embeddings of points from highdimensional into lowdimensional Euclidean space The lemma states that a small set of points in a highdimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved The map used for the embedding is at least Lipschitz and can even be taken to be an orthogonal projection
User guide See the Random Projection section for further details

6351sklearnrandomprojection GaussianRandomProjection
classsklearnrandomprojection GaussianRandomProjection ncomponents’auto’ eps01 ran domstateNone
Reduce dimensionality through Gaussian random projection
The components of the random matrix are drawn from N0 1 ncomponents
Read more in the User Guide
Parameters
ncomponents int or ‘auto’ optional default ‘auto’ Dimensionality of the target projection space
ncomponents can be automatically adjusted according to the number of samples in the dataset and the bound given by the JohnsonLindenstrauss lemma In that case the quality of the embedding is controlled by the eps parameter
It should be noted that JohnsonLindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset
eps strictly positive float optional default01 Parameter to control the quality of the embed ding according to the JohnsonLindenstrauss lemma when ncomponents is set to ‘auto’ Smaller values lead to better embedding and higher number of dimensions ncomponents in the target projection space
randomstate int RandomState instance or None optional defaultNone Control the pseudo random number generator used to generate the matrix at fit time If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
Attributes
ncomponent int Concrete number of components computed when ncomponents”auto”
components numpy array of shape ncomponents nfeatures Random matrix used for the projection

setparams self params Set the parameters of this estimator
transform self X Project the data by using matrix product with the ran
dom matrix
init selfncomponents’auto’ eps01 randomstateNone
fitselfXyNone
Generate a sparse random projection matrix
Parameters
Xnumpy array or scipysparse of shape nsamples nfeatures Training set only the
shape is used to find optimal random matrix dimensions based on the theory referenced in
the afore mentioned papers
yIgnored
Returns
self
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators

Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Project the data by using matrix product with the random matrix
Parameters
Xnumpy array or scipysparse of shape nsamples nfeatures The input data to project
into a smaller dimensional space
Returns
Xnew numpy array or scipy sparse of shape nsamples ncomponents Projected array
6352sklearnrandomprojection SparseRandomProjection
classsklearnrandomprojection SparseRandomProjection ncomponents’auto’
density’auto’ eps01
denseoutputFalse ran
domstateNone
Reduce dimensionality through sparse random projection
Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding
quality while being much more memory efficient and allowing faster computation of the projected data
If we notes 1 density the components of the random matrix are drawn from
• sqrts sqrtncomponents with probability 1 2s
• 0 with probability 1 1 s
• sqrts sqrtncomponents with probability 1 2s
Read more in the User Guide
Parameters
ncomponents int or ‘auto’ optional default ‘auto’ Dimensionality of the target projection
space
ncomponents can be automatically adjusted according to the number of samples in the
dataset and the bound given by the JohnsonLindenstrauss lemma In that case the quality
of the embedding is controlled by the eps parameter
It should be noted that JohnsonLindenstrauss lemma can yield very conservative estimated
of the required number of components as it makes no assumption on the structure of the
dataset
density float in range 0 1 optional default’auto’ Ratio of nonzero component in the
random projection matrix
635sklearnrandomprojection Random projection 2289

If density ‘auto’ the value is set to the minimum density as recommended by Ping Li et
al 1 sqrtnfeatures
Use density 1 30 if you want to reproduce the results from Achlioptas 2001
eps strictly positive float optional default01 Parameter to control the quality of the em
bedding according to the JohnsonLindenstrauss lemma when ncomponents is set to ‘auto’
Smaller values lead to better embedding and higher number of dimensions ncomponents
in the target projection space
denseoutput boolean optional defaultFalse If True ensure that the output of the random
projection is a dense numpy array even if the input and random projection matrix are both
sparse In practice if the number of components is small the number of zero components in
the projected data will be very small and it will be more CPU and memory efficient to use a
dense representation
If False the projected data uses a sparse representation if the input is sparse
randomstate int RandomState instance or None optional defaultNone Control the
pseudo random number generator used to generate the matrix at fit time If int randomstate
is the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
Attributes
ncomponent int Concrete number of components computed when ncomponents”auto”
components CSR matrix with shape ncomponents nfeatures Random matrix used for
the projection
density float in range 00 10 Concrete density computed from when density “auto”

johnsonlindenstraussmindim Find a ‘safe’ number of components to randomly project to
6353sklearnrandomprojection johnsonlindenstraussmindim
sklearnrandomprojection johnsonlindenstraussmindim nsamples eps01
Find a ‘safe’ number of components to randomly project to
The distortion introduced by a random projection ponly changes the distance between two points by a factor 1
eps in an euclidean space with good probability The projection pis an epsembedding as defined by
1 eps u v2 pu pv2 1 eps u v2
Where u and v are any rows taken from a dataset of shape nsamples nfeatures eps is in 0 1 and p is a
projection by a random Gaussian N0 1 matrix with shape ncomponents nfeatures or a sparse Achlioptas
matrix
The minimum number of components to guarantee the epsembedding is given by
ncomponents 4 lognsamples eps2 2 eps3 3
Note that the number of dimensions is independent of the original number of features but instead depends on
the size of the dataset the larger the dataset the higher is the minimal dimensionality of an epsembedding
Read more in the User Guide
Parameters
nsamples int or numpy array of int greater than 0 Number of samples If an array is given
it will compute a safe number of components arraywise
eps float or numpy array of float in 01 optional default01 Maximum distortion rate as
defined by the JohnsonLindenstrauss lemma If an array is given it will compute a safe
number of components arraywise
Returns
ncomponents int or numpy array of int The minimal number of components to guarantee
with good probability an epsembedding with nsamples

C10 multiclass'ovr' fitinterceptTrue interceptscaling1
classweightNone verbose0 randomstateNone maxiter1000
Linear Support Vector Classification
Similar to SVC with parameter kernel'linear' but implemented in terms of liblinear rather than libsvm so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples
This class supports both dense and sparse input and the multiclass support is handled according to a onevsthe rest scheme
Read more in the User Guide
Parameters
penalty string 'l1' or 'l2' default'l2' Specifies the norm used in the penalization The 'l2' penalty is the standard used in SVC The 'l1' leads to coef vectors that are sparse
loss string 'hinge' or 'squaredhinge' default'squaredhinge' Specifies the loss function 'hinge' is the standard SVM loss used eg by the SVC class while 'squaredhinge' is the square of the hinge loss
dual bool defaultTrue Select the algorithm to either solve the dual or primal optimization problem Prefer dualFalse when nsamples nfeatures
tolfloat optional default1e4 Tolerance for stopping criteria
Cfloat optional default10 Penalty parameter C of the error term
multiclass string 'ovr' or 'crammersinger' default'ovr' Determines the multiclass strategy if ycontains more than two classes ovr trains nclasses onevsrest clas sifiers while crammersinger optimizes a joint objective over all classes While crammersinger is interesting from a theoretical perspective as it is consistent it is sel dom used in practice as it rarely leads to better accuracy and is more expensive to compute Ifcrammersinger is chosen the options loss penalty and dual will be ignored
fitintercept boolean optional defaultTrue Whether to calculate the intercept for this model If set to false no intercept will be used in calculations ie data is expected to

be already centered
interceptscaling float optional default1 When selffitintercept is True instance vector
x becomesx selfinterceptscaling ie a “synthetic” feature with constant
value equals to interceptscaling is appended to the instance vector The intercept becomes
interceptscaling synthetic feature weight Note the synthetic feature weight is subject to
l1l2 regularization as all other features To lessen the effect of regularization on synthetic
feature weight and therefore on the intercept interceptscaling has to be increased
classweight dict ‘balanced’ optional Set the parameter C of class i to
classweighti Cfor SVC If not given all classes are supposed to have weight
one The “balanced” mode uses the values of y to automatically adjust weights inversely
proportional to class frequencies in the input data as nsamples nclasses
npbincounty
verbose int default0 Enable verbose output Note that this setting takes advantage of a per
process runtime setting in liblinear that if enabled may not work properly in a multithreaded
context
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator to use when shuffling the data for the dual coordi
nate descent if dualTrue WhendualFalse the underlying implementation of
LinearSVC is not random and randomstate has no effect on the results If int ran
domstate is the seed used by the random number generator If RandomState instance ran
domstate is the random number generator If None the random number generator is the
RandomState instance used by nprandom
maxiter int default1000 The maximum number of iterations to be run
Attributes
coef array shape nfeatures if nclasses 2 else nclasses nfeatures Weights as
signed to the features coefficients in the primal problem This is only available in the case
of a linear kernel
coef is a readonly property derived from rawcoef that follows the internal memory
layout of liblinear
intercept array shape 1 if nclasses 2 else nclasses Constants in decision function
See also
SVC Implementation of Support Vector Machine classifier using libsvm the kernel can be nonlinear but its
SMO algorithm does not scale to large number of samples as LinearSVC does Furthermore SVC multi
class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest It is possible to
implement one vs the rest with SVC by using the sklearnmulticlassOneVsRestClassifier
wrapper Finally SVC can fit dense data without memory copy if the input is Ccontiguous Sparse data
will still incur memory copy though
sklearnlinearmodelSGDClassifier SGDClassifier can optimize the same cost function as Lin
earSVC by adjusting the penalty and loss parameters In addition it requires less memory allows incre
mental online learning and implements various loss functions and regularization regimes
Notes
The underlying C implementation uses a random number generator to select features when fitting the model
It is thus not uncommon to have slightly different results for the same input data If that happens try with a
smallertol parameter

The underlying implementation liblinear uses a sparse internal representation for the data that will incur a memory copy
Predict output may not match that of standalone liblinear in certain cases See differences from liblinear in the narrative documentation

decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns

array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXysampleweightNone
Fit the model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples in the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target vector relative to X
sampleweight arraylike shape nsamples optional Array of weights that are as
signed to individual samples If not provided then each sample is given unit weight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X

sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
Examples using sklearnsvmLinearSVC
•Explicit feature map approximation for RBF kernels
•Comparison of Calibration of Classifiers
•Probability Calibration curves
•Selecting dimensionality reduction with Pipeline and GridSearchCV
•Column Transformer with Heterogeneous Data Sources
•Pipeline Anova SVM
•Balance model complexity and crossvalidated score
•PrecisionRecall
•Feature discretization
•Plot different SVM classifiers in the iris dataset
•Scaling the regularization parameter for SVCs
•Classification of text documents using sparse features

sklearnsvm LinearSVR
classsklearnsvm LinearSVR epsilon00 tol00001 C10 loss’epsiloninsensitive’
fitinterceptTrue interceptscaling10 dualTrue verbose0
randomstateNone maxiter1000
Linear Support Vector Regression
Similar to SVR with parameter kernel’linear’ but implemented in terms of liblinear rather than libsvm so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples
This class supports both dense and sparse input
Read more in the User Guide
Parameters
epsilon float optional default00 Epsilon parameter in the epsiloninsensitive loss function Note that the value of this parameter depends on the scale of the target variable y If unsure setepsilon0
tolfloat optional default1e4 Tolerance for stopping criteria
Cfloat optional default10 Penalty parameter C of the error term The penalty is a squared l2 penalty The bigger this parameter the less regularization is used
loss string optional default’epsiloninsensitive’ Specifies the loss function The epsilon insensitive loss standard SVR is the L1 loss while the squared epsiloninsensitive loss ‘squaredepsiloninsensitive’ is the L2 loss
fitintercept boolean optional defaultTrue Whether to calculate the intercept for this model If set to false no intercept will be used in calculations ie data is expected to be already centered
interceptscaling float optional default1 When selffitintercept is True instance vec tor x becomes x selfinterceptscaling ie a “synthetic” feature with constant value equals to interceptscaling is appended to the instance vector The intercept becomes in terceptscaling synthetic feature weight Note the synthetic feature weight is subject to l1l2 regularization as all other features To lessen the effect of regularization on synthetic feature weight and therefore on the intercept interceptscaling has to be increased
dual bool defaultTrue Select the algorithm to either solve the dual or primal optimization problem Prefer dualFalse when nsamples nfeatures
verbose int default0 Enable verbose output Note that this setting takes advantage of a per process runtime setting in liblinear that if enabled may not work properly in a multithreaded context
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
maxiter int default1000 The maximum number of iterations to be run
Attributes
coef array shape nfeatures if nclasses 2 else nclasses nfeatures Weights as signed to the features coefficients in the primal problem This is only available in the case of a linear kernel

coef is a readonly property derived from rawcoef that follows the internal memory
layout of liblinear
intercept array shape 1 if nclasses 2 else nclasses Constants in decision function

randomstate0 tol1e05 verbose0
printregrcoef
1635 2691 4230 6047
printregrintercept
429
printregrpredict0 0 0 0
429
```
Methods
fitself X y sampleweight Fit the model according to the given training data
getparams self deep Get parameters for this estimator
predict self X Predict using the linear model
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfepsilon00 tol00001 C10 loss’epsiloninsensitive’ fitinterceptTrue inter
ceptscaling10 dualTrue verbose0 randomstateNone maxiter1000
fitselfXysampleweightNone
Fit the model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples in the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target vector relative to X

sampleweight arraylike shape nsamples optional Array of weights that are as
signed to individual samples If not provided then each sample is given unit weight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage

sionfunctionshape’ovr’ randomstateNone
NuSupport Vector Classification
Similar to SVC but uses a parameter to control the number of support vectors
The implementation is based on libsvm
Read more in the User Guide
Parameters
nufloat optional default05 An upper bound on the fraction of training errors and a lower
bound of the fraction of support vectors Should be in the interval 0 1
kernel string optional default’rbf’ Specifies the kernel type to be used in the algorithm
It must be one of ‘linear’ ‘poly’ ‘rbf’ ‘sigmoid’ ‘precomputed’ or a callable If none is
given ‘rbf’ will be used If a callable is given it is used to precompute the kernel matrix
degree int optional default3 Degree of the polynomial kernel function ‘poly’ Ignored
by all other kernels
gamma float optional default’auto’ Kernel coefficient for ‘rbf’ ‘poly’ and ‘sigmoid’
Current default is ‘auto’ which uses 1 nfeatures if gammascale is passed then it
uses 1 nfeatures Xvar as value of gamma The current default of gamma ‘auto’
will change to ‘scale’ in version 022 ‘autodeprecated’ a deprecated version of ‘auto’ is
used as a default indicating that no explicit value of gamma was passed
coef0 float optional default00 Independent term in kernel function It is only significant
in ‘poly’ and ‘sigmoid’
shrinking boolean optional defaultTrue Whether to use the shrinking heuristic
probability boolean optional defaultFalse Whether to enable probability estimates This
must be enabled prior to calling fit and will slow down that method
tolfloat optional default1e3 Tolerance for stopping criterion
cachesize float optional Specify the size of the kernel cache in MB
classweight dict ‘balanced’ optional Set the parameter C of class i to classweightiC
for SVC If not given all classes are supposed to have weight one The “balanced” mode
uses the values of y to automatically adjust weights inversely proportional to class frequen
cies asnsamples nclasses npbincounty
637sklearnsvm Support Vector Machines 2307

verbose bool default False Enable verbose output Note that this setting takes advantage of a perprocess runtime setting in libsvm that if enabled may not work properly in a multithreaded context
maxiter int optional default1 Hard limit on iterations within solver or 1 for no limit
decisionfunctionshape ‘ovo’ ‘ovr’ default’ovr’ Whether to return a onevsrest ‘ovr’ decision function of shape nsamples nclasses as all other classifiers or the original onevsone ‘ovo’ decision function of libsvm which has shape nsamples nclasses nclasses 1 2
Changed in version 019 decisionfunctionshape is ‘ovr’ by default
New in version 017 decisionfunctionshape’ovr’ is recommended
Changed in version 017 Deprecated decisionfunctionshape’ovo’ and None
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator used when shuffling the data for probability estimates If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number gen erator is the RandomState instance used by nprandom
Attributes
support arraylike shape nSV Indices of support vectors
supportvectors arraylike shape nSV nfeatures Support vectors
nsupport arraylike dtypeint32 shape nclass Number of support vectors for each class
dualcoef array shape nclass1 nSV Coefficients of the support vector in the decision function For multiclass coefficient for all 1vs1 classifiers The layout of the coefficients in the multiclass case is somewhat nontrivial See the section about multiclass classifica tion in the SVM section of the User Guide for details
coef array shape nclass nclass1 2 nfeatures Weights assigned to the features coefficients in the primal problem This is only available in the case of a linear kernel coef is readonly property derived from dualcoef andsupportvectors
intercept array shape nclass nclass1 2 Constants in decision function

ingTrue probabilityFalse tol0001 cachesize200 classweightNone ver
boseFalse maxiter1 decisionfunctionshape’ovr’ randomstateNone
decisionfunction selfX
Evaluates the decision function for the samples in X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Xarraylike shape nsamples nclasses nclasses1 2 Returns the decision func
tion of the sample for each class in the model If decisionfunctionshape’ovr’ the shape
is nsamples nclasses
Notes
If decisionfunctionshape’ovo’ the function values are proportional to the distance of the samples X to
the separating hyperplane If the exact distances are required divide the function values by the norm of
the weight vector coef See also this question for further details If decisionfunctionshape’ovr’
the decision function is a monotonic transformation of ovo decision function
fitselfXysampleweightNone
Fit the SVM model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features For ker
nel”precomputed” the expected shape of X is nsamples nsamples
yarraylike shape nsamples Target values class labels in classification real numbers
in regression

sampleweight arraylike shape nsamples Persample weights Rescale C per sample
Higher weights force the classifier to put more emphasis on these points
Returns
self object
Notes
If X and y are not Cordered and contiguous arrays of npfloat64 and X is not a scipysparsecsrmatrix X
andor y may be copied
If X is a dense array then the other methods will not support sparse matrices as input
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Perform classification on samples in X
For an oneclass model 1 or 1 is returned
Parameters
Xarraylike sparse matrix shape nsamples nfeatures For kernel”precomputed”
the expected shape of X is nsamplestest nsamplestrain
Returns
ypred array shape nsamples Class labels for samples in X
predictlogproba
Compute log probabilities of possible outcomes for samples in X
The model need to have probability information computed at training time fit with attribute
probability set to True
Parameters
Xarraylike shape nsamples nfeatures For kernel”precomputed” the expected
shape of X is nsamplestest nsamplestrain
Returns
Tarraylike shape nsamples nclasses Returns the logprobabilities of the sample for
each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
Notes
The probability model is created using cross validation so the results can be slightly different than those
obtained by predict Also it will produce meaningless results on very small datasets

predictproba

nel matrix from data matrices that matrix should be an array of shape nsamples
nsamples
degree int optional default3 Degree of the polynomial kernel function ‘poly’ Ignored
by all other kernels
gamma float optional default’auto’ Kernel coefficient for ‘rbf’ ‘poly’ and ‘sigmoid’
Current default is ‘auto’ which uses 1 nfeatures if gammascale is passed then it
uses 1 nfeatures Xvar as value of gamma The current default of gamma ‘auto’
will change to ‘scale’ in version 022 ‘autodeprecated’ a deprecated version of ‘auto’ is
used as a default indicating that no explicit value of gamma was passed
coef0 float optional default00 Independent term in kernel function It is only significant
in ‘poly’ and ‘sigmoid’
shrinking boolean optional defaultTrue Whether to use the shrinking heuristic
probability boolean optional defaultFalse Whether to enable probability estimates This
must be enabled prior to calling fit and will slow down that method
tolfloat optional default1e3 Tolerance for stopping criterion
cachesize float optional Specify the size of the kernel cache in MB
classweight dict ‘balanced’ optional Set the parameter C of class i to classweightiC
for SVC If not given all classes are supposed to have weight one The “balanced” mode
uses the values of y to automatically adjust weights inversely proportional to class frequen
cies in the input data as nsamples nclasses npbincounty
verbose bool default False Enable verbose output Note that this setting takes advantage
of a perprocess runtime setting in libsvm that if enabled may not work properly in a
multithreaded context
maxiter int optional default1 Hard limit on iterations within solver or 1 for no limit
decisionfunctionshape ‘ovo’ ‘ovr’ default’ovr’ Whether to return a onevsrest ‘ovr’
decision function of shape nsamples nclasses as all other classifiers or the original
onevsone ‘ovo’ decision function of libsvm which has shape nsamples nclasses
nclasses 1 2 However onevsone ‘ovo’ is always used as multiclass strategy
Changed in version 019 decisionfunctionshape is ‘ovr’ by default
New in version 017 decisionfunctionshape’ovr’ is recommended
Changed in version 017 Deprecated decisionfunctionshape’ovo’ and None
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator used when shuffling the data for probability estimates
If int randomstate is the seed used by the random number generator If RandomState
instance randomstate is the random number generator If None the random number gen
erator is the RandomState instance used by nprandom
Attributes
support arraylike shape nSV Indices of support vectors

supportvectors arraylike shape nSV nfeatures Support vectors
nsupport arraylike dtypeint32 shape nclass Number of support vectors for each
class
dualcoef array shape nclass1 nSV Coefficients of the support vector in the decision
function For multiclass coefficient for all 1vs1 classifiers The layout of the coefficients
in the multiclass case is somewhat nontrivial See the section about multiclass classifica
tion in the SVM section of the User Guide for details
coef array shape nclass nclass1 2 nfeatures Weights assigned to the features
coefficients in the primal problem This is only available in the case of a linear kernel
coef is a readonly property derived from dualcoef andsupportvectors
intercept array shape nclass nclass1 2 Constants in decision function
fitstatus int 0 if correctly fitted 1 otherwise will raise warning
probA array shape nclass nclass1 2
probB array shape nclass nclass1 2 If probabilityTrue the parameters
learned in Platt scaling to produce probability estimates from decision values If prob
abilityFalse an empty array Platt scaling uses the logistic function 1 1
expdecisionvalue probA probB whereprobA andprobB are
learned from the dataset R20c70293ef722 For more information on the multiclass case
and training procedure see section 8 of R20c70293ef721

Methods
decisionfunction self X Evaluates the decision function for the samples in X
fitself X y sampleweight Fit the SVM model according to the given training data
getparams self deep Get parameters for this estimator
predict self X Perform classification on samples in X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfC10 kernel’rbf’ degree3 gamma’autodeprecated’ coef000 shrink
ingTrue probabilityFalse tol0001 cachesize200 classweightNone ver
boseFalse maxiter1 decisionfunctionshape’ovr’ randomstateNone
decisionfunction selfX
Evaluates the decision function for the samples in X
Parameters
Xarraylike shape nsamples nfeatures
Returns
Xarraylike shape nsamples nclasses nclasses1 2 Returns the decision func
tion of the sample for each class in the model If decisionfunctionshape’ovr’ the shape
is nsamples nclasses
Notes
If decisionfunctionshape’ovo’ the function values are proportional to the distance of the samples X to
the separating hyperplane If the exact distances are required divide the function values by the norm of
the weight vector coef See also this question for further details If decisionfunctionshape’ovr’
the decision function is a monotonic transformation of ovo decision function
fitselfXysampleweightNone
Fit the SVM model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features For ker
nel”precomputed” the expected shape of X is nsamples nsamples
yarraylike shape nsamples Target values class labels in classification real numbers
in regression
sampleweight arraylike shape nsamples Persample weights Rescale C per sample
Higher weights force the classifier to put more emphasis on these points
Returns
self object
Notes
If X and y are not Cordered and contiguous arrays of npfloat64 and X is not a scipysparsecsrmatrix X
andor y may be copied

If X is a dense array then the other methods will not support sparse matrices as input
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Perform classification on samples in X
For an oneclass model 1 or 1 is returned
Parameters
Xarraylike sparse matrix shape nsamples nfeatures For kernel”precomputed”
the expected shape of X is nsamplestest nsamplestrain
Returns
ypred array shape nsamples Class labels for samples in X
predictlogproba
Compute log probabilities of possible outcomes for samples in X
The model need to have probability information computed at training time fit with attribute
probability set to True
Parameters
Xarraylike shape nsamples nfeatures For kernel”precomputed” the expected
shape of X is nsamplestest nsamplestrain
Returns
Tarraylike shape nsamples nclasses Returns the logprobabilities of the sample for
each class in the model The columns correspond to the classes in sorted order as they
appear in the attribute classes
Notes
The probability model is created using cross validation so the results can be slightly different than those
obtained by predict Also it will produce meaningless results on very small datasets
predictproba
Compute probabilities of possible outcomes for samples in X
The model need to have probability information computed at training time fit with attribute
probability set to True
Parameters
Xarraylike shape nsamples nfeatures For kernel”precomputed” the expected
shape of X is nsamplestest nsamplestrain
Returns

Tarraylike shape nsamples nclasses Returns the probability of the sample for each
class in the model The columns correspond to the classes in sorted order as they appear
in the attribute classes
Notes
The probability model is created using cross validation so the results can be slightly different than those
obtained by predict Also it will produce meaningless results on very small datasets
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnsvmSVC
•Multilabel classification
•Explicit feature map approximation for RBF kernels
•Faces recognition example using eigenfaces and SVMs
•Libsvm GUI
•Recognizing handwritten digits
•Plot classification probability
•Classifier comparison
•Concatenating multiple feature extraction methods
•Plot the decision boundaries of a VotingClassifier
•Crossvalidation on Digits Dataset Exercise
•SVM Exercise
•Recursive feature elimination

•Recursive feature elimination with crossvalidation
•Test with permutations the significance of a classification score
•Univariate Feature Selection
•Plotting Validation Curves
•Parameter estimation using grid search with crossvalidation
•Receiver Operating Characteristic ROC with cross validation
•Nested versus nonnested crossvalidation
•Confusion matrix
•Receiver Operating Characteristic ROC
•Plotting Learning Curves
•Feature discretization
•Decision boundary of label propagation versus SVM on the Iris dataset
•SVM Maximum margin separating hyperplane
•SVM with custom kernel
•SVM Weighted samples
•SVM Separating hyperplane for unbalanced classes
•SVMKernels
•SVMAnova SVM with univariate feature selection
•SVM Margins Example
•Plot different SVM classifiers in the iris dataset
•RBF SVM parameters

C10 epsilon01 shrinkingTrue cachesize200 verboseFalse
maxiter1
EpsilonSupport Vector Regression
The free parameters in the model are C and epsilon
The implementation is based on libsvm The fit time complexity is more than quadratic with the number of sam
ples which makes it hard to scale to datasets with more than a couple of 10000 samples For large datasets con
sider using sklearnlinearmodelLinearSVR orsklearnlinearmodelSGDRegressor
instead possibly after a sklearnkernelapproximationNystroem transformer
Read more in the User Guide
Parameters
kernel string optional default’rbf’ Specifies the kernel type to be used in the algorithm
It must be one of ‘linear’ ‘poly’ ‘rbf’ ‘sigmoid’ ‘precomputed’ or a callable If none is
given ‘rbf’ will be used If a callable is given it is used to precompute the kernel matrix
degree int optional default3 Degree of the polynomial kernel function ‘poly’ Ignored
by all other kernels

scikitlearn user guide Release 0213
gamma float optional default'auto' Kernel coefficient for 'rbf' 'poly' and 'sigmoid'
Current default is 'auto' which uses 1 nfeatures if gammascale is passed then it
uses 1 nfeatures Xvar as value of gamma The current default of gamma 'auto'
will change to 'scale' in version 022 'autodeprecated' a deprecated version of 'auto' is
used as a default indicating that no explicit value of gamma was passed
coef0 float optional default00 Independent term in kernel function It is only significant
in 'poly' and 'sigmoid'
tolfloat optional default1e3 Tolerance for stopping criterion
Cfloat optional default10 Penalty parameter C of the error term
epsilon float optional default01 Epsilon in the epsilonSVR model It specifies the
epsilontube within which no penalty is associated in the training loss function with points
predicted within a distance epsilon from the actual value
shrinking boolean optional defaultTrue Whether to use the shrinking heuristic
cachesize float optional Specify the size of the kernel cache in MB
verbose bool default False Enable verbose output Note that this setting takes advantage
of a perprocess runtime setting in libsvm that if enabled may not work properly in a
multithreaded context
maxiter int optional default1 Hard limit on iterations within solver or 1 for no limit
Attributes
support arraylike shape nSV Indices of support vectors
supportvectors arraylike shape nSV nfeatures Support vectors
dualcoef array shape 1 nSV Coefficients of the support vector in the decision func
tion
coef array shape 1 nfeatures Weights assigned to the features coefficients in the primal
problem This is only available in the case of a linear kernel
coef is readonly property derived from dualcoef andsupportvectors
intercept array shape 1 Constants in decision function

getparams self deep Get parameters for this estimator
predict self X Perform regression on samples in X
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfkernel'rbf' degree3 gamma'autodeprecated' coef000 tol0001 C10 ep
silon01 shrinkingTrue cachesize200 verboseFalse maxiter1
fitselfXysampleweightNone
Fit the SVM model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vectors where
nsamples is the number of samples and nfeatures is the number of features For ker
nel"precomputed" the expected shape of X is nsamples nsamples
yarraylike shape nsamples Target values class labels in classification real numbers
in regression
sampleweight arraylike shape nsamples Persample weights Rescale C per sample
Higher weights force the classifier to put more emphasis on these points
Returns
self object
Notes
If X and y are not Cordered and contiguous arrays of npfloat64 and X is not a scipysparsecsrmatrix X
andor y may be copied
If X is a dense array then the other methods will not support sparse matrices as input
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values

predictselfX
Perform regression on samples in X
For an oneclass model 1 inlier or 1 outlier is returned
Parameters
Xarraylike sparse matrix shape nsamples nfeatures For kernel”precomputed”
the expected shape of X is nsamplestest nsamplestrain
Returns
ypred array shape nsamples
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnsvmSVR
•Comparison of kernel ridge regression and SVR
•Prediction Latency

•Support Vector Regression SVR using linear and nonlinear kernels
svml1minc X y loss fitintercept Return the lowest bound for C such that for C in l1minC
infinity the model is guaranteed not to be empty
sklearnsvm l1minc
sklearnsvm l1minc Xyloss'squaredhinge' fitinterceptTrue interceptscaling10
Return the lowest bound for C such that for C in l1minC infinity the model is guaranteed not
to be empty This applies to l1 penalized classifiers such as LinearSVC with penalty'l1' and lin
earmodelLogisticRegression with penalty'l1'
This value is valid if classweight parameter in fit is not set
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Training vector where
nsamples in the number of samples and nfeatures is the number of features
yarray shape nsamples Target vector relative to X
loss 'squaredhinge' 'log' default 'squaredhinge' Specifies the loss function With
'squaredhinge' it is the squared hinge loss aka L2 loss With 'log' it is the loss of
logistic regression models
fitintercept bool default True Specifies if the intercept should be fitted by the model It
must match the fit method parameter
interceptscaling float default 1 when fitintercept is True instance vector x becomes x
interceptscaling ie a "synthetic" feature with constant value equals to interceptscaling
is appended to the instance vector It must match the fit method parameter
Returns
l1minc float minimum value for C
Examples using sklearnsvml1minc
•Regularization path of L1 Logistic Regression

coef0 float Independent parameter in polysigmoid kernel
Returns
decvalues array predicted values

scikitlearn user guide Release 0213
sklearnsvmlibsvm predictproba
sklearnsvmlibsvm predictproba
Predict probabilities
svmmodel stores all parameters needed to predict a given value
For speed all real work is done at the C level in function copypredict libsvmhelperc
We have to reconstruct model and parameters to make sure we stay in sync with the python object
See sklearnsvmpredict for a complete list of parameters
Parameters
Xarraylike dtypefloat
kernel ‘linear’ ‘rbf’ ‘poly’ ‘sigmoid’ ‘precomputed’
Returns
decvalues array predicted values
638sklearntree Decision Trees
Thesklearntree module includes decision treebased models for classification and regression
User guide See the Decision Trees section for further details
treeDecisionTreeClassifier criterion A decision tree classifier
treeDecisionTreeRegressor criterion A decision tree regressor
treeExtraTreeClassifier criterion An extremely randomized tree classifier
treeExtraTreeRegressor criterion An extremely randomized tree regressor
6381sklearntree DecisionTreeClassifier
classsklearntree DecisionTreeClassifier criterion’gini’ splitter’best’ maxdepthNone
minsamplessplit2 minsamplesleaf1
minweightfractionleaf00
maxfeaturesNone ran
domstateNone maxleafnodesNone
minimpuritydecrease00
minimpuritysplitNone classweightNone
presortFalse
A decision tree classifier
Read more in the User Guide
Parameters
criterion string optional default”gini” The function to measure the quality of a split Sup
ported criteria are “gini” for the Gini impurity and “entropy” for the information gain
splitter string optional default”best” The strategy used to choose the split at each node
Supported strategies are “best” to choose the best split and “random” to choose the best
random split
maxdepth int or None optional defaultNone The maximum depth of the tree If None
638sklearntree Decision Trees 2331

then nodes are expanded until all leaves are pure or until all leaves contain less than
minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided
maxfeatures int float string or None optional defaultNone The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturessqrtnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
maxleafnodes int or None optional defaultNone Grow a tree with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity

whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
classweight dict list of dicts “balanced” or None defaultNone Weights associated with
classes in the form classlabel weight If not given all classes are supposed
to have weight one For multioutput problems a list of dicts can be provided in the same
order as the columns of y
Note that for multioutput including multilabel weights should be defined for each class of
every column in its own dict For example for fourclass multilabel classification weights
should be 0 1 1 1 0 1 1 5 0 1 1 1 0 1 1 1 instead of 11 25
31 41
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
For multioutput the weights of each column of y will be multiplied
Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified
presort bool optional defaultFalse Whether to presort the data to speed up the finding of
best splits in fitting For the default settings of a decision tree on large datasets setting
this to true may slow down the training process When using either a smaller dataset or a
restricted depth this may speed up the training
Attributes
classes array of shape nclasses or a list of such arrays The classes labels single output
problem or a list of arrays of class labels multioutput problem
featureimportances array of shape nfeatures Return the feature importances
maxfeatures int The inferred value of maxfeatures
nclasses int or list The number of classes for single output problems or a list containing
the number of classes for each output for multioutput problems
nfeatures int The number of features when fit is performed
noutputs int The number of outputs when fit is performed
tree Tree object The underlying Tree object Please refer to helpsklearntree
treeTree for attributes of Tree object and Understanding the decision tree structure
for basic usage of these attributes
See also
DecisionTreeRegressor

Notes
The default values for the parameters controlling the size of the trees eg maxdepth
minsamplesleaf etc lead to fully grown and unpruned trees which can potentially be very large on
some data sets To reduce memory consumption the complexity and size of the trees should be controlled by
setting those parameter values
The features are always randomly permuted at each split Therefore the best found split may vary even with
the same training data and maxfeaturesnfeatures if the improvement of the criterion is identical for
several splits enumerated during the search of the best split To obtain a deterministic behaviour during fitting
randomstate has to be fixed

applyselfXcheckinputTrue
Returns the index of the leaf that each sample is predicted as
New in version 017
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Returns
Xleaves arraylike shape nsamples For each datapoint x in X return the index of
the leaf x ends up in Leaves are numbered within 0 selftreenodecount
possibly with gaps in the numbering
decisionpath selfXcheckinputTrue
Return the decision path in the tree
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix
where non zero elements indicates that the samples goes through the nodes
featureimportances
Return the feature importances
The importance of a feature is computed as the normalized total reduction of the criterion brought by that
feature It is also known as the Gini importance
Returns
featureimportances array shape nfeatures
fitselfXysampleweightNone checkinputTrue XidxsortedNone
Build a decision tree classifier from the training set X y
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The training input samples
Internally it will be converted to dtypenpfloat32 and if a sparse matrix is provided
to a sparsecscmatrix
yarraylike shape nsamples or nsamples noutputs The target values class la
bels as integers or strings
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or nega
tive weight are ignored while searching for a split in each node Splits are also ignored if
they would result in any single class carrying a negative weight in either child node
638sklearntree Decision Trees 2335

checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Xidxsorted arraylike shape nsamples nfeatures optional The indexes of the
sorted training input samples If many tree are grown on the same dataset this allows the
ordering to be cached between trees If None the data will be sorted here Don’t use this
parameter unless you know what to do
Returns
self object
getdepth self
Returns the depth of the decision tree
The depth of a tree is the maximum distance between the root and any leaf
getnleaves self
Returns the number of leaves of the decision tree
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfXcheckinputTrue
Predict class or regression value for X
For a classification model the predicted class for each sample in X is returned For a regression model
the predicted value based on X is returned
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Returns
yarray of shape nsamples or nsamples noutputs The predicted classes or the
predict values
predictlogproba selfX
Predict class logprobabilities of the input samples X
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns

parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs
 1 The class logprobabilities of the input samples The order of the classes corresponds
to that in the attribute classes
predictproba selfXcheckinputTrue
Predict class probabilities of the input samples X
The predicted class probability is the fraction of samples of the same class in a leaf
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use this parameter
unless you know what you do
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput bool Run checkarray on X
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs
 1 The class probabilities of the input samples The order of the classes corresponds to
that in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearntreeDecisionTreeClassifier
•Classifier comparison
•Plot the decision boundaries of a VotingClassifier
•Twoclass AdaBoost
•Multiclass AdaBoosted Decision Trees

•Discrete versus Real AdaBoost
•Plot the decision surfaces of ensembles of trees on the iris dataset
•Demonstration of multimetric evaluation on crossvalscore and GridSearchCV
•Plot the decision surface of a decision tree on the iris dataset
•Understanding the decision tree structure
6382sklearntree DecisionTreeRegressor
classsklearntree DecisionTreeRegressor criterion'mse' splitter'best' maxdepthNone
minsamplessplit2 minsamplesleaf1
minweightfractionleaf00 maxfeaturesNone
randomstateNone maxleafnodesNone
minimpuritydecrease00
minimpuritysplitNone presortFalse
A decision tree regressor
Read more in the User Guide
Parameters
criterion string optional default"mse" The function to measure the quality of a split Sup
ported criteria are "mse" for the mean squared error which is equal to variance reduction as
feature selection criterion and minimizes the L2 loss using the mean of each terminal node
"friedmanmse" which uses mean squared error with Friedman's improvement score for
potential splits and "mae" for the mean absolute error which minimizes the L1 loss using
the median of each terminal node
New in version 018 Mean Absolute Error MAE criterion
splitter string optional default"best" The strategy used to choose the split at each node
Supported strategies are "best" to choose the best split and "random" to choose the best
random split
maxdepth int or None optional defaultNone The maximum depth of the tree If None
then nodes are expanded until all leaves are pure or until all leaves contain less than
minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions

minweightfractionleaf float optional default0 The minimum weighted fraction of the sum total of weights of all the input samples required to be at a leaf node Samples have equal weight when sampleweight is not provided
maxfeatures int float string or None optional defaultNone The number of features to consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures nfeatures features are considered at each split
• If “auto” then maxfeaturesnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples is found even if it requires to effectively inspect more than maxfeatures features
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
maxleafnodes int or None optional defaultNone Grow a tree with maxleafnodes in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node NtL is the number of samples in the left child and NtR is the number of samples in the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of minimpuritydecrease in 019 The default value of minimpuritysplit will change from 1e7 to 0 in 023 and it will be removed in 025 Use minimpuritydecrease instead
presort bool optional defaultFalse Whether to presort the data to speed up the finding of best splits in fitting For the default settings of a decision tree on large datasets setting this to true may slow down the training process When using either a smaller dataset or a restricted depth this may speed up the training
Attributes
featureimportances array of shape nfeatures Return the feature importances

maxfeatures int The inferred value of maxfeatures
nfeatures int The number of features when fit is performed
noutputs int The number of outputs when fit is performed
tree Tree object The underlying Tree object Please refer to helpsklearntree
treeTree for attributes of Tree object and Understanding the decision tree structure
for basic usage of these attributes
See also
DecisionTreeClassifier
Notes
The default values for the parameters controlling the size of the trees eg maxdepth
minsamplesleaf etc lead to fully grown and unpruned trees which can potentially be very large on
some data sets To reduce memory consumption the complexity and size of the trees should be controlled by
setting those parameter values
The features are always randomly permuted at each split Therefore the best found split may vary even with
the same training data and maxfeaturesnfeatures if the improvement of the criterion is identical for
several splits enumerated during the search of the best split To obtain a deterministic behaviour during fitting
randomstate has to be fixed

Methods
apply self X checkinput Returns the index of the leaf that each sample is pre
dicted as
decisionpath self X checkinput Return the decision path in the tree
fitself X y sampleweight Build a decision tree regressor from the training set X
y
getdepth self Returns the depth of the decision tree
Continued on next page

Table 6284 – continued from previous page
getnleaves self Returns the number of leaves of the decision tree
getparams self deep Get parameters for this estimator
predict self X checkinput Predict class or regression value for X
score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfcriterion'mse' splitter'best' maxdepthNone minsamplessplit2
minsamplesleaf1 minweightfractionleaf00 maxfeaturesNone
randomstateNone maxleafnodesNone minimpuritydecrease00
minimpuritysplitNone presortFalse
applyselfXcheckinputTrue
Returns the index of the leaf that each sample is predicted as
New in version 017
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don't use
this parameter unless you know what you do
Returns
Xleaves arraylike shape nsamples For each datapoint x in X return the index of
the leaf x ends up in Leaves are numbered within 0 selftreenodecount
possibly with gaps in the numbering
decisionpath selfXcheckinputTrue
Return the decision path in the tree
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don't use
this parameter unless you know what you do
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix
where non zero elements indicates that the samples goes through the nodes
featureimportances
Return the feature importances
The importance of a feature is computed as the normalized total reduction of the criterion brought by that
feature It is also known as the Gini importance
Returns
featureimportances array shape nfeatures

fitselfXysampleweightNone checkinputTrue XidxsortedNone
Build a decision tree regressor from the training set X y
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The training input samples
Internally it will be converted to dtypenpfloat32 and if a sparse matrix is provided
to a sparsecscmatrix
yarraylike shape nsamples or nsamples noutputs The target values real num
bers Usedtypenpfloat64 andorderC for maximum efficiency
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or nega
tive weight are ignored while searching for a split in each node
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Xidxsorted arraylike shape nsamples nfeatures optional The indexes of the
sorted training input samples If many tree are grown on the same dataset this allows the
ordering to be cached between trees If None the data will be sorted here Don’t use this
parameter unless you know what to do
Returns
self object
getdepth self
Returns the depth of the decision tree
The depth of a tree is the maximum distance between the root and any leaf
getnleaves self
Returns the number of leaves of the decision tree
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfXcheckinputTrue
Predict class or regression value for X
For a classification model the predicted class for each sample in X is returned For a regression model
the predicted value based on X is returned
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Returns

yarray of shape nsamples or nsamples noutputs The predicted classes or the
predict values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearntreeDecisionTreeRegressor
•Decision Tree Regression with AdaBoost
•Single estimator versus bagging biasvariance decomposition
•Imputing missing values with variants of IterativeImputer
•Using KBinsDiscretizer to discretize continuous features
•Decision Tree Regression
•Multioutput Decision Tree Regression

classsklearntree ExtraTreeClassifier criterion’gini’ splitter’random’
maxdepthNone minsamplessplit2
minsamplesleaf1 minweightfractionleaf00
maxfeatures’auto’ randomstateNone
maxleafnodesNone minimpuritydecrease00
minimpuritysplitNone classweightNone
An extremely randomized tree classifier
Extratrees differ from classic decision trees in the way they are built When looking for the best split to separate the samples of a node into two groups random splits are drawn for each of the maxfeatures randomly selected features and the best split among those is chosen When maxfeatures is set 1 this amounts to building a totally random decision tree
Warning Extratrees should only be used within ensemble methods
Read more in the User Guide
Parameters
criterion string optional default”gini” The function to measure the quality of a split Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain
splitter string optional default”random” The strategy used to choose the split at each node Supported strategies are “best” to choose the best split and “random” to choose the best random split
maxdepth int or None optional defaultNone The maximum depth of the tree If None then nodes are expanded until all leaves are pure or until all leaves contain less than minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required to be at a leaf node A split point at any depth will only be considered if it leaves at least minsamplesleaf training samples in each of the left and right branches This may have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the sum total of weights of all the input samples required to be at a leaf node Samples have equal weight when sampleweight is not provided
maxfeatures int float string or None optional default”auto” The number of features to consider when looking for the best split
• If int then consider maxfeatures features at each split

• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturessqrtnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
maxleafnodes int or None optional defaultNone Grow a tree with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
classweight dict list of dicts “balanced” or None defaultNone Weights associated with
classes in the form classlabel weight If not given all classes are supposed
to have weight one For multioutput problems a list of dicts can be provided in the same
order as the columns of y
Note that for multioutput including multilabel weights should be defined for each class of
every column in its own dict For example for fourclass multilabel classification weights
should be 0 1 1 1 0 1 1 5 0 1 1 1 0 1 1 1 instead of 11 25
31 41
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
For multioutput the weights of each column of y will be multiplied

Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified

minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
maxleafnodes int or None optional defaultNone Grow a tree with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
Attributes
featureimportances Return the feature importances
See also
ExtraTreeClassifier sklearnensembleExtraTreesClassifier
sklearnensembleExtraTreesRegressor
Notes
The default values for the parameters controlling the size of the trees eg maxdepth
minsamplesleaf etc lead to fully grown and unpruned trees which can potentially be very large on
some data sets To reduce memory consumption the complexity and size of the trees should be controlled by
setting those parameter values
References
R4939d63d5a491
Methods

apply self X checkinput Returns the index of the leaf that each sample is pre dicted as
decisionpath self X checkinput Return the decision path in the tree
fitself X y sampleweight Build a decision tree regressor from the training set X y
getdepth self Returns the depth of the decision tree
getnleaves self Returns the number of leaves of the decision tree
getparams self deep Get parameters for this estimator
predict self X checkinput Predict class or regression value for X
score self X y sampleweight Returns the coefficient of determination R2 of the pre diction
setparams self params Set the parameters of this estimator
init selfcriterion'mse' splitter'random' maxdepthNone minsamplessplit2 minsamplesleaf1 minweightfractionleaf00 maxfeatures'auto' randomstateNone minimpuritydecrease00 minimpuritysplitNone maxleafnodesNone
applyselfXcheckinputTrue
Returns the index of the leaf that each sample is predicted as
New in version 017
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don't use this parameter unless you know what you do
Returns
Xleaves arraylike shape nsamples For each datapoint x in X return the index of the leaf x ends up in Leaves are numbered within 0 selftreenodecount possibly with gaps in the numbering
decisionpath selfXcheckinputTrue
Return the decision path in the tree
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don't use this parameter unless you know what you do
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes
featureimportances
Return the feature importances

The importance of a feature is computed as the normalized total reduction of the criterion brought by that feature It is also known as the Gini importance
Returns
featureimportances array shape nfeatures
fitselfXysampleweightNone checkinputTrue XidxsortedNone
Build a decision tree regressor from the training set X y
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The training input samples Internally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to a sparsecscmatrix
yarraylike shape nsamples or nsamples noutputs The target values real numbers Usedtypenpfloat64 andorderC for maximum efficiency
sampleweight arraylike shape nsamples or None Sample weights If None then samples are equally weighted Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use this parameter unless you know what you do
Xidxsorted arraylike shape nsamples nfeatures optional The indexes of the sorted training input samples If many tree are grown on the same dataset this allows the ordering to be cached between trees If None the data will be sorted here Don’t use this parameter unless you know what to do
Returns
self object
getdepth self
Returns the depth of the decision tree
The depth of a tree is the maximum distance between the root and any leaf
getnleaves self
Returns the number of leaves of the decision tree
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfXcheckinputTrue
Predict class or regression value for X
For a classification model the predicted class for each sample in X is returned For a regression model the predicted value based on X is returned
Parameters

Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
checkinput boolean defaultTrue Allow to bypass several input checking Don’t use
this parameter unless you know what you do
Returns
yarray of shape nsamples or nsamples noutputs The predicted classes or the
predict values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
treeexportgraphviz decisiontree Export a decision tree in DOT format
treeplottree decisiontree maxdepth Plot a decision tree
treeexporttext decisiontree Build a text report showing the rules of a decision tree

scikitlearn user guide Release 0213

sklearntree exportgraphviz decisiontree outfileNone maxdepthNone fea
turenamesNone classnamesNone label'all' filledFalse
leavesparallelFalse impurityTrue nodeidsFalse
proportionFalse rotateFalse roundedFalse spe
cialcharactersFalse precision3
Export a decision tree in DOT format
This function generates a GraphViz representation of the decision tree which is then written into outfile
Once exported graphical renderings can be generated using for example
 dot Tps treedot o treeps PostScript format
 dot Tpng treedot o treepng PNG format
The sample counts that are shown are weighted with any sampleweights that might be present
Read more in the User Guide
Parameters
decisiontree decision tree classifier The decision tree to be exported to GraphViz
outfile file object or string optional defaultNone Handle or name of the output file If
None the result is returned as a string
Changed in version 020 Default of outfile changed from "treedot" to None
maxdepth int optional defaultNone The maximum depth of the representation If None
the tree is fully generated
featurenames list of strings optional defaultNone Names of each of the features
classnames list of strings bool or None optional defaultNone Names of each of the target
classes in ascending numerical order Only relevant for classification and not supported for
multioutput If True shows a symbolic representation of the class name
label 'all' 'root' 'none' optional default'all' Whether to show informative labels for
impurity etc Options include 'all' to show at every node 'root' to show only at the top root
node or 'none' to not show at any node
filled bool optional defaultFalse When set to True paint nodes to indicate majority class
for classification extremity of values for regression or purity of node for multioutput
leavesparallel bool optional defaultFalse When set to True draw all leaf nodes at the
bottom of the tree
impurity bool optional defaultTrue When set to True show the impurity at each node
nodeids bool optional defaultFalse When set to True show the ID number on each
node
proportion bool optional defaultFalse When set to True change the display of 'values'
andor 'samples' to be proportions and percentages respectively
rotate bool optional defaultFalse When set to True orient tree left to right rather than
topdown
rounded bool optional defaultFalse When set to True draw node boxes with rounded
corners and use Helvetica fonts instead of TimesRoman
specialcharacters bool optional defaultFalse When set to False ignore special char
acters for PostScript compatibility
638sklearntree Decision Trees 2355

precision int optional default3 Number of digits of precision for floating point in the val
ues of impurity threshold and value attributes of each node
Returns
dotdata string String representation of the input tree in GraphViz dot format Only returned
ifoutfile is None
New in version 018
Examples
```
 from sklearndatasets import loadiris
 from sklearn import tree
clf  treeDecisionTreeClassifier
iris  loadiris
clf  clffitirisdata iristarget
treeexportgraphvizclf
digraph Tree
6386sklearntree plottree
sklearntree plottree decisiontree maxdepthNone featurenamesNone classnamesNone
label'all' filledFalse impurityTrue nodeidsFalse propor
tionFalse rotateFalse roundedFalse precision3 axNone font
sizeNone
```
Plot a decision tree
The sample counts that are shown are weighted with any sampleweights that might be present This function
requires matplotlib and works best with matplotlib 15
The visualization is fit automatically to the size of the axis Use the figsize ordpi arguments of plt
figure to control the size of the rendering
Read more in the User Guide
New in version 021
Parameters
decisiontree decision tree regressor or classifier The decision tree to be exported to
GraphViz
maxdepth int optional defaultNone The maximum depth of the representation If None
the tree is fully generated
featurenames list of strings optional defaultNone Names of each of the features
classnames list of strings bool or None optional defaultNone Names of each of the target
classes in ascending numerical order Only relevant for classification and not supported for
multioutput If True shows a symbolic representation of the class name
label 'all' 'root' 'none' optional default'all' Whether to show informative labels for
impurity etc Options include 'all' to show at every node 'root' to show only at the top root
node or 'none' to not show at any node

filled bool optional defaultFalse When set to True paint nodes to indicate majority class
for classification extremity of values for regression or purity of node for multioutput
impurity bool optional defaultTrue When set to True show the impurity at each node
nodeids bool optional defaultFalse When set to True show the ID number on each
node
proportion bool optional defaultFalse When set to True change the display of ‘values’
andor ‘samples’ to be proportions and percentages respectively
rotate bool optional defaultFalse When set to True orient tree left to right rather than
topdown
rounded bool optional defaultFalse When set to True draw node boxes with rounded
corners and use Helvetica fonts instead of TimesRoman
precision int optional default3 Number of digits of precision for floating point in the val
ues of impurity threshold and value attributes of each node
axmatplotlib axis optional defaultNone Axes to plot to If None use current axis Any
previous content is cleared
fontsize int optional defaultNone Size of text font If None determined automatically to
fit figure
Returns
annotations list of artists List containing the artists for the annotation boxes making up the
tree
Examples
 from sklearndatasets import loadiris
 from sklearn import tree
clf treeDecisionTreeClassifierrandomstate0
iris loadiris
clf clffitirisdata iristarget

6387sklearntree exporttext
sklearntree exporttext decisiontree featurenamesNone maxdepth10 spacing3 deci
mals2 showweightsFalse
Build a text report showing the rules of a decision tree
Note that backwards compatibility may not be supported
Parameters

scikitlearn user guide Release 0213
decisiontree object The decision tree estimator to be exported It can be an instance of
DecisionTreeClassifier or DecisionTreeRegressor
featurenames list optional defaultNone A list of length nfeatures containing the feature
names If None generic names will be used “feature0” “feature1”
maxdepth int optional default10 Only the first maxdepth levels of the tree are exported
Truncated branches will be marked with “ ”
spacing int optional default3 Number of spaces between edges The higher it is the wider
the result
decimals int optional default2 Number of decimal digits to display
showweights bool optional defaultFalse If true the classification weights will be exported
on each leaf The classification weights are the number of samples each class
Returns
report string Text summary of all the rules in the decision tree
Examples
```
 from sklearndatasets import loadiris
 from sklearntree import DecisionTreeClassifier
 from sklearntreeexport import exporttext
iris  loadiris

639sklearnutils Utilities
Thesklearnutils module includes various utilities
Developer guide See the Utilities for Developers page for further details
utilsarrayfuncscholeskydelete L
goout
utilsarrayfuncsminpos Find the minimum value of an array over positive values
utilsasfloatarray X copy forceallfinite Converts an arraylike to an array of floats
utilsassertallfinite X allownan Throw a ValueError if X contains NaN or infinity
utilscheckXy X y acceptsparse Input validation for standard estimators
Continued on next page

Table 6288 – continued from previous page
utilscheckarray array acceptsparse Input validation on an array list sparse matrix or similar
utilscheckscalar x name targettype Validate scalar parameters type and value
utilscheckconsistentlength arrays Check that all arrays have consistent first dimensions
utilscheckrandomstate seed Turn seed into a nprandomRandomState instance
utilsclassweight
computeclassweight Estimate class weights for unbalanced datasets
utilsclassweight
computesampleweight Estimate sample weights by class for unbalanced datasets
utilsdeprecated extra Decorator to mark a function or class as deprecated
utilsestimatorchecks
checkestimator EstimatorCheck if estimator adheres to scikitlearn conventions
utilsextmathsafesparsedot a b Dot product that handle the sparse matrix case correctly
utilsextmathrandomizedrangefinder A
Computes an orthonormal matrix whose range approxi
mates the range of A
utilsextmathrandomizedsvd M
ncomponentsComputes a truncated randomized SVD
utilsextmathfastlogdet A Compute logdetA for A symmetric
utilsextmathdensity w kwargs Compute density of a sparse vector
utilsextmathweightedmode a w axis Returns an array of the weighted modal most common
value in a
utilsgenevenslices n npacks nsamples Generator to create npacks slices going up to n
utilsgraphsinglesourceshortestpathlength Return the shortest path length from source to all reachable
nodes
utilsgraphshortestpath
graphshortestpath Perform a shortestpath graph search on a positive directed
or undirected graph
utilsindexable iterables Make arrays indexable for crossvalidation
utilsmetaestimators
ifdelegatehasmethod Create a decorator for methods that are delegated to a sub
estimator
utilsmulticlasstypeoftarget y Determine the type of data indicated by the target
utilsmulticlassismultilabel y Check if yis in a multilabel format
utilsmulticlassuniquelabels ys Extract an ordered array of unique labels
utilsmurmurhash332 Compute the 32bit murmurhash3 of key at seed
utilsresample arrays options Resample arrays or sparse matrices in a consistent way
utilssafeindexing X indices Return items or rows from X using indices
utilssafemask X mask Return a mask which is safe to use on X
utilssafesqr X copy Element wise squaring of arraylikes and sparse matrices
utilsshuffle arrays options Shuffle arrays or sparse matrices in a consistent way
utilssparsefuncs
incrmeanvarianceaxis X Compute incremental mean and variance along an axix on
a CSR or CSC matrix
utilssparsefuncs
inplacecolumnscale X scaleInplace column scaling of a CSCCSR matrix
utilssparsefuncsinplacerowscale X
scaleInplace row scaling of a CSR or CSC matrix
utilssparsefuncsinplaceswaprow X m
nSwaps two rows of a CSCCSR matrix inplace
utilssparsefuncs
inplaceswapcolumn X m nSwaps two columns of a CSCCSR matrix inplace
utilssparsefuncsmeanvarianceaxis X
axisCompute mean and variance along an axix on a CSR or
CSC matrix
utilssparsefuncs
inplacecsrcolumnscale X Inplace column scaling of a CSR matrix

utilstestingassertraisemessage Helper function to test the message raised in an exception
utilstestingallestimators Get a list of all estimators from sklearn
6391sklearnutils arrayfuncscholeskydelete
6392sklearnutilsarrayfuncs minpos
sklearnutilsarrayfuncs minpos
Find the minimum value of an array over positive values
Returns a huge value if none of the values are positive
6393sklearnutils asfloatarray
sklearnutils asfloatarray XcopyTrue forceallfiniteTrue
Converts an arraylike to an array of floats
The new dtype will be npfloat32 or npfloat64 depending on the original type The function can create a copy
or modify the argument depending on the argument copy
Parameters
Xarraylike sparse matrix
copy bool optional If True a copy of X will be created If False a copy may still be returned
if X's dtype is not a floating point type
forceallfinite boolean or 'allownan' defaultTrue Whether to raise an error on npinf
and npnan in X The possibilities are
• True Force all values of X to be finite
• False accept both npinf and npnan in X
• 'allownan' accept only npnan values in X Values cannot be infinite
New in version 020 forceallfinite accepts the string allownan
Returns

XT array sparse matrix An array of type npfloat
6394sklearnutils assertallfinite
sklearnutils assertallfinite XallownanFalse
Throw a ValueError if X contains NaN or infinity
Parameters
Xarray or sparse matrix
allownan bool
6395sklearnutils checkXy
sklearnutils checkXy XyacceptsparseFalse acceptlargesparseTrue dtype'numeric'
orderNone copyFalse forceallfiniteTrue ensure2dTrue
allowndFalse multioutputFalse ensureminsamples1 en
sureminfeatures1 ynumericFalse warnondtypeNone estima
torNone
Input validation for standard estimators
Checks X and y for consistent length enforces X to be 2D and y 1D By default X is checked to be nonempty
and containing only finite values Standard input checks are also applied to y such as checking that y does not
have npnan or npinf targets For multilabel y set multioutputTrue to allow 2D and sparse y If the dtype of
X is object attempt converting to float raising on failure
Parameters
Xndarray list or sparse matrix Input data
yndarray list or sparse matrix Labels
acceptsparse string boolean or list of string defaultFalse Strings representing allowed
sparse matrix formats such as 'csc' 'csr' etc If the input is sparse but not in the allowed
format it will be converted to the first listed format True allows the input to be any format
False means that a sparse matrix input will raise an error
acceptlargesparse bool defaultTrue If a CSR CSC COO or BSR sparse matrix is sup
plied and accepted by acceptsparse acceptlargesparse will cause it to be accepted only
if its indices are stored with a 32bit dtype
New in version 020
dtype string type list of types or None default"numeric" Data type of result If None the
dtype of the input is preserved If "numeric" dtype is preserved unless arraydtype is object
If dtype is a list of types conversion on the first type is only performed if the dtype of the
input is not in the list
order 'F' 'C' or None defaultNone Whether an array will be forced to be fortran or cstyle
copy boolean defaultFalse Whether a forced copy will be triggered If copyFalse a copy
might be triggered by a conversion
forceallfinite boolean or 'allownan' defaultTrue Whether to raise an error on npinf
and npnan in X This parameter does not influence whether y can have npinf or npnan
values The possibilities are
• True Force all values of X to be finite

• False accept both npinf and npnan in X
• ‘allownan’ accept only npnan values in X Values cannot be infinite
New in version 020 forceallfinite accepts the string allownan
ensure2d boolean defaultTrue Whether to raise a value error if X is not 2D
allownd boolean defaultFalse Whether to allow Xndim 2
multioutput boolean defaultFalse Whether to allow 2D y array or sparse matrix
If false y will be validated as a vector y cannot have npnan or npinf values if
multioutputTrue
ensureminsamples int default1 Make sure that X has a minimum number of samples in
its first axis rows for a 2D array
ensureminfeatures int default1 Make sure that the 2D array has some minimum number
of features columns The default value of 1 rejects empty datasets This check is only
enforced when X has effectively 2 dimensions or is originally 1D and ensure2d is True
Setting to 0 disables this check
ynumeric boolean defaultFalse Whether to ensure that y has a numeric type If dtype of
y is object it is converted to float64 Should only be used for regression algorithms
warnondtype boolean or None optional defaultNone Raise DataConversionWarning if
the dtype of the input data structure does not match the requested dtype causing a memory
copy
Deprecated since version 021 warnondtype is deprecated in version 021 and will be
removed in 023
estimator str or estimator instance defaultNone If passed include the name of the estimator
in warning messages
Returns
Xconverted object The converted and validated X
yconverted object The converted and validated y
6396sklearnutils checkarray
sklearnutils checkarray array acceptsparseFalse acceptlargesparseTrue
dtype’numeric’ orderNone copyFalse forceallfiniteTrue
ensure2dTrue allowndFalse ensureminsamples1 en
sureminfeatures1 warnondtypeNone estimatorNone
Input validation on an array list sparse matrix or similar
By default the input is checked to be a nonempty 2D array containing only finite values If the dtype of the
array is object attempt converting to float raising on failure
Parameters
array object Input object to check convert
acceptsparse string boolean or listtuple of strings defaultFalse Strings representing
allowed sparse matrix formats such as ‘csc’ ‘csr’ etc If the input is sparse but not in the
allowed format it will be converted to the first listed format True allows the input to be any
format False means that a sparse matrix input will raise an error

acceptlargesparse bool defaultTrue If a CSR CSC COO or BSR sparse matrix is sup
plied and accepted by acceptsparse acceptlargesparseFalse will cause it to be accepted
only if its indices are stored with a 32bit dtype
New in version 020
dtype string type list of types or None default”numeric” Data type of result If None the
dtype of the input is preserved If “numeric” dtype is preserved unless arraydtype is object
If dtype is a list of types conversion on the first type is only performed if the dtype of the
input is not in the list
order ‘F’ ‘C’ or None defaultNone Whether an array will be forced to be fortran or cstyle
When order is None default then if copyFalse nothing is ensured about the memory
layout of the output array otherwise copyTrue the memory layout of the returned array
is kept as close as possible to the original array
copy boolean defaultFalse Whether a forced copy will be triggered If copyFalse a copy
might be triggered by a conversion
forceallfinite boolean or ‘allownan’ defaultTrue Whether to raise an error on npinf
and npnan in array The possibilities are
• True Force all values of array to be finite
• False accept both npinf and npnan in array
• ‘allownan’ accept only npnan values in array Values cannot be infinite
For object dtyped data only npnan is checked and not npinf
New in version 020 forceallfinite accepts the string allownan
ensure2d boolean defaultTrue Whether to raise a value error if array is not 2D
allownd boolean defaultFalse Whether to allow arrayndim 2
ensureminsamples int default1 Make sure that the array has a minimum number of
samples in its first axis rows for a 2D array Setting to 0 disables this check
ensureminfeatures int default1 Make sure that the 2D array has some minimum number
of features columns The default value of 1 rejects empty datasets This check is only en
forced when the input data has effectively 2 dimensions or is originally 1D and ensure2d
is True Setting to 0 disables this check
warnondtype boolean or None optional defaultNone Raise DataConversionWarning if
the dtype of the input data structure does not match the requested dtype causing a memory
copy
Deprecated since version 021 warnondtype is deprecated in version 021 and will be
removed in 023
estimator str or estimator instance defaultNone If passed include the name of the estimator
in warning messages
Returns
arrayconverted object The converted and validated array
6397sklearnutils checkscalar
sklearnutils checkscalar xname targettype minvalNone maxvalNone
Validate scalar parameters type and value
639sklearnutils Utilities 2363

Parameters
xobject The scalar parameter to validate
name str The name of the parameter to be printed in error messages
targettype type or tuple Acceptable data types for the parameter
minval float or int optional defaultNone The minimum valid value the parameter can
take If None default it is implied that the parameter does not have a lower bound
maxval float or int optional defaultNone The maximum valid value the parameter can
take If None default it is implied that the parameter does not have an upper bound
Raises
TypeError If the parameter’s type does not match the desired type
ValueError If the parameter’s value violates the given bounds
6398sklearnutils checkconsistentlength
sklearnutils checkconsistentlength arrays
Check that all arrays have consistent first dimensions
Checks whether all objects in arrays have the same shape or length
Parameters
arrays list or tuple of input objects Objects that will be checked for consistent length
6399sklearnutils checkrandomstate
sklearnutils checkrandomstate seed
Turn seed into a nprandomRandomState instance
Parameters
seed None int instance of RandomState If seed is None return the RandomState singleton
used by nprandom If seed is an int return a new RandomState instance seeded with seed
If seed is already a RandomState instance return it Otherwise raise ValueError
Examples using sklearnutilscheckrandomstate
•Isotonic Regression
•Face completion with a multioutput estimators
•Empirical evaluation of the impact of kmeans initialization
•MNIST classfification using multinomial logistic L1
•Manifold Learning methods on a severed sphere
•Scaling the regularization parameter for SVCs

63910sklearnutilsclassweight computeclassweight
sklearnutilsclassweight computeclassweight classweight classes y
Estimate class weights for unbalanced datasets
Parameters
classweight dict ‘balanced’ or None If ‘balanced’ class weights will be given by
nsamples nclasses npbincounty If a dictionary is given keys
are classes and values are corresponding class weights If None is given the class weights
will be uniform
classes ndarray Array of the classes occurring in the data as given by npuniqueyorg
withyorg the original class labels
yarraylike shape nsamples Array of original class labels per sample
Returns
classweightvect ndarray shape nclasses Array with classweightvecti the weight for
ith class
References
The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data King Zen 2001
63911sklearnutilsclassweight computesampleweight
sklearnutilsclassweight computesampleweight classweight yindicesNone
Estimate sample weights by class for unbalanced datasets
Parameters
classweight dict list of dicts “balanced” or None optional Weights associated with classes
in the form classlabel weight If not given all classes are supposed to have
weight one For multioutput problems a list of dicts can be provided in the same order as
the columns of y
Note that for multioutput including multilabel weights should be defined for each class of
every column in its own dict For example for fourclass multilabel classification weights
should be 0 1 1 1 0 1 1 5 0 1 1 1 0 1 1 1 instead of 11 25
31 41
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data nsamples nclasses np
bincounty
For multioutput the weights of each column of y will be multiplied
yarraylike shape nsamples or nsamples noutputs Array of original class labels per
sample
indices arraylike shape nsubsample or None Array of indices to be used in a subsample
Can be of length less than nsamples in the case of a subsample or equal to nsamples in
the case of a bootstrap subsample with repeated indices If None the sample weight will
be calculated over the full sample Only “balanced” is supported for classweight if this is
provided
Returns

sampleweightvect ndarray shape nsamples Array with sample weights as applied to
the original y
63912sklearnutils deprecated
sklearnutils deprecated extra‘‘
Decorator to mark a function or class as deprecated
Issue a warning when the function is calledthe class is instantiated and adds a warning to the docstring
The optional extra argument will be appended to the deprecation message and the docstring Note to use this
with the default value for extra put in an empty of parentheses
```
 from sklearnutils import deprecated
deprecated
sklearnutilsdeprecationdeprecated object at
 deprecated
 def somefunction pass
```
Parameters
extra string to be added to the deprecation messages
63913sklearnutilsestimatorchecks checkestimator
sklearnutilsestimatorchecks checkestimator Estimator
Check if estimator adheres to scikitlearn conventions
This estimator will run an extensive testsuite for input validation shapes etc Additional tests for classifiers
regressors clustering or transformers will be run if the Estimator class inherits from the corresponding mixin
from sklearnbase
This test can be applied to classes or instances Classes currently have some additional tests that related to
construction while passing instances allows the testing of multiple options
Parameters
estimator estimator object or class Estimator to check Estimator is a class object or instance
63914sklearnutilsextmath safesparsedot
sklearnutilsextmath safesparsedot abdenseoutputFalse
Dot product that handle the sparse matrix case correctly
Uses BLAS GEMM as replacement for numpydot where possible to avoid unnecessary copies
Parameters
aarray or sparse matrix
barray or sparse matrix
denseoutput boolean default False When False either aorbbeing sparse will yield sparse
output When True output will always be an array
Returns

dotproduct array or sparse matrix sparse if aorbis sparse and denseoutputFalse
63915sklearnutilsextmath randomizedrangefinder
sklearnutilsextmath randomizedrangefinder A size niter
poweriterationnormalizer’auto’
randomstateNone
Computes an orthonormal matrix whose range approximates the range of A
Parameters
A2D array The input data matrix
size integer Size of the return array
niter integer Number of power iterations used to stabilize the result
poweriterationnormalizer ‘auto’ default ‘QR’ ‘LU’ ‘none’ Whether the power iter
ations are normalized with stepbystep QR factorization the slowest but most accurate
‘none’ the fastest but numerically unstable when niter is large eg typically 5 or
larger or ‘LU’ factorization numerically stable but can lose slightly in accuracy The
‘auto’ mode applies no normalization if niter 2 and switches to LU otherwise
New in version 018
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator to use when shuffling the data If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
Returns
Q2D array A size x size projection matrix the range of which approximates well the range
of the input matrix A
Notes
Follows Algorithm 43 of Finding structure with randomness Stochastic algorithms for constructing approxi
mate matrix decompositions Halko et al 2009 arXiv909 httpsarxivorgpdf09094061pdf
An implementation of a randomized algorithm for principal component analysis A Szlam et al 2014
63916sklearnutilsextmath randomizedsvd
sklearnutilsextmath randomizedsvd Mncomponents noversamples10 niter’auto’
poweriterationnormalizer’auto’ transpose’auto’
flipsignTrue randomstate0
Computes a truncated randomized SVD
Parameters
Mndarray or sparse matrix Matrix to decompose
ncomponents int Number of singular values and vectors to extract
noversamples int default is 10 Additional number of random vectors to sample the range
of M so as to ensure proper conditioning The total number of random vectors used to find

the range of M is ncomponents noversamples Smaller number can improve speed but
can negatively impact the quality of approximation of singular vectors and singular values
niter int or ‘auto’ default is ‘auto’ Number of power iterations It can be used to deal
with very noisy problems When ‘auto’ it is set to 4 unless ncomponents is small
1 minXshape niter in which case is set to 7 This improves precision with few
components
Changed in version 018
poweriterationnormalizer ‘auto’ default ‘QR’ ‘LU’ ‘none’ Whether the power iter
ations are normalized with stepbystep QR factorization the slowest but most accurate
‘none’ the fastest but numerically unstable when niter is large eg typically 5 or
larger or ‘LU’ factorization numerically stable but can lose slightly in accuracy The
‘auto’ mode applies no normalization if niter 2 and switches to LU otherwise
New in version 018
transpose True False or ‘auto’ default Whether the algorithm should be applied to MT
instead of M The result should approximately be the same The ‘auto’ mode will trigger
the transposition if Mshape1 Mshape0 since this implementation of randomized SVD
tend to be a little faster in that case
Changed in version 018
flipsign boolean True by default The output of a singular value decomposition is only
unique up to a permutation of the signs of the singular vectors If flipsign is set to
True the sign ambiguity is resolved by making the largest loadings for each component in
the left singular vectors positive
randomstate int RandomState instance or None optional defaultNone The seed of the
pseudo random number generator to use when shuffling the data If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom
Notes
This algorithm finds a usually very good approximate truncated singular value decomposition using random
ization to speed up the computations It is particularly fast on large matrices on which you wish to extract only
a small number of components In order to obtain further speed up niter can be set 2 at the cost of loss
of precision

63917sklearnutilsextmath fastlogdet
sklearnutilsextmath fastlogdet A
Compute logdetA for A symmetric
Equivalent to nplognldetA but more robust It returns Inf if detA is non positive or is not defined
Parameters
Aarraylike The matrix
63918sklearnutilsextmath density
sklearnutilsextmath densitywkwargs
Compute density of a sparse vector
Parameters
warraylike The sparse vector
Returns
float The density of w between 0 and 1
Examples using sklearnutilsextmathdensity
•Classification of text documents using sparse features
63919sklearnutilsextmath weightedmode
sklearnutilsextmath weightedmode awaxis0
Returns an array of the weighted modal most common value in a
If there is more than one such value only the first is returned The bincount for the modal bins is also returned
This is an extension of the algorithm in scipystatsmode
Parameters
aarraylike ndimensional array of which to find modes
warraylike ndimensional array of weights for each value
axis int optional Axis along which to operate Default is 0 ie the first axis
Returns
vals ndarray Array of modal values
score ndarray Array of weighted counts for each mode
See also
scipystatsmode
Examples

```
 from sklearnutilsextmath import weightedmode
x  4 1 4 2 4 2
weights  1 1 1 1 1 1
weightedmodex weights
array4 array3
```
The value 4 appears three times with uniform weights the result is simply the mode of the distribution
```
weights  1 3 05 15 1 2  deweight the 4s
weightedmodex weights
array2 array35
```
The value 2 has the highest score it appears twice with weights of 15 and 2 the sum of these is 35
63920sklearnutils genevenslices
sklearnutils genevenslices nnpacks nsamplesNone
Generator to create npacks slices going up to n
Parameters
nint
npacks int Number of slices to generate
nsamples int or None default None Number of samples Pass nsamples when the slices
are to be used for sparse matrix indexing slicing offtheend raises an exception while it
works for NumPy arrays
Yields
slice
Examples
```
 from sklearnutils import genevenslices
listgenevenslices10 1
slice0 10 None
listgenevenslices10 10
slice0 1 None slice1 2 None  slice9 10 None
listgenevenslices10 5
slice0 2 None slice2 4 None  slice8 10 None
listgenevenslices10 3
slice0 4 None slice4 7 None slice7 10 None
```
63921sklearnutilsgraph singlesourceshortestpathlength
sklearnutilsgraph singlesourceshortestpathlength graph source cut
offNone
Return the shortest path length from source to all reachable nodes
Returns a dictionary of shortest path lengths keyed by target
Parameters
graph sparse matrix or 2D array preferably LIL matrix Adjacency matrix of the graph

source integer Starting node for path
cutoff integer optional Depth to stop the search only paths of length cutoff are returned
Examples
 from sklearnutilsgraph import singlesourceshortestpathlength
 import numpy as np
graph nparray 0 1 0 0
  1 0 1 0
  0 1 0 1
  0 0 1 0
listsortedsinglesourceshortestpathlengthgraph 0items
0 0 1 1 2 2 3 3
graph nponesn 6 6
listsortedsinglesourceshortestpathlengthgraph 2items
0 1 1 1 2 0 3 1 4 1 5 1
63922sklearnutilsgraphshortestpath graphshortestpath
sklearnutilsgraphshortestpath graphshortestpath
Perform a shortestpath graph search on a positive directed or undirected graph
Parameters
distmatrix arraylike or sparse matrix shape NN Array of positive distances If vertex
i is connected to vertex j then distmatrixij gives the distance between the vertices If
vertex i is not connected to vertex j then distmatrixij 0
directed boolean if True then find the shortest path on a directed graph only progress from
a point to its neighbors not the other way around if False then find the shortest path on an
undirected graph the algorithm can progress from a point to its neighbors and vice versa
method string ‘auto’’FW’’D’ method to use Options are ‘auto’ attempt to choose the best
method for the current problem ‘FW’ FloydWarshall algorithm ON3 ‘D’ Dijkstra’s
algorithm with Fibonacci stacks OklogNN2
Returns
Gnpndarray float shape NN Gij gives the shortest distance from point i to point j
along the graph
Notes
As currently implemented Dijkstra’s algorithm does not work for graphs with directiondependent distances
when directed False ie if distmatrixij and distmatrixji are not equal and both are nonzero
method’D’ will not necessarily yield the correct result
Also these routines have not been tested for graphs with negative distances Negative distances can lead to
infinite cycles that must be handled by specialized algorithms
63923sklearnutils indexable
sklearnutils indexable iterables
Make arrays indexable for crossvalidation

Checks consistent length passes through None and ensures that everything can be indexed by converting sparse matrices to csr and converting noninterable objects to arrays
Parameters
iterables lists dataframes arrays sparse matrices List of objects to ensure sliceability
63924sklearnutilsmetaestimators ifdelegatehasmethod
sklearnutilsmetaestimators ifdelegatehasmethod delegate
Create a decorator for methods that are delegated to a subestimator
This enables ducktyping by hasattr returning True according to the subestimator
Parameters
delegate string list of strings or tuple of strings Name of the subestimator that can be accessed as an attribute of the base object If a list or a tuple of names are provided the first subestimator that is an attribute of the base object will be used
Examples using sklearnutilsmetaestimatorsifdelegatehasmethod
•Inductive Clustering
63925sklearnutilsmulticlass typeoftarget
sklearnutilsmulticlass typeoftarget y
Determine the type of data indicated by the target
Note that this type is the most specific type that can be inferred For example
•binary is more specific but compatible with multiclass
•multiclass of integers is more specific but compatible with continuous
•multilabelindicator is more specific but compatible with multiclassmultioutput
Parameters
yarraylike
Returns
targettype string One of
• ‘continuous’ yis an arraylike of floats that are not all integers and is 1d or a column vector
• ‘continuousmultioutput’ yis a 2d array of floats that are not all integers and both dimensions are of size 1
• ‘binary’ ycontains 2 discrete values and is 1d or a column vector
• ‘multiclass’ ycontains more than two discrete values is not a sequence of sequences and is 1d or a column vector
• ‘multiclassmultioutput’ yis a 2d array that contains more than two discrete values is not a sequence of sequences and both dimensions are of size 1
• ‘multilabelindicator’ yis a label indicator matrix an array of two dimensions with at least two columns and at most 2 unique values

• ‘unknown’ yis arraylike but none of the above such as a 3d array sequence of se
quences or an array of nonsequence objects
Examples
```
 import numpy as np
typeoftarget01 06
continuous
typeoftarget1 1 1 1
binary
typeoftargeta b a
binary
typeoftarget10 20
binary
typeoftarget1 0 2
multiclass
typeoftarget10 00 30
multiclass
typeoftargeta b c
multiclass
typeoftargetnparray1 2 3 1
multiclassmultioutput
typeoftarget1 2
multiclassmultioutput
typeoftargetnparray15 20 30 16
continuousmultioutput
typeoftargetnparray0 1 1 1
multilabelindicator
```
63926sklearnutilsmulticlass ismultilabel
sklearnutilsmulticlass ismultilabel y
Check ifyis in a multilabel format
Parameters
ynumpy array of shape nsamples Target values
Returns
out bool Return True ifyis in a multilabel format else False
Examples
```
 import numpy as np
 from sklearnutilsmulticlass import ismultilabel
ismultilabel0 1 0 1
False
ismultilabel1 0 2
False
ismultilabelnparray1 0 0 0
True
ismultilabelnparray1 0 0
False
```

ismultilabelnparray1 0 0
True
63927sklearnutilsmulticlass uniquelabels
sklearnutilsmulticlass uniquelabels ys
Extract an ordered array of unique labels
We don’t allow
• mix of multilabel and multiclass single label targets
• mix of label indicator matrix and anything else because there are no explicit labels
• mix of label indicator matrices of different sizes
• mix of string and integer labels
At the moment we also don’t allow “multiclassmultioutput” input type
Parameters
ys arraylikes
Returns
out numpy array of shape nuniquelabels An ordered array of unique labels
Examples
from sklearnutilsmulticlass import uniquelabels
uniquelabels3 5 5 5 7 7
array3 5 7
uniquelabels1 2 3 4 2 2 3 4
array1 2 3 4
uniquelabels1 2 10 5 11
array 1 2 5 10 11
Examples using sklearnutilsmulticlassuniquelabels
•Confusion matrix
63928sklearnutils murmurhash332
sklearnutils murmurhash332
Compute the 32bit murmurhash3 of key at seed
The underlying implementation is MurmurHash3x8632 generating low latency 32bits hash suitable for im
plementing lookup tables Bloom filters count min sketch or feature hashing
Parameters
key int32 bytes unicode or ndarray with dtype int32 the physical object to hash
seed int optional default is 0 integer seed for the hashing algorithm
positive boolean optional default is False

True the results is casted to an unsigned int from 0 to 2 32 1
False the results is casted to a signed int from 2 31 to 2 31 1
63929sklearnutils resample
sklearnutils resample arrays options
Resample arrays or sparse matrices in a consistent way
The default strategy implements one step of the bootstrapping procedure
Parameters
arrays sequence of indexable datastructures Indexable datastructures can be arrays lists dataframes or scipy sparse matrices with consistent first dimension
Returns
resampledarrays sequence of indexable datastructures Sequence of resampled copies of the collections The original arrays are not impacted
Other Parameters
replace boolean True by default Implements resampling with replacement If False this will implement sliced random permutations
nsamples int None by default Number of samples to generate If left to None this is automatically set to the first dimension of the arrays If replace is False it should not be larger than the length of arrays
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
stratify arraylike or None defaultNone If not None data is split in a stratified fashion using this as the class labels

resampley nsamples5 replace False stratifyy
 randomstate0
1 1 1 0 1
63930sklearnutils safeindexing
sklearnutils safeindexing Xindices
Return items or rows from X using indices
Allows simple indexing of lists or arrays
Parameters
Xarraylike sparsematrix list pandasDataFrame pandasSeries Data from which to sam
ple rows or items
indices arraylike of int Indices according to which X will be subsampled
Returns
subset Subset of X on first axis
Notes
CSR CSC and LIL sparse matrices are supported COO sparse matrices are not supported
63931sklearnutils safemask
sklearnutils safemask Xmask
Return a mask which is safe to use on X
Parameters
Xarraylike sparse matrix Data on which to apply mask
mask array Mask to be used on X
Returns

mask
63932sklearnutils safesqr
sklearnutils safesqr XcopyTrue
Element wise squaring of arraylikes and sparse matrices
Parameters
Xarray like matrix sparse matrix
copy boolean optional default True Whether to create a copy of X and operate on it or to perform inplace computation default behaviour
Returns
X 2 element wise square
63933sklearnutils shuffle
sklearnutils shufflearrays options
Shuffle arrays or sparse matrices in a consistent way
This is a convenience alias to resample arrays replaceFalse to do random permutations of the collections
Parameters
arrays sequence of indexable datastructures Indexable datastructures can be arrays lists dataframes or scipy sparse matrices with consistent first dimension
Returns
shuffledarrays sequence of indexable datastructures Sequence of shuffled copies of the col lections The original arrays are not impacted
Other Parameters
randomstate int RandomState instance or None optional defaultNone The seed of the pseudo random number generator to use when shuffling the data If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
nsamples int None by default Number of samples to generate If left to None this is auto matically set to the first dimension of the arrays

63934sklearnutilssparsefuncs incrmeanvarianceaxis

sklearnutilssparsefuncs incrmeanvarianceaxis Xaxislastmean lastvar lastn

Compute incremental mean and variance along an axix on a CSR or CSC matrix

lastmean lastvar are the statistics computed at the last step by this function Both must be initialized to 0 arrays of the proper size ie the number of features in X lastn is the number of samples encountered until now

Parameters

XCSR or CSC sparse matrix shape nsamples nfeatures Input data

axis int either 0 or 1 Axis along which the axis should be computed

lastmean float array with shape nfeatures Array of featurewise means to update with the new data X

lastvar float array with shape nfeatures Array of featurewise var to update with the new
data X
lastn int with shape nfeatures Number of samples seen so far excluded X
Returns
means float array with shape nfeatures Updated featurewise means
variances float array with shape nfeatures Updated featurewise variances
nint with shape nfeatures Updated number of seen samples
Notes
NaNs are ignored in the algorithm
63935sklearnutilssparsefuncs inplacecolumnscale
sklearnutilssparsefuncs inplacecolumnscale Xscale
Inplace column scaling of a CSCCSR matrix
Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a
nsamples nfeatures shape
Parameters
XCSC or CSR matrix with shape nsamples nfeatures Matrix to normalize using the vari
ance of the features
scale float array with shape nfeatures Array of precomputed featurewise values to use for
scaling
63936sklearnutilssparsefuncs inplacerowscale
sklearnutilssparsefuncs inplacerowscale Xscale
Inplace row scaling of a CSR or CSC matrix
Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a
nsamples nfeatures shape
Parameters
XCSR or CSC sparse matrix shape nsamples nfeatures Matrix to be scaled
scale float array with shape nfeatures Array of precomputed samplewise values to use for
scaling
63937sklearnutilssparsefuncs inplaceswaprow
sklearnutilssparsefuncs inplaceswaprow Xmn
Swaps two rows of a CSCCSR matrix inplace
Parameters
XCSR or CSC sparse matrix shapensamples nfeatures Matrix whose two rows are to
be swapped

mint Index of the row of X to be swapped
nint Index of the row of X to be swapped
63938sklearnutilssparsefuncs inplaceswapcolumn
sklearnutilssparsefuncs inplaceswapcolumn Xmn
Swaps two columns of a CSCCSR matrix inplace
Parameters
XCSR or CSC sparse matrix shapensamples nfeatures Matrix whose two columns are
to be swapped
mint Index of the column of X to be swapped
nint Index of the column of X to be swapped
63939sklearnutilssparsefuncs meanvarianceaxis
sklearnutilssparsefuncs meanvarianceaxis Xaxis
Compute mean and variance along an axix on a CSR or CSC matrix
Parameters
XCSR or CSC sparse matrix shape nsamples nfeatures Input data
axis int either 0 or 1 Axis along which the axis should be computed
Returns
means float array with shape nfeatures Featurewise means
variances float array with shape nfeatures Featurewise variances
63940sklearnutilssparsefuncs inplacecsrcolumnscale
sklearnutilssparsefuncs inplacecsrcolumnscale Xscale
Inplace column scaling of a CSR matrix
Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a
nsamples nfeatures shape
Parameters
XCSR matrix with shape nsamples nfeatures Matrix to normalize using the variance of
the features
scale float array with shape nfeatures Array of precomputed featurewise values to use for
scaling
63941sklearnutilssparsefuncsfast inplacecsrrownormalizel1
sklearnutilssparsefuncsfast inplacecsrrownormalizel1
Inplace row normalize using the l1 norm

63942sklearnutilssparsefuncsfast inplacecsrrownormalizel2
sklearnutilssparsefuncsfast inplacecsrrownormalizel2
Inplace row normalize using the l2 norm
63943sklearnutilsrandom samplewithoutreplacement
sklearnutilsrandom samplewithoutreplacement
Sample integers without replacement
Select nsamples integers from the set 0 npopulation without replacement
Parameters
npopulation int The size of the set to sample from
nsamples int The number of integer to sample
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
method “auto” “trackingselection” “reservoirsampling” or “pool” If method “auto”
the ratio of nsamples npopulation is used to determine which algorithm to use If ra
tio is between 0 and 001 tracking selection is used If ratio is between 001 and 099
numpyrandompermutation is used If ratio is greater than 099 reservoir sampling is used
The order of the selected integers is undefined If a random order is desired the selected
subset should be shuffled
If method ”trackingselection” a set based implementation is used which is suitable for
nsamples npopulation
If method “reservoirsampling” a reservoir sampling algorithm is used which is suitable
for high memory constraint or when O nsamples Onpopulation The order of the
selected integers is undefined If a random order is desired the selected subset should be
shuffled
If method “pool” a pool based algorithm is particularly fast even faster than the tracking
selection method Hovewer a vector containing the entire population has to be initialized
If nsamples npopulation the reservoir sampling method is faster
Returns
out array of size nsamples The sampled subsets of integer The subset of selected integer
might not be randomized see the method argument
63944sklearnutilsvalidation checkisfitted
sklearnutilsvalidation checkisfitted estimator attributes msgNone
alloranybuiltin function all
Perform isfitted validation for estimator
Checks if the estimator is fitted by verifying the presence of “allorany” of the passed attributes and raises a
NotFittedError with the given message
Parameters
estimator estimator instance estimator instance for which the check is performed

attributes attribute names given as string or a listtuple of strings
Egcoef estimator coef
msg string The default error message is “This names instance is not fitted yet Call ‘fit’
with appropriate arguments before using this method”
For custom messages if “names” is present in the message string it is substituted for the
estimator name
Eg “Estimator names must be fitted before sparsifying”
allorany callable all any default all Specify whether all or any of the given attributes
must exist
Returns
None
Raises
NotFittedError If the attributes are not found
63945sklearnutilsvalidation checkmemory
sklearnutilsvalidation checkmemory memory
Check that memory is joblibMemorylike
joblibMemorylike means that memory can be converted into a joblibMemory instance typically a str denoting
thelocation or has the same interface has a cache method
Parameters
memory None str or object with the joblibMemory interface
Returns
memory object with the joblibMemory interface
Raises
ValueError Ifmemory is not joblibMemorylike
63946sklearnutilsvalidation checksymmetric
sklearnutilsvalidation checksymmetric array tol1e10 raisewarningTrue
raiseexceptionFalse
Make sure that array is 2D square and symmetric
If the array is not symmetric then a symmetrized version is returned Optionally a warning or exception is
raised if the matrix is not symmetric
Parameters
array ndarray or sparse matrix Input object to check convert Must be twodimensional and
square otherwise a ValueError will be raised
tolfloat Absolute tolerance for equivalence of arrays Default 1E10
raisewarning boolean defaultTrue If True then raise a warning if conversion is required
raiseexception boolean defaultFalse If True then raise an exception if array is not sym
metric

Returns
arraysym ndarray or sparse matrix Symmetrized version of the input array ie the average
of array and arraytranspose If sparse then duplicate entries are first summed and zeros
are eliminated
63947sklearnutilsvalidation columnor1d
sklearnutilsvalidation columnor1d ywarnFalse
Ravel column or 1d numpy array else raises an error
Parameters
yarraylike
warn boolean default False To control display of warnings
Returns
yarray
63948sklearnutilsvalidation hasfitparameter
sklearnutilsvalidation hasfitparameter estimator parameter
Checks whether the estimator’s fit method supports the given parameter
Parameters
estimator object An estimator to inspect
parameter str The searched parameter
Returns
isparameter bool Whether the parameter was found to be a named parameter of the estima
tor’s fit method
Examples
 from sklearnsvm import SVC
hasfitparameterSVC sampleweight
True
63949sklearnutilstesting assertin
sklearnutilstesting assertin member container msgNone
Just like selfassertTruea in b but with a nicer default message
63950sklearnutilstesting assertnotin
sklearnutilstesting assertnotin member container msgNone
Just like selfassertTruea not in b but with a nicer default message

63951sklearnutilstesting assertraisemessage
sklearnutilstesting assertraisemessage exceptions message function args
kwargs
Helper function to test the message raised in an exception
Given an exception a callable to raise the exception and a message string tests that the correct exception is raised and that the message is a substring of the error thrown Used to test that the specific message thrown during an exception is correct
Parameters
exceptions exception or tuple of exception An Exception object
message str The error message or a substring of the error message
function callable Callable object to raise error
args the positional arguments to function
kwargs the keyword arguments to function
63952sklearnutilstesting allestimators
sklearnutilstesting allestimators includemetaestimatorsNone includeotherNone
typefilterNone includedonttestNone
Get a list of all estimators from sklearn
This function crawls the module and gets all classes that inherit from BaseEstimator Classes that are defined in testmodules are not included By default metaestimators such as GridSearchCV are also not included
Parameters
includemetaestimators boolean defaultFalse Deprecated ignored deprecated 021
includemetaestimators has been deprecated and has no effect in 021 and
will be removed in 023
includeother boolean defaultFalse Deprecated ignored deprecated 021
includeother has been deprecated and has not effect in 021 and will be removed
in 023
typefilter string list of string or None defaultNone Which kind of estimators should be returned If None no filter is applied and all estimators are returned Possible values are ‘classifier’ ‘regressor’ ‘cluster’ and ‘transformer’ to get estimators only of these specific types or a list of these to get the estimators that fit at least one of the types
includedonttest boolean defaultFalse Deprecated ignored deprecated 021
includedonttest has been deprecated and has no effect in 021 and will be
removed in 023
Returns
estimators list of tuples List of name class where name is the class name as string and class is the actuall type of the class
Utilities from joblib

utilsparallelbackend backend njobs Change the default backend used by Parallel inside a with
block
utilsregisterparallelbackend name fac
toryRegister a new Parallel backend factory
63953sklearnutils parallelbackend
sklearnutils parallelbackend backend njobs1 backendparams
Change the default backend used by Parallel inside a with block
Ifbackend is a string it must match a previously registered implementation using the
registerparallelbackend function
By default the following backends are available
• ‘loky’ singlehost processbased parallelism used by default
• ‘threading’ singlehost threadbased parallelism
• ‘multiprocessing’ legacy singlehost processbased parallelism
‘loky’ is recommended to run functions that manipulate Python objects ‘threading’ is a lowoverhead alternative
that is most efficient for functions that release the Global Interpreter Lock eg IObound code or CPUbound
code in a few calls to native code that explicitly releases the GIL
In addition if the dask anddistributed Python packages are installed it is possible to use the ‘dask’
backend for better scheduling of nested parallel calls without oversubscription and potentially distribute parallel
calls over a networked cluster of several hosts
Alternatively the backend can be passed directly as an instance
By default all available workers will be used njobs1 unless the caller passes an explicit value for the
njobs parameter
This is an alternative to passing a backendbackendname argument to the Parallel class construc
tor It is particularly useful when calling into library code that uses joblib internally but does not expose the
backend argument in its own API
 from operator import neg
 with parallelbackendthreading
 printParalleldelayednegi 1 foriinrange5

1 2 3 4 5
Warning this function is experimental and subject to change in a future version of joblib
New in version 010
63954sklearnutils registerparallelbackend
sklearnutils registerparallelbackend name factory makedefaultFalse
Register a new Parallel backend factory
The new backend can then be selected by passing its name as the backend argument to the Parallel class
Moreover the default backend can be overwritten globally by setting makedefaultTrue
The factory can be any callable that takes no argument and return an instance of ParallelBackendBase
Warning this function is experimental and subject to change in a future version of joblib

scikitlearn user guide Release 0213
New in version 010
640 Recently deprecated
6401 To be removed in 023

sklearnutils Memory
Warning DEPRECATED
classsklearnutils Memoryargs kwargs
Attributes
cachedir
Methods
cache self func ignore verbose mmapmode Decorates the given function func to only compute its
return value for input arguments not cached on disk
clear self warn Erase the complete cache directory
eval self func args kwargs Eval function func with arguments args and
kwargs in the context of the memory
format self obj indent Return the formatted representation of the object
reducesize self Remove cache elements to make cache size fit in
byteslimit
debug
warn
init args kwargs
DEPRECATED deprecated in version 0201 to be removed in version 023 Please import this function
ality directly from joblib which can be installed with pip install joblib
cacheselffuncNone ignoreNone verboseNone mmapmodeFalse
Decorates the given function func to only compute its return value for input arguments not cached on disk
Parameters

func callable optional The function to be decorated
ignore list of strings A list of arguments name to ignore in the hashing
verbose integer optional The verbosity mode of the function By default that of the mem
ory object is used
mmapmode None ‘r’ ‘r’ ‘w’ ‘c’ optional The memmapping mode used when
loading from cache numpy arrays See numpyload for the meaning of the arguments
By default that of the memory object is used
Returns
decoratedfunc MemorizedFunc object The returned object is a MemorizedFunc object
that is callable behaves like a function but offers extra methods for cache lookup and
management See the documentation for joblibmemoryMemorizedFunc
clearselfwarnTrue
Erase the complete cache directory
evalselffuncargs kwargs
Eval function func with arguments args andkwargs in the context of the memory
This method works similarly to the builtin apply except that the function is called only if the cache is
not up to date
formatselfobjindent0
Return the formatted representation of the object
reducesize self
Remove cache elements to make cache size fit in byteslimit
sklearnutils Parallel
Warning DEPRECATED
classsklearnutils Parallel args kwargs
Methods
call self iterable
dispatchnext self Dispatch more data for parallel processing
dispatchonebatch self iterator Prefetch the tasks for the next batch and dispatch them
format self obj indent Return the formatted representation of the object
printprogress self Display the process of the parallel execution only a frac
tion of time controlled by selfverbose
debug
retrieve
warn
init args kwargs
DEPRECATED deprecated in version 0201 to be removed in version 023 Please import this function
640 Recently deprecated 2387

ality directly from joblib which can be installed with pip install joblib
dispatchnext self
Dispatch more data for parallel processing
This method is meant to be called concurrently by the multiprocessing callback We rely on the thread safety of dispatchonebatch to protect against concurrent consumption of the unprotected iterator
dispatchonebatch selfiterator
Prefetch the tasks for the next batch and dispatch them
The effective size of the batch is computed here If there are no more jobs to dispatch return False else return True
The iterator consumption and dispatching is protected by the same lock so calling this function should be thread safe
formatselfobjindent0
Return the formatted representation of the object
printprogress self
Display the process of the parallel execution only a fraction of time controlled by selfverbose

scikitlearn user guide Release 0213
Decorator used to capture the arguments of a function
sklearnmetrics calinskiharabazscore
Warning DEPRECATED
sklearnmetrics calinskiharabazscore Xlabels
DEPRECATED Function ‘calinskiharabazscore’ has been renamed to ‘calinskiharabaszscore’ and will be removed in version 023
sklearnmetrics jaccardsimilarityscore
Warning DEPRECATED
sklearnmetrics jaccardsimilarityscore ytrue ypred normalizeTrue sam pleweightNone
Jaccard similarity coefficient score
Deprecated since version 021 This is deprecated to be removed in 023 since its handling of binary and multiclass inputs was broken jaccardscore has an API that is consistent with precisionscore fscore etc
Read more in the User Guide
Parameters
ytrue 1d arraylike or label indicator array sparse matrix Ground truth correct labels
ypred 1d arraylike or label indicator array sparse matrix Predicted labels as returned by a classifier
normalize bool optional defaultTrue If False return the sum of the Jaccard similarity coefficient over the sample set Otherwise return the average of Jaccard similarity coeffi cient
sampleweight arraylike of shape nsamples optional Sample weights
Returns
score float Ifnormalize True return the average Jaccard similarity coefficient else it returns the sum of the Jaccard similarity coefficient over the sample set
The best performance is 1 with normalize True and the number of samples with normalize False
See also
accuracyscore hammingloss zerooneloss
Notes
In binary and multiclass classification this function is equivalent to the accuracyscore It differs in the multilabel classification problem
640 Recently deprecated 2389

DEPRECATED logisticregressionpath was deprecated in version 021 and will be removed in version 0230
Compute a Logistic Regression model for a list of regularization parameters
This is an implementation that uses the result of the previous model to speed up computations along the
set of solutions making it faster than sequentially calling LogisticRegression for the different parameters
Note that there will be no speedup with liblinear solver since it does not handle warmstarting
Deprecated since version 021 logisticregressionpath was deprecated in version 021 and
will be removed in 023
Read more in the User Guide
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures
Input data
yarraylike shape nsamples or nsamples ntargets Input data target values
posclass int None The class with respect to which we perform a onevsall fit If None
then it is assumed that the given problem is binary
Csint arraylike shape ncs List of values for the regularization parameter or integer
specifying the number of regularization parameters that should be used In this case the
parameters will be chosen in a logarithmic scale between 1e4 and 1e4
fitintercept bool Whether to fit an intercept for the model In this case the shape of the
returned array is ncs nfeatures 1
maxiter int Maximum number of iterations for the solver
tolfloat Stopping criterion For the newtoncg and lbfgs solvers the iteration will stop
whenmaxgi i 1 n tol wheregi is the ith component
of the gradient
verbose int For the liblinear and lbfgs solvers set verbose to any positive number for
verbosity
solver 'lbfgs' 'newtoncg' 'liblinear' 'sag' 'saga' Numerical solver to use

coef arraylike shape nfeatures default None Initialization value for coefficients of
logistic regression Useless for liblinear solver
classweight dict or ‘balanced’ optional Weights associated with classes in the form
classlabel weight If not given all classes are supposed to have weight
one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses
npbincounty
Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified
dual bool Dual or primal formulation Dual formulation is only implemented for l2
penalty with liblinear solver Prefer dualFalse when nsamples nfeatures
penalty str ‘l1’ ‘l2’ or ‘elasticnet’ Used to specify the norm used in the penalization
The ‘newtoncg’ ‘sag’ and ‘lbfgs’ solvers support only l2 penalties ‘elasticnet’ is only
supported by the ‘saga’ solver
interceptscaling float default 1 Useful only when the solver ‘liblinear’ is used and
selffitintercept is set to True In this case x becomes x selfinterceptscaling
ie a “synthetic” feature with constant value equal to interceptscaling is ap
pended to the instance vector The intercept becomes interceptscaling
syntheticfeatureweight
Note the synthetic feature weight is subject to l1l2 regularization as all other features
To lessen the effect of regularization on synthetic feature weight and therefore on the
intercept interceptscaling has to be increased
multiclass str ‘ovr’ ‘multinomial’ ‘auto’ default ‘ovr’ If the option chosen is ‘ovr’
then a binary problem is fit for each label For ‘multinomial’ the loss minimised is the
multinomial loss fit across the entire probability distribution even when the data is binary
‘multinomial’ is unavailable when solver’liblinear’ ‘auto’ selects ‘ovr’ if the data is
binary or if solver’liblinear’ and otherwise selects ‘multinomial’
New in version 018 Stochastic Average Gradient descent solver for ‘multinomial’ case
Changed in version 020 Default will change from ‘ovr’ to ‘auto’ in 022
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator to use when shuffling the data If int randomstate is
the seed used by the random number generator If RandomState instance randomstate is
the random number generator If None the random number generator is the RandomState
instance used by nprandom Used when solver ‘sag’ or ‘liblinear’
checkinput bool default True If False the input arrays X and y will not be checked
maxsquaredsum float default None Maximum squared sum of X over samples Used
only in SAG solver If None it will be computed going through all the samples The
value should be precomputed to speed up cross validation
sampleweight arraylike shapensamples optional Array of weights that are assigned
to individual samples If not provided then each sample is given unit weight
l1ratio float or None optional defaultNone The ElasticNet mixing parameter
with0 l1ratio 1 Only used if penaltyelasticnet Setting
l1ratio0 is equivalent to using penaltyl2 while setting l1ratio1 is
equivalent to using penaltyl1 For0 l1ratio 1 the penalty is a com
bination of L1 and L2
640 Recently deprecated 2391

Returns
coefs ndarray shape ncs nfeatures or ncs nfeatures 1
List of coefficients for the Logistic Regression model If fitintercept is set to True
then the second dimension will be nfeatures 1 where the last item represents
the intercept For multiclassmultinomial the shape is nclasses ncs
nfeatures or nclasses ncs nfeatures 1
Csndarray Grid of Cs used for crossvalidation
niter array shape ncs Actual number of iteration for each Cs
Notes
You might get slightly different results with the solver liblinear than with the others since this uses LIBLINEAR
which penalizes the intercept
Changed in version 019 The “copy” parameter was removed
ensemblepartialdependence
partialdependence DEPRECATED The function ensem
blepartialdependence has been deprecated in favour
of inspectionpartialdependence in 021 and will be
removed in 023
ensemblepartialdependence

021 and will be removed in 023
sklearnensemblepartialdependence partialdependence
sklearnensemblepartialdependence partialdependence gbrt targetvariables
gridNone XNone
percentiles005 095
gridresolution100
DEPRECATED The function ensemblepartialdependence has been deprecated in favour of inspec
tionpartialdependence in 021 and will be removed in 023
Partial dependence of targetvariables
Partial dependence plots show the dependence between the joint values of the
targetvariables and the function represented by the gbrt
Read more in the User Guide
Deprecated since version 021 This function was deprecated in version 021 in favor of sklearn
inspectionpartialdependence and will be removed in 023
Parameters
gbrt BaseGradientBoosting
A fitted gradient boosting model
targetvariables arraylike dtypeint The target features for which the partial depen
dency should be computed size should be smaller than 3 for visual renderings

scikitlearn user guide Release 0213
grid arraylike shapenpoints lentargetvariables The grid of
targetvariables values for which the partial dependency should be evalu
ated either grid orXmust be specified
Xarraylike shapensamples nfeatures The data on which gbrt was trained It
is used to generate a grid for thetargetvariables Thegrid comprises
gridresolution equally spaced points between the two percentiles
percentiles low high default005 095 The lower and upper percentile used create
the extreme values for the grid Only ifXis not None
gridresolution int default100 The number of equally spaced points on the grid
Returns
pdp array shapenclasses npoints
The partial dependence function evaluated on the grid For regression and binary
classification nclasses1
axes seq of ndarray or None The axes with which the grid has been created or None if the
grid has been given
Examples
samples 0 0 2 1 0 0

Partial dependence plots for features
Thelenfeatures plots are arranged in a grid with ncols columns Twoway partial depen
dence plots are plotted as contour plots
Read more in the User Guide
640 Recently deprecated 2393

Deprecated since version 021 This function was deprecated in version 021 in favor of sklearn
inspectionplotpartialdependence and will be removed in 023
Parameters
gbrt BaseGradientBoosting
A fitted gradient boosting model
Xarraylike shapensamples nfeatures The data on which gbrt was trained
features seq of ints strings or tuples of ints or strings If seqi is an int or a tuple
with one int value a oneway PDP is created if seqi is a tuple of two ints a two
way PDP is created If featurenames is specified and seqi is an int seqi must be
lenfeaturenames If seqi is a string featurenames must be specified and seqi must
be in featurenames
featurenames seq of str Name of each feature featurenamesi holds the name of the
feature with index i
label object The class label for which the PDPs should be computed Only if gbrt is a
multiclass model Must be in gbrtclasses
ncols int The number of columns in the grid plot default 3
gridresolution int default100 The number of equally spaced points on the axes
percentiles low high default005 095 The lower and upper percentile used to create
the extreme values for the PDP axes
njobs int or None optional defaultNone None means 1 unless in a joblib
parallelbackend context1means using all processors See Glossary for more
details
verbose int Verbose output during PD computations Defaults to 0
axMatplotlib axis object default None An axis object onto which the plots will be drawn
linekw dict Dict with keywords passed to the matplotlibpyplotplot call For
oneway partial dependence plots
contourkw dict Dict with keywords passed to the matplotlibpyplotplot call
For twoway partial dependence plots
figkw dict Dict with keywords passed to the figure call Note that all keywords not
recognized above will be automatically included here
Returns
figfigure
The Matplotlib Figure object
axs seq of Axis objects A seq of Axis objects one for each subplot
Examples
```
 from sklearndatasets import makefriedman1
 from sklearnensemble import GradientBoostingRegressor
X y  makefriedman1
clf  GradientBoostingRegressornestimators10fitX y

sklearncovariance GraphLasso
Warning DEPRECATED
classsklearncovariance GraphLasso args kwargs
Sparse inverse covariance estimation with an l1penalized estimator
This class implements the Graphical Lasso algorithm
Read more in the User Guide
Parameters
alpha positive float default 001 The regularization parameter the higher alpha the more regularization the sparser the inverse covariance
mode ‘cd’ ‘lars’ default ‘cd’ The Lasso solver to use coordinate descent or LARS Use LARS for very sparse underlying graphs where p n Elsewhere prefer cd which is more numerically stable
tolpositive float default 1e4 The tolerance to declare convergence if the dual gap goes below this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate the descent direction This parameter controls the accuracy of the search direction for a given column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer default 100 The maximum number of iterations
verbose boolean default False If verbose is True the objective function and dual gap are plotted at each iteration
assumecentered boolean default False If True data are not centered before computation Useful when working with data whose mean is almost but not exactly zero If False data are centered before computation
Attributes
covariance arraylike shape nfeatures nfeatures Estimated covariance matrix
precision arraylike shape nfeatures nfeatures Estimated pseudo inverse matrix
niter int Number of iterations run
640 Recently deprecated 2395

DEPRECATED The ‘GraphLasso’ was renamed to ‘GraphicalLasso’ in version 020 and will be removed
in 022
errornorm selfcompcov norm’frobenius’ scalingTrue squaredTrue
Computes the Mean Squared Error between two covariance estimators In the sense of the Frobenius
norm
Parameters
compcov arraylike shape nfeatures nfeatures The covariance to compare with
norm str The type of norm used to compute the error Available error types ‘frobenius’
default sqrttrAtA ‘spectral’ sqrtmaxeigenvaluesAtA where A is the error
compcov selfcovariance
scaling bool If True default the squared error norm is divided by nfeatures If False
the squared error norm is not rescaled
squared bool Whether to compute the squared error norm or the error norm If True
default the squared error norm is returned If False the error norm is returned
Returns
The Mean Squared Error in the sense of the Frobenius norm between
self andcompcov covariance estimators
fitselfXyNone
Fits the GraphicalLasso model to X
Parameters
Xndarray shape nsamples nfeatures Data from which to compute the covariance es
timate
yignored
getparams selfdeepTrue
Get parameters for this estimator

Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Getter for the precision matrix
Returns
precision arraylike The precision matrix associated to the current covariance object
mahalanobis selfX
Computes the squared Mahalanobis distances of given observations
Parameters
Xarraylike shape nsamples nfeatures The observations the Mahalanobis distances
of the which we compute Observations are assumed to be drawn from the same distribu
tion than the data used in fit
Returns
dist array shape nsamples Squared Mahalanobis distances of the observations
scoreselfXtest yNone
Computes the loglikelihood of a Gaussian data set with selfcovariance as an estimator of its
covariance matrix
Parameters
Xtest arraylike shape nsamples nfeatures Test data of which we compute the
likelihood where nsamples is the number of samples and nfeatures is the number of
features Xtest is assumed to be drawn from the same distribution than the data used in
fit including centering
ynot used present for API consistence purpose
Returns
resfloat The likelihood of the data set with selfcovariance as an estimator of its
covariance matrix
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sklearncovariance GraphLassoCV
Warning DEPRECATED
640 Recently deprecated 2397

classsklearncovariance GraphLassoCV args kwargs
Sparse inverse covariance w crossvalidated choice of the l1 penalty
See glossary entry for crossvalidation estimator
This class implements the Graphical Lasso algorithm
Read more in the User Guide
Parameters
alphas integer or list positive float optional If an integer is given it fixes the number of points on the grids of alpha to be used If a list is given it gives the grid to be used See the notes in the class docstring for more details
nrefinements strictly positive integer The number of times the grid is refined Not used if explicit values of alphas are passed
cvint crossvalidation generator or an iterable optional Determines the crossvalidation splitting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
tolpositive float optional The tolerance to declare convergence if the dual gap goes below this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate the descent direction This parameter controls the accuracy of the search direction for a given column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer optional Maximum number of iterations
mode ‘cd’ ‘lars’ The Lasso solver to use coordinate descent or LARS Use LARS for very sparse underlying graphs where number of features is greater than number of samples Elsewhere prefer cd which is more numerically stable
njobs int or None optional defaultNone number of jobs to run in parallel None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
verbose boolean optional If verbose is True the objective function and duality gap are printed at each iteration
assumecentered Boolean If True data are not centered before computation Useful when working with data whose mean is almost but not exactly zero If False data are centered before computation
Attributes
covariance numpyndarray shape nfeatures nfeatures Estimated covariance matrix
precision numpyndarray shape nfeatures nfeatures Estimated precision matrix inverse covariance

alpha float Penalization parameter selected
cvalphas list of float All penalization parameters explored
gridscores 2D numpyndarray nalphas nfolds Loglikelihood score on leftout data
across folds
niter int Number of iterations run for the optimal alpha
See also
graphlasso GraphLasso
Notes
The search for the optimal penalization parameter alpha is done on an iteratively refined grid first the cross
validated scores on a grid are computed then a new refined grid is centered around the maximum and so on
One of the challenges which is faced here is that the solvers can fail to converge to a wellconditioned estimate
The corresponding values of alpha then come out as missing values but the optimum may be close to these
missing values
Methods
errornorm self compcov norm scaling Computes the Mean Squared Error between two covari
ance estimators
fitself X y Fits the GraphicalLasso covariance model to X
getparams self deep Get parameters for this estimator

mahalanobis self X Computes the squared Mahalanobis distances of given
observations
score self Xtest y Computes the loglikelihood of a Gaussian data set with
selfcovariance as an estimator of its covari
ance matrix
setparams self params Set the parameters of this estimator
init args kwargs
DEPRECATED The ‘GraphLassoCV‘ was renamed to ‘GraphicalLassoCV‘ in version 020 and will be
removed in 022
errornorm selfcompcov norm’frobenius’ scalingTrue squaredTrue
Computes the Mean Squared Error between two covariance estimators In the sense of the Frobenius
norm
Parameters
compcov arraylike shape nfeatures nfeatures The covariance to compare with
norm str The type of norm used to compute the error Available error types ‘frobenius’
default sqrttrAtA ‘spectral’ sqrtmaxeigenvaluesAtA where A is the error
compcov selfcovariance
scaling bool If True default the squared error norm is divided by nfeatures If False
the squared error norm is not rescaled
squared bool Whether to compute the squared error norm or the error norm If True

default the squared error norm is returned If False the error norm is returned
Returns
The Mean Squared Error in the sense of the Frobenius norm between
self andcompcov covariance estimators
fitselfXyNone
Fits the GraphicalLasso covariance model to X
Parameters
Xndarray shape nsamples nfeatures Data from which to compute the covariance es
timate
yignored
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
getprecision self
Getter for the precision matrix
Returns
precision arraylike The precision matrix associated to the current covariance object
mahalanobis selfX
Computes the squared Mahalanobis distances of given observations
Parameters
Xarraylike shape nsamples nfeatures The observations the Mahalanobis distances
of the which we compute Observations are assumed to be drawn from the same distribu
tion than the data used in fit
Returns
dist array shape nsamples Squared Mahalanobis distances of the observations
scoreselfXtest yNone
Computes the loglikelihood of a Gaussian data set with selfcovariance as an estimator of its
covariance matrix
Parameters
Xtest arraylike shape nsamples nfeatures Test data of which we compute the
likelihood where nsamples is the number of samples and nfeatures is the number of
features Xtest is assumed to be drawn from the same distribution than the data used in
fit including centering
ynot used present for API consistence purpose
Returns
resfloat The likelihood of the data set with selfcovariance as an estimator of its
covariance matrix

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sklearnpreprocessing Imputer
Warning DEPRECATED
classsklearnpreprocessing Imputerargs kwargs
Imputation transformer for completing missing values
Read more in the User Guide
Parameters
missingvalues integer or “NaN” optional default”NaN” The placeholder for the miss
ing values All occurrences of missingvalues will be imputed For missing values
encoded as npnan use the string value “NaN”
strategy string optional default”mean” The imputation strategy
• If “mean” then replace missing values using the mean along the axis
• If “median” then replace missing values using the median along the axis
• If “mostfrequent” then replace missing using the most frequent value along the axis
axis integer optional default0 The axis along which to impute
• Ifaxis0 then impute along columns
• Ifaxis1 then impute along rows
verbose integer optional default0 Controls the verbosity of the imputer
copy boolean optional defaultTrue If True a copy of X will be created If False imputation
will be done inplace whenever possible Note that in the following cases a new copy will
always be made even if copyFalse
• If X is not an array of floating values
• If X is sparse and missingvalues0
• Ifaxis0 and X is encoded as a CSR matrix
• Ifaxis1 and X is encoded as a CSC matrix
Attributes
statistics array of shape nfeatures The imputation fill value for each feature if axis 0

Notes
• Whenaxis0 columns which only contained missing values at fit are discarded upon transform
• Whenaxis1 an exception is raised if there are rows for which it is not possible to fill in the missing values eg because they only contain missing values
Methods
fitself X y Fit the imputer on X
fittransform self X y Fit to data then transform it
getparams self deep Get parameters for this estimator
setparams self params Set the parameters of this estimator
transform self X Impute all missing values in X
init args kwargs
DEPRECATED Imputer was deprecated in version 020 and will be removed in 022 Import im puteSimpleImputer from sklearn instead
fitselfXyNone
Fit the imputer on X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Input data where nsamples is the number of samples and nfeatures is the number of features
Returns
self Imputer
fittransform selfXyNone fitparams
Fit to data then transform it
Fits transformer to X and y with optional parameters fitparams and returns a transformed version of X
Parameters
Xnumpy array of shape nsamples nfeatures Training set
ynumpy array of shape nsamples Target values
Returns
Xnew numpy array of shape nsamples nfeaturesnew Transformed array
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
setparams selfparams
Set the parameters of this estimator

The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
transform selfX
Impute all missing values in X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input data to complete
sklearnutilstesting mockmldataurlopen
Warning DEPRECATED
classsklearnutilstesting mockmldataurlopen args kwargs
Object that mocks the urlopen function to fake requests to mldata
When requesting a dataset with a name that is in mockdatasets this object creates a fake dataset in a StringIO
object and returns it Otherwise it raises an HTTPError
Deprecated since version 020 Will be removed in version 022
Parameters
mockdatasets dict A dictionary of datasetname datadict or datasetname datadict
ordering datadict itself is a dictionary of columnname dataarray and
ordering is a list of columnnames to determine the ordering in the data set see
fakemldata for details
Methods
call self urlname
Parameters

sklearncovariance graphlasso empcov alpha covinitNone mode’cd’ tol00001
enettol00001 maxiter100 verboseFalse re
turncostsFalse eps2220446049250313e16 re
turnniterFalse
DEPRECATED The ‘graphlasso’ was renamed to ‘graphicallasso’ in version 020 and will be removed in
022
l1penalized covariance estimator
Read more in the User Guide
Parameters
empcov 2D ndarray shape nfeatures nfeatures
Empirical covariance from which to compute the covariance estimate
alpha positive float The regularization parameter the higher alpha the more regulariza
tion the sparser the inverse covariance
covinit 2D array nfeatures nfeatures optional The initial guess for the covariance
mode ‘cd’ ‘lars’ The Lasso solver to use coordinate descent or LARS Use LARS
for very sparse underlying graphs where p n Elsewhere prefer cd which is more
numerically stable
tolpositive float optional The tolerance to declare convergence if the dual gap goes
below this value iterations are stopped
enettol positive float optional The tolerance for the elastic net solver used to calculate
the descent direction This parameter controls the accuracy of the search direction for a
given column update not of the overall parameter estimate Only used for mode’cd’
maxiter integer optional The maximum number of iterations
verbose boolean optional If verbose is True the objective function and dual gap are
printed at each iteration
returncosts boolean optional If returncosts is True the objective function and dual
gap at each iteration are returned
eps float optional The machineprecision regularization in the computation of the
Cholesky diagonal factors Increase this for very illconditioned systems
returnniter bool optional Whether or not to return the number of iterations
Returns
covariance 2D ndarray shape nfeatures nfeatures
The estimated covariance matrix
precision 2D ndarray shape nfeatures nfeatures The estimated sparse precision
matrix

costs list of objective dualgap pairs The list of values of the objective function and the
dual gap at each iteration Returned only if returncosts is True
niter int Number of iterations Returned only if returnniter is set to True
Notes
The algorithm employed to solve this problem is the GLasso algorithm from the Friedman 2008 Biostatistics
paper It is the same algorithm as in the R glasso package
One possible difference with the glasso R package is that the diagonal coefficients are not penalized
sklearndatasets fetchmldata
Warning DEPRECATED
sklearndatasets fetchmldata dataname targetname’label’ dataname’data’ trans
posedataTrue datahomeNone
DEPRECATED fetchmldata was deprecated in version 020 and will be removed in version 022 Please use
fetchopenml
Fetch an mldataorg data set
mldataorg is no longer operational
If the file does not exist yet it is downloaded from mldataorg
mldataorg does not have an enforced convention for storing data or naming the columns in a data
set The default behavior of this function works well with the most common cases
1 data values are stored in the column ‘data’ and target values in the column ‘label’
2 alternatively the first column stores target values and the second data values
3 the data array is stored as nfeatures x nsamples and thus needs to be transposed to
match thesklearn standard
Keyword arguments allow to adapt these defaults to specific data sets see parameters
targetname dataname transposedata and the examples below
mldataorg data sets may have multiple columns which are stored in the Bunch object with their
original name
Deprecated since version 020 Will be removed in version 022
Parameters
dataname str
Name of the data set on mldataorg eg “leukemia” “Whistler Daily Snowfall” etc
The raw name is automatically converted to a mldataorg URL
targetname optional default ‘label’ Name or index of the column containing the target
values
dataname optional default ‘data’ Name or index of the column containing the data
transposedata optional default True If True transpose the downloaded data array

datahome optional default None Specify another download and cache folder for the
data sets By default all scikitlearn data is stored in ‘scikitlearndata’ subfolders
Returns
data Bunch Dictionarylike object the interesting attributes are ‘data’ the data to learn
‘target’ the classification labels ‘DESCR’ the full description of the dataset and
‘COLNAMES’ the original names of the dataset columns
sklearndatasets mldatafilename
Warning DEPRECATED
sklearndatasets mldatafilename dataname
DEPRECATED mldatafilename was deprecated in version 020 and will be removed in version 022 Please
use fetchopenml
Convert a raw name for a data set in a mldataorg filename
Deprecated since version 020 Will be removed in version 022
Parameters
dataname str Name of dataset
Returns
fname str The converted dataname

CHAPTER
SEVEN
DEVELOPER'S GUIDE
71 Contributing
This project is a community effort and everyone is welcome to contribute
The project is hosted on httpsgithubcomscikitlearnscikitlearn
The decision making process and governance structure of scikitlearn is laid out in the governance document Scikit learn governance and decisionmaking
Scikitlearn is somewhat selective when it comes to adding new algorithms and the best way to contribute and to help the project is to start working on known issues See Issues for New Contributors to get started
Our community our values
We are a community based on openness and friendly didactic discussions
We aspire to treat everybody equally and value their contributions
Decisions are made based on technical merit and consensus
Code is not the only way to help the project Reviewing pull requests answering questions to help others on mailing lists or issues organizing and teaching tutorials working on the website improving the documentation are all priceless contributions
We abide by the principles of openness respect and consideration of others of the Python Software Foundation httpswwwpythonorgpsfcodeofconduct
In case you experience issues using this package do not hesitate to submit a ticket to the GitHub issue tracker You are also welcome to post feature requests or pull requests
711 Ways to contribute
There are many ways to contribute to scikitlearn with the most common ones being contribution of code or documentation to the project Improving the documentation is no less important than improving the library itself If you find a typo in the documentation or have made improvements do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request Full documentation can be found under the doc directory
But there are many other ways to help In particular answering queries on the issue tracker investigating bugs andreviewing other developers' pull requests are very valuable contributions that decrease the burden on the project maintainers

Another way to contribute is to report issues you're facing and give a "thumbs up" on issues that others reported and that are relevant to you It also helps us if you spread the word reference the project from your blog and articles link to it from your website or simply star to say "I use it"
In case a contributionissue involves changes to the API principles or changes to dependencies or supported versions it must be backed by a Enhancement proposals SLEPs where a SLEP must be submitted as a pullrequest to enhance ment proposals using the SLEP template and follows the decisionmaking process outlined in Scikitlearn governance and decisionmaking
Contributing to related projects
Scikitlearn thrives in an ecosystem of several related projects which also may have relevant issues to work on including smaller projects such as
• scikitlearncontrib
• joblib
• sphinxgallery
• numpydoc
• liacarff
and larger projects
• numpy
• scipy
• matplotlib
• and so on
Look for issues marked "help wanted" or similar Helping these projects may help Scikitlearn too See also Related Projects
712 Submitting a bug report or a feature request
We use GitHub issues to track all bugs and feature requests feel free to open an issue if you have found a bug or wish to see a feature implemented
In case you experience issues using this package do not hesitate to submit a ticket to the Bug Tracker You are also welcome to post feature requests or pull requests
It is recommended to check that your issue complies with the following rules before submitting
• Verify that your issue is not being currently addressed by other issues or pull requests
• If you are submitting an algorithm or feature request please verify that the algorithm fulfills our new algorithm requirements
• If you are submitting a bug report we strongly encourage you to follow the guidelines in How to make a good bug report
How to make a good bug report
When you submit an issue to Github please do your best to follow these guidelines This will make it a lot easier to provide you with good feedback

• The ideal bug report contains a short reproducible code snippet this way anyone can try to reproduce the bug easily see this for more details If your snippet is longer than around 50 lines please link to a gist or a github repo
• If not feasible to include a reproducible snippet please be specific about what estimators andor functions are involved and the shape of the data
• If an exception is raised please provide the full traceback
• Please include your operating system type and version number as well as your Python scikitlearn numpy and scipy versions This information can be found by running the following code snippet
```
 import sklearn
sklearnshowversions
```
Note This utility function is only available in scikitlearn v020 For previous versions one has to explicitly run
```
import platform  printplatformplatform
import sys  printPython sysversion
import numpy  printNumPy numpyversion
import scipy  printSciPy scipyversion
import sklearn  printScikitLearn sklearnversion
```
• Please ensure all code snippets and error messages are formatted in appropriate code blocks See Creating and highlighting code blocks for more details

713 Contributing code

Note To avoid duplicating work it is highly advised that you search through the issue tracker and the PR list If in doubt about duplicated work or if you want to work on a nontrivial feature it’s recommended to first open an issue in the issue tracker to get some feedbacks from core developers

How to contribute

The preferred way to contribute to scikitlearn is to fork the main repository on GitHub then submit a “pull request” PR

1 Create an account on GitHub if you do not already have one
2 Fork the project repository click on the ‘Fork’ button near the top of the page This creates a copy of the code under your account on the GitHub user account For more details on how to fork a repository see this guide
3 Clone your fork of the scikitlearn repo from your GitHub account to your local disk
```
 git clone gitgithubcomYourLoginscikitlearngit
 cd scikitlearn
```
4 Install the development dependencies
```
 pip install cython pytest flake8
```
5 Install scikitlearn in editable mode

```
 pip install editable
```
for more details about advanced installation see the Building from source section
6 Add the upstream remote This saves a reference to the main scikitlearn repository which you can use to keep your repository synchronized with the latest changes
```
 git remote add upstream httpsgithubcomscikitlearnscikitlearngit
```
7 Fetch the upstream and then create a branch to hold your development changes
```
 git fetch upstream
 git checkout b myfeature upstreammaster
```
and start making changes Always use a feature branch It’s good practice to never work on the master branch
8 Develop the feature on your feature branch on your computer using Git to do the version control When you’re done editing add changed files using git add and thengit commit files
```
 git add modifiedfiles
 git commit
```
to record your changes in Git then push the changes to your GitHub account with
```
 git push u origin myfeature
```
9 Follow these instructions to create a pull request from your fork This will send an email to the committers You may want to consider sending an email to the mailing list for more visibility
Note If you are modifying a Cython module you have to rerun step 5 after modifications and before testing them
It is often helpful to keep your local branch synchronized with the latest changes of the main scikitlearn repository
```
 git fetch upstream
 git merge upstreammaster
```
Subsequently you might need to solve the conflicts You can refer to the Git documentation related to resolving merge conflict using the command line
Learning git
The Git documentation and httptrygithubio are excellent resources to get started with git and understanding all of the commands shown here
Pull request checklist
Before a PR can be merged it needs to be approved by two core developers Please prefix the title of your pull request withMRG if the contribution is complete and should be subjected to a detailed review An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed WIP to indicate a work in progress and changed to MRG when it matures WIPs may be useful to indicate you are working on something to avoid duplicated work request broad review of functionality or API or seek collaborators WIPs often benefit from the inclusion of a task list in the PR description

In order to ease the reviewing process we recommend that your contribution complies with the following rules before marking a PR as MRG The bolded ones are especially important
1Give your pull request a helpful title that summarises what your contribution does This title will often become the commit message once merged so it should summarise your contribution for posterity In some cases “Fix ISSUE TITLE” is enough “Fix ISSUE NUMBER” is never a good title
2Make sure your code passes the tests The whole test suite can be run with pytest but it is usually not recommended since it takes a long time It is often enough to only run the test related to your changes for example if you changed something in sklearnlinearmodellogisticpy running the following commands will usually be enough
•pytest sklearnlinearmodellogisticpy to make sure the doctest examples are correct
•pytest sklearnlinearmodelteststestlogisticpy to run the tests specific to the file
•pytest sklearnlinearmodel to test the whole Generalized Linear Models module
•pytest sklearndoclinearmodelrst to make sure the user guide examples are correct
•pytest sklearnteststestcommonpy k LogisticRegression to run all our estimator checks specifically for LogisticRegression if that’s the estimator you changed
There may be other failing tests but they will be caught by the CI so you don’t need to run the whole test suite locally You can read more in Testing and improving test coverage
3Make sure your code is properly commented and documented and make sure the documentation renders properly To build the documentation please refer to our Documentation guidelines The CI will also build the docs please refer to Generated documentation on CircleCI
4Tests are necessary for enhancements to be accepted Bugfixes or new features should be provided with non regression tests These tests verify the correct behavior of the fix or feature In this manner further modifications on the code base are granted to be consistent with the desired behavior In the case of bug fixes at the time of the PR the nonregression tests should fail for the code base in the master branch and pass for the PR code
5Make sure that your PR does not add PEP8 violations On a Unixlike system you can run make flake8diff flake8 pathtofile would work for any system but please avoid reformatting parts of the file that your pull request doesn’t change as it distracts from code review
6 Follow the codingguidelines see below
7 When applicable use the validation tools and scripts in the sklearnutils submodule A list of utility routines available for developers can be found in the Utilities for Developers page
8 Often pull requests resolve one or more other issues or pull requests If merging your pull request means that some other issuesPRs should be closed you should use keywords to create link to them eg Fixes 1234 multiple issuesPRs are allowed as long as each one is preceded by a keyword Upon merging those issuesPRs will automatically be closed by GitHub If your pull request is simply related to some other issuesPRs create a link to them without using the keywords eg See also 1234
9 PRs should often substantiate the change through benchmarks of performance and efficiency or through examples of usage Examples also illustrate the features and intricacies of the library to users Have a look at other examples in the examples directory for reference Examples should demonstrate why the new functionality is useful in practice and if possible compare it to other methods available in scikitlearn
10 New features often need to be illustrated with narrative documentation in the user guide with small code snipets If relevant please also add references in the literature with PDF links when possible
11 The user guide should also include expected time and space complexity of the algorithm and scalability eg “this algorithm can scale to a large number of samples 100000 but does not scale in dimensionality nfeatures is expected to be lower than 100”

You can also check our Code Review Guidelines to get an idea of what reviewers will expect
You can check for common programming errors with the following tools
• Code with a good unittest coverage at least 80 better 100 check with
 pip install pytest pytestcov
 pytest cov sklearn pathtotestsforpackage
see also Testing and improving test coverage
Bonus points for contributions that include a performance analysis with a benchmark script and profiling output please report on the mailing list or on the GitHub issue
Also check out the How to optimize for speed guide for more details on profiling and Cython optimizations
Note The current state of the scikitlearn code base is not compliant with all of those guidelines but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction
Note For two very well documented and more detailed guides on development workflow please pay a visit to the Scipy Development Workflow and the Astropy Workflow for Developers sections
Continuous Integration CI
• Azure pipelines are used for testing scikitlearn on Linux Mac and Windows with different dependencies and settings
• CircleCI is used to build the docs for viewing for linting with flake8 and for testing with PyPy on Linux
Please note that if one of the following markers appear in the latest commit message the following actions are taken
Commit Message
MarkerAction Taken by CI
scipydev Add a Travis build with our dependencies numpy scipy etc develop ment builds
ci skip CI is skipped completely
doc skip Docs are not built
doc quick Docs built but excludes example gallery plots
doc build Docs built including example gallery plots
Stalled pull requests
As contributing a feature can be a lengthy process some pull requests appear inactive but unfinished In such a case taking them over is a great service for the project
A good etiquette to take over is
•Determine if a PR is stalled
–A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors

–To decide whether an inactive PR is stalled ask the contributor if shehe plans to continue working on the PR in the near future Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”
Note that if a PR has received earlier comments on the contribution that have had no reply in a month it is safe to assume that the PR is stalled and to shorten the wait time to one day
After a sprint followup for unmerged PRs opened during sprint will be communicated to participants at the sprint and those PRs will be tagged “sprint” PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders
•Taking over a stalled PR To take over a PR it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one The new PR should be created by pulling from the old one
Issues for New Contributors
New contributors should look for the following tags when looking for issues We strongly recommend that new contributors tackle “easy” issues first this helps the contributor become familiar with the contribution workflow and for the core devs to become acquainted with the contributor besides which we frequently underestimate how easy an issue is to solve
good first issue tag
A great way to start contributing to scikitlearn is to pick an item from the list of good first issues in the issue tracker Resolving these issues allow you to start contributing to the project without much prior knowledge If you have already contributed to scikitlearn you should look at Easy issues instead
Easy tag
If you have already contributed to scikitlearn another great way to contribute to scikitlearn is to pick an item from the list of Easy issues in the issue tracker Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues
help wanted tag
We often use the help wanted tag to mark issues regardless of difficulty Additionally we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off The list of issues with the help wanted tag can be found here
Note that not all issues which need contributors will have this tag
714 Documentation
We are glad to accept any sort of documentation function docstrings reStructuredText documents like this one tutorials etc reStructuredText documents live in the source code repository under the doc directory
You can edit the documentation using any text editor and then generate the HTML output by typing make from thedoc directory Alternatively make html may be used to generate the documentation with the example gallery which takes quite some time The resulting HTML files will be placed in buildhtmlstable and are viewable in a web browser

Building the documentation
First make sure you have properly installed the development version
Building the documentation requires installing some additional packages
pip install sphinx sphinxgallery numpydoc matplotlib Pillow pandas scikitimage
To build the documentation you need to be in the doc folder
cd doc
In the vast majority of cases you only need to generate the full web site without the example gallery
make
The documentation will be generated in the buildhtmlstable directory To also generate the example gallery
you can use
make html
This will run all the examples which takes a while If you only want to generate a few examples you can use
EXAMPLESPATTERNyourregexgoeshere make html
This is particularly useful if you are modifying a few examples
Set the environment variable NOMATHJAX1 if you intend to view the documentation in an offline setting
To build the PDF manual run
make latexpdf
Warning Sphinx version
While we do our best to have the documentation build under as many versions of Sphinx as possible the different
versions tend to behave slightly differently To get the best results you should use the same version as the one we
used on CircleCI Look at this github search to know the exact version
Guidelines for writing documentation
It is important to keep a good compromise between mathematical and algorithmic details and give intuition to the
reader on what the algorithm does
Basically to elaborate on the above it is best to always start with a small paragraph with a handwaving explanation of
what the method does to the data Then it is very helpful to point out why the feature is useful and when it should be
used the latter also including “big O” □□□ complexities of the algorithm as opposed to just rules of thumb as
the latter can be very machinedependent If those complexities are not available then rules of thumb may be provided
instead
Secondly a generated figure from an example as mentioned in the previous paragraph should then be included to
further provide some intuition
Next one or two small code examples to show its use can be added

Next any math and equations followed by references can be added to further the documentation Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do as opposed to how it works “under the hood”
Finally follow the formatting rules below to make it consistently good
• Add “See also” in docstrings for related classesfunctions
• “See also” in docstrings should be one line per reference with a colon and an explanation for example
See also

SelectKBest Select features based on the k highest scores
SelectFpr Select features based on a false positive rate test
• For unwritten formatting rules try to follow existing good works
–For “References” in docstrings see the Silhouette Coefficient sklearnmetrics silhouettescore
• When editing reStructuredText rst files try to keep line length under 80 characters when possible exceptions include links and tables
Generated documentation on CircleCI
When you change the documentation in a pull request CircleCI automatically builds it To view the documentation generated by CircleCI
• navigate to the bottom of your pull request page to see the CI statuses You may need to click on “Show all checks” to see all the CI statuses
• click on the CircleCI status with “doc” in the title
• addartifacts at the end of the URL Note you need to wait for the CircleCI build to finish before being able to look at the artifacts
• once the artifacts are visible navigate to docchangedhtml to see a list of documentation pages that are likely to be affected by your pull request Navigate to docindexhtml to see the full generated html documentation
If you often need to look at the documentation generated by CircleCI eg when reviewing pull requests you may find this tip very handy
715 Testing and improving test coverage
Highquality unit testing is a cornerstone of the scikitlearn development process For this purpose we use the pytest package The tests are functions appropriately named located in tests subdirectories that check the validity of the algorithms and the different options of the code
The full scikitlearn tests can be run using ‘make’ in the root folder Alternatively running ‘pytest’ in a folder will run all the tests of the corresponding subpackages
We expect code coverage of new features to be at least around 90
For guidelines on how to use pytest efficiently see the Useful pytest aliases and flags

Writing matplotlib related tests
Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup The scikitlearn test suite implements a fixture which can be used with matplotlib
pyplot Thepyplot fixture should be used when a test function is dealing with matplotlib matplotlib is a soft dependency and is not required This fixture is in charge of skipping the tests if matplotlib is not installed In addition figures created during the tests will be automatically closed once the test function has been executed
To use this fixture in a test function one needs to pass it as an argument
deftestrequiringmplfixturepyplot
 you can now safely use matplotlib
Workflow to improve test coverage
To test code coverage you need to install the coverage package in addition to pytest
1Run ‘make testcoverage’ The output lists for each file the line numbers that are not tested
2Find a low hanging fruit looking at which lines are not tested write or adapt a test specifically for these lines
3 Loop
Issue Tracker Tags
All issues and pull requests on the GitHub issue tracker should have at least one of the following tags
Bug Crash Something is happening that clearly shouldn’t happen Wrong results as well as unexpected errors from estimators go here
Cleanup Enhancement Improving performance usability consistency
Documentation Missing incorrect or substandard documentations and examples
New Feature Feature requests and pull requests implementing a new feature
There are four other tags to help new contributors
good first issue This issue is ideal for a first contribution to scikitlearn Ask for help if the formulation is unclear If you have already contributed to scikitlearn look at Easy issues instead
Easy This issue can be tackled without much prior experience
Moderate Might need some knowledge of machine learning or the package but is still approachable for someone new to the project
help wanted This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work These issues can range in difficulty and may not be approachable for new contributors Note that not all issues which need contributors will have this tag
716 Coding guidelines
The following are some guidelines on how new code should be written Of course there are special cases and there will be exceptions to these rules However following these rules when submitting new code makes the review easier so new code can be integrated in less time

Uniformly formatted code makes it easier to share code ownership The scikitlearn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented Please read it and follow it

In addition we add the following guidelines

• Use underscores to separate words in non class names nsamples rather than nsamples

• Avoid multiple statements on one line Prefer a line return after a control flow statement iffor

• Use relative imports for references inside scikitlearn

• Unit tests are an exception to the previous rule they should use absolute imports exactly as client code would A corollary is that if sklearnfoo exports a class or function that is implemented in sklearnfoobar baz the test should import it from sklearnfoo

•Please don’t use importin any case It is considered harmful by the official Python recommendations It makes the code harder to read as the origin of symbols is no longer explicitly referenced but most important it prevents using a static analysis tool like pyflakes to automatically find bugs in scikitlearn

• Use the numpy docstring standard in all your docstrings

A good example of code that we like can be found here

Input validation

The module sklearnutils contains various functions for doing input validation and conversion Sometimes npasarray suffices for validation do notusenpasanyarray ornpatleast2d since those let NumPy’s npmatrix through which has a different API eg means dot product on npmatrix but Hadamard product onnpndarray

In other cases be sure to call checkarray on any arraylike argument passed to a scikitlearn API function The exact parameters to use depends mainly on whether and which scipysparse matrices must be accepted

For more information refer to the Utilities for Developers page

Random Numbers

If your code depends on a random number generator do not use numpyrandomrandom or similar routines To ensure repeatability in error checking the routine should accept a keyword randomstate and use this to con struct anumpyrandomRandomState object See sklearnutilscheckrandomstate inUtilities for Developers

Here’s a simple example of code using some of the above guidelines

```
from sklearnutils import checkarray checkrandomstate
defchooserandomsampleX randomstate0

Choose a random point from X
Parameters

X  arraylike shape nsamples nfeatures
array representing the data
randomstate  RandomState or an int seed 0 by default
A random number generator instance to define the state of the
random permutations generator
```

Returns

x numpy array shape nfeatures
A random point selected from X

X checkarrayX
randomstate checkrandomstaterandomstate
i randomstaterandintXshape0
returnXi
If you use randomness in an estimator instead of a freestanding function some additional guidelines apply
First off the estimator should take a randomstate argument to its init with a default value of
None It should store that argument's value unmodified in an attribute randomstate fit can call
checkrandomstate on that attribute to get an actual random number generator If for some reason ran
domness is needed after fit the RNG should be stored in an attribute randomstate The following example
should make this clear
class GaussianNoise BaseEstimator TransformerMixin
This estimator ignores its input and returns random Gaussian noise
It also does not adhere to all scikitlearn conventions
but showcases how to handle randomness

definitself ncomponents100 randomstate None
selfrandomstate randomstate
 the arguments are ignored anyway so we make them optional
deffitself X None yNone
selfrandomstate checkrandomstateselfrandomstate
deftransformself X
nsamples Xshape0
returnselfrandomstaterandnnsamples ncomponents
The reason for this setup is reproducibility when an estimator is fit twice to the same data it should produce an
identical model both times hence the validation in fit notinit
Deprecation
If any publicly accessible method function attribute or parameter is renamed we still support the old one for two
releases and issue a deprecation warning when it is calledpassedaccessed Eg if the function zeroone is re
named tozerooneloss we add the decorator deprecated fromsklearnutils tozeroone and call
zerooneloss from that function
from utils import deprecated
defzeroonelossytrue ypred normalize True
 actual implementation
pass
deprecated Function zeroone was renamed to zerooneloss
in version 013 and will be removed in release 015
Default behavior is changed from normalizeFalse to
normalizeTrue

```
defzerooneytrue ypred normalize False
returnzeroonelossytrue ypred normalize
```
If an attribute is to be deprecated use the decorator deprecated on a property Please note that the property decorator should be placed before the deprecated decorator for the docstrings to be rendered properly Eg renaming an attribute labels toclasses can be done as
```
deprecated Attribute labels was deprecated in version 013 and
will be removed in 015 Use classes instead
property
deflabelsself
returnselfclasses
```
If a parameter has to be deprecated use DeprecationWarning appropriately In the following example k is deprecated and renamed to nclusters
```
import warnings
defexamplefunctionnclusters8 knotused
ifk  notused
warningswarnk was renamed to nclusters in version 013 and
will be removed in 015 DeprecationWarning
nclusters  k
```
When the change is in a class we validate and raise warning in fit
```
import warnings
class ExampleEstimator BaseEstimator
definitself nclusters8 knotused
selfnclusters  nclusters
selfk  k
deffitself X y
ifselfk  notused
warningswarnk was renamed to nclusters in version 013 and
will be removed in 015 DeprecationWarning
selfnclusters  selfk
else
selfnclusters  selfnclusters
```
As in these examples the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed If the deprecation happened in version 0xdev the message should say deprecation occurred in version 0x and the removal will be in 0x2 so that users will have enough time to adapt their code to the new behaviour For example if the deprecation happened in version 018dev the message should say it happened in version 018 and the old behavior will be removed in version 020
In addition a deprecation note should be added in the docstring recalling the same information as the deprecation warning as explained above Use the deprecated directive
```
 deprecated 013
k was renamed to nclusters in version 013 and will be removed
in 015
```
What’s more a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other cases The warning should be caught in all other tests using eg pytestmarkfilterwarnings and there should be no warning in the examples

Change the default value of a parameter
If the default value of a parameter needs to be changed please replace the default value with a specific value eg warn and raiseFutureWarning when users are using the default value In the following example we change the default value of nclusters from 5 to 10 current version is 020
```
import warnings
defexamplefunctionnclusterswarn
ifnclusters warn
warningswarnThe default value of nclusters will change from
5 to 10 in 022 FutureWarning
nclusters 5
```
When the change is in a class we validate and raise warning in fit
```
import warnings
class ExampleEstimator
definitself nclusterswarn
selfnclusters nclusters
deffitself X y
ifselfnclusters warn
warningswarnThe default value of nclusters will change from
5 to 10 in 022 FutureWarning
selfnclusters 5
```
Similar to deprecations the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed The docstring needs to be updated accordingly We need a test which ensures that the warning is raised in relevant cases but not in other cases The warning should be caught in all other tests using eg pytestmarkfilterwarnings and there should be no warning in the examples
Python versions supported
Since scikitlearn 021 only Python 35 and newer is supported
717 Code Review Guidelines
Reviewing code contributed to the project as PRs is a crucial component of scikitlearn development We encourage anyone to start reviewing code of other developers The code review process is often highly educational for everybody involved This is particularly appropriate if it is a feature you would like to use and so can respond critically about whether the PR meets your needs While each pull request needs to be signed off by two core developers you can speed up this process by providing your feedback
Here are a few important aspects that need to be covered in any code review from highlevel questions to a more detailed checklist
• Do we want this in the library Is it likely to be used Do you as a scikitlearn user like the change and intend to use it Is it in the scope of scikitlearn Will the cost of maintaining a new feature be worth its benefits
• Is the code consistent with the API of scikitlearn Are public functionsclassesparameters well named and intuitively designed
• Are all public functionsclasses and their parameters return types and stored attributes named according to scikitlearn conventions and documented clearly

• Is any new functionality described in the userguide and illustrated with examples
• Is every public functionclass tested Are a reasonable set of parameters their values value types and combi
nations tested Do the tests validate that the code is correct ie doing what the documentation says it does If
the change is a bugfix is a nonregression test included Look at this to get started with testing in Python
• Do the tests pass in the continuous integration build If appropriate help the contributor understand why tests
failed
• Do the tests cover every line of code see the coverage report in the build log If not are the lines missing
coverage good exceptions
• Is the code easy to read and low on redundancy Should variable names be improved for clarity or consistency
Should comments be added Should comments be removed as unhelpful or extraneous
• Could the code easily be rewritten to run much more efficiently for relevant settings
• Is the code backwards compatible with previous versions or is a deprecation cycle necessary
• Will the new code add any dependencies on other libraries this is unlikely to be accepted
• Does the documentation render properly see the Documentation section for more details and are the plots
instructive
Standard replies for reviewing includes some frequent comments that reviewers may make
718 APIs of scikitlearn objects
To have a uniform API we try to have a common basic API for all the objects In addition to avoid the proliferation
of framework code we try to adopt simple conventions and limit to a minimum the number of methods an object must
implement
Elements of the scikitlearn API are described more definitively in the Glossary of Common Terms and API Elements
Different objects
The main objects in scikitlearn are one class can implement multiple interfaces
Estimator The base object implements a fit method to learn from data either
estimator estimatorfitdata targets
or
estimator estimatorfitdata
Predictor For supervised learning or some unsupervised problems implements
prediction predictorpredictdata
Classification algorithms usually also offer a way to quantify certainty of a prediction either using
decisionfunction orpredictproba
probability predictorpredictprobadata
Transformer For filtering or modifying the data in a supervised or unsupervised way implements
newdata transformertransformdata

When fitting and transforming can be performed much more efficiently together than separately
implements
newdata transformerfittransformdata
Model A model that can give a goodness of fit measure or a likelihood of unseen data implements higher
is better
score modelscoredata
Estimators
The API has one predominant object the estimator A estimator is an object that fits a model based on some training
data and is capable of inferring some properties on new data It can be for instance a classifier or a regressor All
estimators implement the fit method
estimatorfitX y
All builtin estimators also have a setparams method which sets dataindependent parameters overriding previ
ous parameter values passed to init
All estimators in the main scikitlearn codebase should inherit from sklearnbaseBaseEstimator
Instantiation
This concerns the creation of an object The object's init method might accept constants as arguments that
determine the estimator's behavior like the C constant in SVMs It should not however take the actual training data
as an argument as this is left to the fit method
clf2 SVCC23
clf3 SVC1 2 2 3 1 1 WRONG
The arguments accepted by init should all be keyword arguments with a default value In other words a user
should be able to instantiate an estimator without passing any arguments to it The arguments should all correspond to
hyperparameters describing the model or the optimisation problem the estimator tries to solve These initial arguments
or parameters are always remembered by the estimator Also note that they should not be documented under the
"Attributes" section but rather under the "Parameters" section for that estimator
In addition every keyword argument accepted by init should correspond to an attribute on the instance
Scikitlearn relies on this to find the relevant attributes to set on an estimator when doing model selection
To summarize an init should look like
definitself param11 param22
selfparam1 param1
selfparam2 param2
There should be no logic not even input validation and the parameters should not be changed The corresponding
logic should be put where the parameters are used typically in fit The following is wrong
definitself param11 param22 param33
 WRONG parameters should not be modified
ifparam1 1
param2 1
selfparam1 param1

WRONG the objects attributes should have exactly the name of
the argument in the constructor
selfparam3 param2
The reason for postponing the validation is that the same validation would have to be performed in setparams
which is used in algorithms like GridSearchCV
Fitting
The next thing you will probably want to do is to estimate some parameters in the model This is implemented in the
fit method
Thefit method takes the training data as arguments which can be one array in the case of unsupervised learning
or two arrays in the case of supervised learning
Note that the model is fitted using X and y but the object holds no reference to X and y There are however some
exceptions to this as in the case of precomputed kernels where this data must be stored for use by the predict method
Parameters
X arraylike shape nsamples nfeatures
y array shape nsamples
kwargs optional datadependent parameters
Xshape0 should be the same as yshape0 If this requisite is not met an exception of type ValueError
should be raised
ymight be ignored in the case of unsupervised learning However to make it possible to use the estimator as part of
a pipeline that can mix both supervised and unsupervised transformers even unsupervised estimators need to accept
ayNone keyword argument in the second position that is just ignored by the estimator For the same reason
fitpredict fittransform score andpartialfit methods need to accept a yargument in the second
place if they are implemented
The method should return the object self This pattern is useful to be able to implement quick one liners in an
IPython session such as
ypredicted SVCC100fitXtrain ytrainpredictXtest
Depending on the nature of the algorithm fit can sometimes also accept additional keywords arguments However
any parameter that can have a value assigned prior to having access to the data should be an init keyword
argument fit parameters should be restricted to directly data dependent variables For instance a Gram matrix
or an affinity matrix which are precomputed from the data matrix Xare data dependent A tolerance stopping criterion
tol is not directly data dependent although the optimal value according to some scoring function probably is
Whenfit is called any previous call to fit should be ignored In general calling estimatorfitX1 and
thenestimatorfitX2 should be the same as only calling estimatorfitX2 However this may not
be true in practice when fit depends on some random process see randomstate Another exception to this rule is
when the hyperparameter warmstart is set toTrue for estimators that support it warmstartTrue means
that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization
strategy
Estimated Attributes
Attributes that have been estimated from the data must always have a name ending with trailing underscore for
example the coefficients of some regression estimator would be stored in a coef attribute after fit has been called

The estimated attributes are expected to be overridden when you call fit a second time
Optional Arguments
In iterative algorithms the number of iterations should be specified by an integer called niter
Pairwise Attributes
An estimator that accept Xof shapensamples nsamples and defines a pairwise property equal to True
allows for crossvalidation of the dataset eg when Xis a precomputed kernel matrix Specifically the pairwise
property is used by utilsmetaestimatorssafesplit to slice rows and columns
719 Rolling your own estimator
If you want to implement a new estimator that is scikitlearncompatible whether it is just for you or for contributing it
to scikitlearn there are several internals of scikitlearn that you should be aware of in addition to the scikitlearn API
outlined above You can check whether your estimator adheres to the scikitlearn interface and standards by running
utilsestimatorcheckscheckestimator on the class
```
 from sklearnutilsestimatorchecks import checkestimator
 from sklearnsvm import LinearSVC
checkestimatorLinearSVC  passes
```
The main motivation to make a class compatible to the scikitlearn estimator interface might be that you want
to use it together with model evaluation and selection tools such as modelselectionGridSearchCV and
pipelinePipeline
Before detailing the required interface below we describe two ways to achieve the correct interface more easily
Project template
We provide a project template which helps in the creation of Python packages containing scikitlearn compatible
estimators It provides
• an initial git repository with Python package directory structure
• a template of a scikitlearn estimator
• an initial test suite including use of checkestimator
• directory structures and scripts to compile documentation and example galleries
• scripts to manage continuous integration testing on Linux and Windows
• instructions from getting started to publishing on PyPi
BaseEstimator and mixins
We tend to use “duck typing” so building an estimator which follows the API suffices for compatibility without
needing to inherit from or even import any scikitlearn classes

However if a dependency on scikitlearn is acceptable in your code you can prevent a lot of boilerplate code by deriving a class from BaseEstimator and optionally the mixin classes in sklearnbase For example below is a custom classifier with more examples included in the scikitlearncontrib project template

```
 import numpy as np
 from sklearnbase import BaseEstimator ClassifierMixin
 from sklearnutilsvalidation import checkXy checkarray checkisfitted
 from sklearnutilsmulticlass import uniquelabels
 from sklearnmetrics import euclideandistances
 class TemplateClassifier BaseEstimator ClassifierMixin

 def initself demoparamdemo
 selfdemoparam  demoparam

 def fitself X y

  Check that X and y have correct shape
 X y  checkXyX y
  Store the classes seen during fit
 selfclasses  uniquelabelsy

 selfX  X
 selfy  y
  Return the classifier
 return self

 def predictself X

  Check is fit had been called
 checkisfittedself X y

  Input validation
 X  checkarrayX

 closest  npargmineuclideandistancesX selfX axis1
 return selfyclosest
```

getparams and setparams

All scikitlearn estimators have getparams andsetparams functions The getparams function takes no arguments and returns a dict of the init parameters of the estimator together with their values It must take one keyword argument deep which receives a boolean value that determines whether the method should return the parameters of subestimators for most estimators this can be ignored The default value for deep should be true Thesetparams on the other hand takes as input a dict of the form parameter value and sets the parameter of the estimator using this dict Return value must be estimator itself

While thegetparams mechanism is not essential see Cloning below the setparams function is necessary as it is used to set parameters during grid searches

The easiest way to implement these functions and to get a sensible repr method is to inherit from sklearn baseBaseEstimator If you do not want to make your code dependent on scikitlearn the easiest way to implement the interface is

```
defgetparamsself deep True
 suppose this estimator has parameters alpha and recursive
returnalpha selfalpha recursive selfrecursive
```

defsetparamsself parameters
forparameter value inparametersitems
setattrself parameter value
returnself
Parameters and init
AsmodelselectionGridSearchCV usessetparams to apply parameter setting to estimators it is essen
tial that calling setparams has the same effect as setting parameters using the init method The easiest
and recommended way to accomplish this is to not do any parameter validation in init All logic behind
estimator parameters like translating string arguments into functions should be done in fit
Also it is expected that parameters with trailing arenot to be set inside the init method All and only the
public attributes set by fit have a trailing As a result the existence of parameters with trailing is used to check if
the estimator has been fitted
Cloning
For use with the modelselection module an estimator must support the baseclone function to repli
cate an estimator This can be done by providing a getparams method If getparams is present then
cloneestimator will be an instance of typeestimator on whichsetparams has been called with
clones of the result of estimatorgetparams
Objects that do not provide this method will be deepcopied using the Python standard function copydeepcopy
ifsafeFalse is passed to clone
Pipeline compatibility
For an estimator to be usable together with pipelinePipeline in any but the last step it needs to provide a fit
orfittransform function To be able to evaluate the pipeline on any data but the training set it also needs to
provide atransform function There are no special requirements for the last step in a pipeline except that it has a
fit function All fit andfittransform functions must take arguments X y even if y is not used Similarly
forscore to be usable the last step of the pipeline needs to have a score function that accepts an optional y
Estimator types
Some common functionality depends on the kind of estimator passed For example crossvalidation in
modelselectionGridSearchCV andmodelselectioncrossvalscore defaults to being strat
ified when used on a classifier but not otherwise Similarly scorers for average precision that take a continuous
prediction need to call decisionfunction for classifiers but predict for regressors This distinction be
tween classifiers and regressors is implemented using the estimatortype attribute which takes a string value
It should be classifier for classifiers and regressor for regressors and clusterer for clustering
methods to work as expected Inheriting from ClassifierMixin RegressorMixin orClusterMixin will
set the attribute automatically When a metaestimator needs to distinguish among estimator types instead of checking
estimatortype directly helpers like baseisclassifier should be used
Specific models
Classifiers should accept ytarget arguments to fit that are sequences lists arrays of either strings or integers
They should not assume that the class labels are a contiguous range of integers instead they should store a list of

classes in a classes attribute or property The order of class labels in this attribute should match the order in which predictproba predictlogproba anddecisionfunction return their values The easiest way to achieve this is to put

```
selfclasses y  npuniquey returninverse True
```

infit This returns a new ythat contains class indexes rather than labels in the range 0 nclasses

A classifier's predict method should return arrays containing class labels from classes In a classifier that implements decisionfunction this can be achieved with

```
defpredictself X
D  selfdecisionfunctionX
returnselfclassesnpargmaxD axis1
```

In linear models coefficients are stored in an array called coef and the independent term is stored in intercept sklearnlinearmodelbase contains a few base classes and mixins that implement common linear model patterns

Thesklearnutilsmulticlass module contains useful functions for working with multiclass and multilabel problems

Estimator Tags

Warning The estimator tags are experimental and the API is subject to change

Scikitlearn introduced estimator tags in version 021 These are annotations of estimators that allow programmatic inspection of their capabilities such as sparse matrix support supported output types and supported methods The estimator tags are a dictionary returned by the method gettags These tags are used by the common tests and thesklearnutilsestimatorcheckscheckestimator function to decide what tests to run and what input data is appropriate Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime

The default value of all tags except for Xtypes isFalse These are defined in the BaseEstimator class

The current set of estimator tags are

nondeterministic whether the estimator is not deterministic given a fixed randomstate

requirespositivedata unused for now whether the estimator requires positive X

novalidation whether the estimator skips inputvalidation This is only meant for stateless and dummy transformers

multioutput unused for now whether a regressor supports multitarget outputs or a classifier supports multiclass multioutput

multilabel whether the estimator supports multilabel output

stateless whether the estimator needs access to data for fitting Even though an estimator is stateless it might still need a call to fit for initialization

allownan whether the estimator supports data with missing values encoded as npNaN

poorscore whether the estimator fails to provide a "reasonable" testset score which currently for regression is an R2 of 05 on a subset of the boston housing dataset and for classification an accuracy of 083 on makeblobsnsamples300 randomstate0 These datasets and values are based on current estimators in sklearn and might be replaced by something more systematic

multioutputonly whether estimator supports only multioutput classification or regression

skiptest whether to skip common tests entirely Don’t use this unless you have a very good reason
Xtypes Supported input types for X as list of strings Tests are currently only run if ‘2darray’ is contained in the list signifying that the estimator takes continuous 2d numpy arrays as input The default value is ‘2darray’ Other possible types are string sparse categorical dict 1dlabels and2dlabels
The goal is that in the future the supported input type will determine the data used during testing in particular forstring sparse andcategorical data For now the test for sparse data do not make use of thesparse tag
To override the tags of a child class one must define the moretags method and return a dict with the desired tags eg
class MyMultiOutputEstimator BaseEstimator
defmoretagsself
returnmultioutputonly True
nondeterministic True
In addition to the tags estimators also need to declare any nonoptional parameters to init in the requiredparameters class attribute which is a list or tuple If requiredparameters is only estimator orbaseestimator then the estimator will be instantiated with an instance of LinearDiscriminantAnalysis orRidgeRegression if the estimator is a regressor in the tests The choice of these two models is somewhat idiosyncratic but both should provide robust closedform solutions
7110 Reading the existing code base
Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master Even though we try to write simple code in general understanding the code can seem overwhelming at first given the sheer size of the project Here is a list of tips that may help make this task easier and faster in no particular order
• Get acquainted with the APIs of scikitlearn objects understand what fitpredict transform etc are used for
• Before diving into reading the code of a function class go through the docstrings first and try to get an idea of what each parameter attribute is doing It may also help to stop a minute and think how would I do this myself if I had to
• The trickiest thing is often to identify which portions of the code are relevant and which are not In scikit learn a lot of input checking is performed especially at the beginning of the fitmethods Sometimes only a very small portion of the code is doing the actual job For example looking at the fit method ofsklearnlinearmodelLinearRegression what you’re looking for might just be the call the scipylinalglstsq but it is buried into multiple lines of input checking and the handling of different kinds of parameters
• Due to the use of Inheritance some methods may be implemented in parent classes All estimators inherit at least from BaseEstimator and from a Mixin class eg ClassifierMixin that enables default behaviour depending on the nature of the estimator classifier regressor transformer etc
• Sometimes reading the tests for a given function will give you an idea of what its intended purpose is You can usegit grep see below to find all the tests written for a function Most tests for a specific functionclass are placed under the tests folder of the module
• You’ll often see code looking like this out Parallel delayedsomefunctionparam for param in someiterable This runs somefunction in parallel using Joblib out is then an iterable containing the values returned by somefunction for each call
• We use Cython to write fast code Cython code is located in pyx andpxd files Cython code has a more Clike flavor we use pointers perform manual memory allocation etc Having some minimal experience in C

C is pretty much mandatory here
• Master your tools
–With such a big project being efficient with your favorite editor or IDE goes a long way towards digesting the code base Being able to quickly jump or peek to a functionclassattribute definition helps a lot So does being able to quickly see where a given name is used in a file
–git also has some builtin killer features It is often useful to understand how a file changed over time using eggit blame manual This can also be done directly on GitHub git grep examples is also extremely useful to see every occurrence of a pattern eg a function call or a variable in the code base
72 Developers' Tips and Tricks
721 Productivity and sanitypreserving tips
In this section we gather some useful advice and tools that may increase your qualityoflife when reviewing pull requests running unit tests and so forth Some of these tricks consist of userscripts that require a browser extension such as TamperMonkey or GreaseMonkey to set up userscripts you must have one of these extensions installed enabled and running We provide userscripts as GitHub gists to install them click on the "Raw" button on the gist page
Viewing the rendered HTML documentation for a pull request
We use CircleCI to build the HTML documentation for every pull request To access that documentation instructions are provided in the documentation section of the contributor guide To save you a few clicks we provide a userscript that adds a button to every PR After installing the userscript navigate to any GitHub PR a new button labeled "See CircleCI doc for this PR" should appear in the topright area
Folding and unfolding outdated diffs on pull requests
GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while This userscript provides a shortcut ControlAltP at the time of writing but look at the code to be sure to unfold all such hidden discussions at once so you can catch up
Checking out pull requests as remotetracking branches
In your local fork add to your gitconfig under theremote upstream heading the line
fetch refspull headrefsremotesupstreampr
You may then use git checkout prPRNUMBER to navigate to the code of the pullrequest with the given number Read more in this gist
Display code coverage in pull requests
To overlay the code coverage reports generated by the CodeCov continuous integration consider this browser exten sion The coverage of each line will be displayed as a color background behind the line number

scikitlearn user guide Release 0213
Useful pytest aliases and flags
The full test suite takes fairly long to run For faster iterations it is possibly to select a subset of tests using pytest
selectors In particular one can run a single test based on its node ID
pytest v sklearnlinearmodeltststestlogisticpytestsparsify
or use the k pytest parameter to select tests based on their name For instance
pytest sklearntststestcommonpy v k LogisticRegression
will run all common tests for theLogisticRegression estimator
When a unit test fails the following tricks can make debugging easier
1 The command line argument pytest l instructs pytest to print the local variables when a failure occurs
2 The argument pytest pdb drops into the Python debugger on failure To instead drop into the rich IPython
debuggeripdb you may set up a shell alias to
pytest pdbclsIPythonterminaldebuggerTerminalPdb capture no
Otherpytest options that may become useful include
•xwhich exits on the first failed test
•lf to rerun the tests that failed on the previous run
•ff to rerun all previous tests running the ones that failed first
•sso that pytest does not capture the output of print statements
•tbshort ortbline to control the length of the logs
Since our continuous integration tests will error if DeprecationWarning orFutureWarning aren’t prop
erly caught it is also recommended to run pytest along with the WerrorDeprecationWarning and
WerrorFutureWarning flags
Standard replies for reviewing
It may be helpful to store some of these in GitHub’s saved replies for reviewing
Issue Usage questions
Youre asking a usage question The issue tracker is mainly for bugs and new
‹→features For usage questions it is recommended to try Stack Overflowhttps

‹→mailpythonorgmailmanlistinfoscikitlearn
Issue You’re welcome to update the docs
Please feel free to offer a pull request updating the documentation if you feel
‹→it could be improved
Issue Selfcontained example for bug
Please provide selfcontained example codehttpsstackoverflowcomhelpmcve
‹→including imports and data if possible so that other contributors can just
‹→run it and reproduce your issue Ideally your example code should be minimal

scikitlearn user guide Release 0213
Issue Software versions
To help diagnose your issue please paste the output of
py
import sklearn sklearnshowversions

Thanks
Issue Code blocks
Readability can be greatly improved if you formathttpshelpgithubcom
‹→articlescreatingandhighlightingcodeblocks your code snippets and
‹→complete error messages appropriately For example
python
printsomething

generates
python
printsomething

And
pytb
Traceback most recent call last
File stdin line 1 in module
ImportError No module named hello

generates
pytb
Traceback most recent call last
File stdin line 1 in module
ImportError No module named hello

You can edit your issue descriptions and comments at any time to improve
‹→readability This helps maintainers a lot Thanks
IssueComment Linking to code
Friendly advice for claritys sake you can link to code like thishttps
‹→helpgithubcomarticlescreatingapermanentlinktoacodesnippet
IssueComment Linking to comments
Please use links to comments which make it a lot easier to see what you are
‹→referring to rather than just linking to the issue See thishttps
‹→stackoverflowcomquestions25163598howdoireferenceaspecificissue
‹→commentongithub for more details
PRNEW Better description
Thanks for the pull request Please make the title of the PR descriptive so that
‹→we can easily recall the issue it is resolving You should state what issue or
‹→PR it fixesresolves in the description see herehttpscikitlearnorg
‹→devdevelopersscontributinghtmlcontributingpullrequests
PRNEW Fix

scikitlearn user guide Release 0213
Please use Fix issueNumber in your PR description and you can do it more than
‹→once This way the associated issue gets closed automatically when the PR is
‹→merged For more details look at thishttpsgithubcomblog1506closing
‹→issuesviapullrequests
PRNEW or Issue Maintenance cost
Every feature we include has a maintenance costhttpscikitlearnorgdevfaq
‹→htmlwhyareyousoselectiveonwhatalgorithmsyouincludeinscikitlearn
‹→Our maintainers are mostly volunteers For a new feature to be included we
‹→need evidence that it is often useful and ideally wellestablishedhttp
‹→scikitlearnorgdevfaqhtmlwhataretheinclusioncriteriafornew
‹→algorithms in the literature or in practice That doesnt stop you
‹→implementing it for yourself and publishing it in a separate repository or
‹→even scikitlearncontribhttpsscikitlearncontribgithubio
PRWIP What's needed before merge
Please clarify perhaps as a TODO list in the PR description what work you
‹→believe still needs to be done before it can be reviewed for merge When it is
‹→ready please prefix the PR title with MRG
PRWIP Regression test needed
Please add a nonregression testhttpsenwikipediaorgwikiNonregression
‹→testing that would fail at master but pass in this PR
PRWIP PEP8
You have some PEP8httpswwwpythonorgdevpepspep0008 violations whose
‹→details you can see in the Circle CI lint job It might be worth configuring
‹→your code editor to check for such errors on the fly so you can catch them
‹→before committing
PRMRG Patience
Before merging we generally require two core developers to agree that your pull
‹→request is desirable and ready Please be patienthttpscikitlearnorgdev

‹→yourself and other contributors if applicable with user
PR Don't change unrelated
Please do not change unrelated lines It makes your contribution harder to review
‹→and may introduce merge conflicts to other pull requests

722 Debugging memory errors in Cython with valgrind
While pythonnumpy's builtin memory management is relatively robust it can lead to performance penalties for some routines For this reason much of the highperformance code in scikitlearn in written in cython This performance gain comes with a tradeoff however it is very easy for memory bugs to crop up in cython code especially in situations where that code relies heavily on pointer arithmetic
Memory errors can manifest themselves a number of ways The easiest ones to debug are often segmentation faults and related glibc errors Uninitialized variables can lead to unexpected behavior that is difficult to track down A very useful tool when debugging these sorts of errors is valgrind
Valgrind is a commandline tool that can trace memory errors in a variety of code Follow these steps
1 Install valgrind on your system
2 Download the python valgrind suppression file valgrindpythonsupp
3 Follow the directions in the READMEvalgrind file to customize your python suppressions If you don't you will have spurious output coming related to the python interpreter instead of your own code
4 Run valgrind as follows
valgrind v suppressionsvalgrindpythonsupp python mytestscriptpy
The result will be a list of all the memoryrelated errors which reference lines in the Ccode generated by cython from your pyx file If you examine the referenced lines in the c file you will see comments which indicate the corresponding location in your pyx source file Hopefully the output will give you clues as to the source of your memory error
For more information on valgrind and the array of options it has see the tutorials and documentation on the valgrind web site
73 Utilities for Developers
Scikitlearn contains a number of utilities to help with development These are located in sklearnutils and include tools in a number of categories All the following functions and classes are in the module sklearnutils
Warning These utilities are meant to be used internally within the scikitlearn package They are not guar anteed to be stable between versions of scikitlearn Backports in particular will be removed as the scikitlearn dependencies evolve
731 Validation Tools
These are tools used to check and validate input When you write a function which accepts arrays matrices or sparse matrices as arguments the following should be used when applicable
•assertallfinite Throw an error if array contains NaNs or Infs
•asfloatarray convert input to an array of floats If a sparse matrix is passed a sparse matrix will be returned
•checkarray check that input is a 2D array raise error on sparse matrices Allowed sparse matrix formats can be given optionally as well as allowing 1D or Ndimensional arrays Calls assertallfinite by default

•checkXy check that X and y have consistent length calls checkarray on X and columnor1d on y For multilabel classification or multitarget regression specify multioutputTrue in which case checkarray will be called on y
•indexable check that all input arrays have consistent length and can be sliced or indexed using safeindex This is used to validate input for crossvalidation
•validationcheckmemory checks that input is joblibMemory like which means that it can be converted into a sklearnutilsMemory instance typically a str denoting the cachedir or has the same interface
If your code relies on a random number generator it should never use functions like numpyrandomrandom ornumpyrandomnormal This approach can lead to repeatability issues in unit tests Instead a numpy randomRandomState object should be used which is built from a randomstate argument passed to the class or function The function checkrandomstate below can then be used to create a random number generator object
•checkrandomstate create anprandomRandomState object from a parameter randomstate
–Ifrandomstate isNone ornprandom then a randomlyinitialized RandomState object is re turned
–Ifrandomstate is an integer then it is used to seed a new RandomState object
–Ifrandomstate is aRandomState object then it is passed through
For example
```
 from sklearnutils import checkrandomstate
randomstate  0
randomstate  checkrandomstaterandomstate
randomstaterand4
array05488135  071518937 060276338 054488318
```
When developing your own scikitlearn compatible estimator the following helpers are available
•validationcheckisfitted check that the estimator has been fitted before calling transform predict or similar methods This helper allows to raise a standardized error message across estimator
•validationhasfitparameter check that a given parameter is supported in the fit method of a given estimator
732 Efficient Linear Algebra Array Operations
•extmathrandomizedrangefinder construct an orthonormal matrix whose range approximates the range of the input This is used in extmathrandomizedsvd below
•extmathrandomizedsvd compute the ktruncated randomized SVD This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations It is particularly fast on large matrices on which you wish to extract only a small number of components
•arrayfuncscholeskydelete used insklearnlinearmodellarspath Remove an item from a cholesky factorization
•arrayfuncsminpos used insklearnlinearmodelleastangle Find the minimum of the positive values within an array
•extmathfastlogdet efficiently compute the log of the determinant of a matrix
•extmathdensity efficiently compute the density of a sparse vector

•extmathsafesparsedot dot product which will correctly handle scipysparse inputs If the inputs are dense it is equivalent to numpydot
•extmathweightedmode an extension of scipystatsmode which allows each item to have a real valued weight
•resample Resample arrays or sparse matrices in a consistent way used in shuffle below
•shuffle Shuffle arrays or sparse matrices in a consistent way Used in sklearnclusterkmeans

733 Efficient Random Sampling

•randomsamplewithoutreplacement implements efficient algorithms for sampling nsamples integers from a population of size npopulation without replacement

734 Efficient Routines for Sparse Matrices

Thesklearnutilssparsefuncs cython module hosts compiled extensions to efficiently process scipy sparse data
•sparsefuncsmeanvarianceaxis compute the means and variances along a specified axis of a CSR matrix Used for normalizing the tolerance stopping criterion in sklearnclusterKMeans
•sparsefuncsfastinplacecsrrownormalizel1 andsparsefuncsfast inplacecsrrownormalizel2 can be used to normalize individual sparse samples to unit L1 or L2 norm as done in sklearnpreprocessingNormalizer
•sparsefuncsinplacecsrcolumnscale can be used to multiply the columns of a CSR matrix by a constant scale one scale per column Used for scaling features to unit standard deviation in sklearn preprocessingStandardScaler

735 Graph Routines

•graphsinglesourceshortestpathlength not currently used in scikitlearn Return the shortest path from a single source to all connected nodes on a graph Code is adapted from networkx If this is ever needed again it would be far faster to use a single iteration of Dijkstra’s algorithm from graphshortestpath
•graphshortestpathgraphshortestpath used insklearnmanifoldIsomap Return the shortest path between all pairs of connected points on a directed or undirected graph Both the Floyd Warshall algorithm and Dijkstra’s algorithm are available The algorithm is most efficient when the connectivity matrix is ascipysparsecsrmatrix

736 Testing Functions

•testingassertin testingassertnotin Assertions for container membership Designed for forward compatibility with Nose 10
•testingassertraisemessage Assertions for checking the error raise message
•testingmockmldataurlopen Mocks the urlopen function to fake requests to mldataorg Used in tests ofsklearndatasets
•testingallestimators returns a list of all estimators in scikitlearn to test for consistent behavior and interfaces

737 Multiclass and multilabel utility function
•multiclassismultilabel Helper function to check if the task is a multilabel classification one
•multiclassuniquelabels Helper function to extract an ordered array of unique labels from different formats of target
738 Helper Functions
•genevenslices generator to create npacks of slices going up to n Used in sklearn decompositiondictlearning andsklearnclusterkmeans
•safemask Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices
•safesqr Helper function for unified squaring 2 of arraylikes matrices and sparse matrices
739 Hash Functions
•murmurhash332 provides a python wrapper for the MurmurHash3x8632 C non cryptographic hash function This hash function is suitable for implementing lookup tables Bloom filters Count Min Sketch feature hashing and implicitly defined sparse random projections

```
 from sklearnutils import murmurhash332
murmurhash332some feature seed0  384616559
True
murmurhash332some feature seed0 positive True  3910350737
True
```

Thesklearnutilsmurmurhash module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter
7310 Warnings and Exceptions
•deprecated Decorator to mark a function or class as deprecated
•sklearnexceptionsConvergenceWarning Custom warning to catch convergence problems Used insklearncovariancegraphicallasso
74 How to optimize for speed
The following gives some practical guidelines to help you write efficient code for the scikitlearn project
Note While it is always useful to profile your code so as to check performance assumptions it is also highly recommended to review the literature to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization
Times and times hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple algorithmic tricks or by using another algorithm altogether that is better suited to the problem

The section A simple algorithmic trick warm restarts gives an example of such a trick

741 Python Cython or CC

In general the scikitlearn project emphasizes the readability of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability by the developers

When implementing a new algorithm is thus recommended to start implementing it in Python using Numpy and Scipy by taking care of avoiding looping code using the vectorized idioms of those libraries In practice this means trying to replace any nested for loops by calls to equivalent Numpy array methods The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model It's generally a good idea to consider NumPy and SciPy performance tips httpsscipygithubiooldwikipagesPerformanceTips

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code In this case the recommended strategy is the following

1Profile the Python implementation to find the main bottleneck and isolate it in a dedicated module level func tion This function will be reimplemented as a compiled extension module

2 If there exists a well maintained BSD or MIT CC implementation of the same algorithm that is not too big you can write a Cython wrapper for it and include a copy of the source code of the library in the scikit learn source tree this strategy is used for the classes svmLinearSVC svmSVC andlinearmodel LogisticRegression wrappers for liblinear and libsvm

3 Otherwise write an optimized version of your Python function using Cython directly This strategy is used for thelinearmodelElasticNet andlinearmodelSGDClassifier classes for instance

4Move the Python version of the function in the tests and use it to check that the results of the compiled extension are consistent with the gold standard easy to debug Python version

5 Once the code is optimized not simple bottleneck spottable by profiling check whether it is possible to have coarse grained parallelism that is amenable to multiprocessing by using the joblibParallel class

When using Cython use either

```
 python setuppy buildext i  python setuppy install
```

to generate C files You are responsible for adding ccpp extensions along with build parameters in each submodule setuppy

CC generated files are embedded in distributed stable packages The goal is to make it possible to install scikitlearn stable version on any machine with Python Numpy Scipy and CC compiler

742 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code

Suppose we want to profile the Non Negative Matrix Factorization module of scikitlearn Let us setup a new IPython session and load the digits dataset and as in the Recognizing handwritten digits example

```
In 1 from sklearndecomposition import NMF
In 2 from sklearndatasets import loaddigits
In 3 X  loaddigitsdata
```

Before starting the profiling session and engaging in tentative optimization iterations it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference

```
In 4 timeit NMFncomponents16 tol1e2fitX
1 loops best of 3 17 s per loop
```

To have a look at the overall performance profile using the prun magic command

```
In 5 prun l nmfpy NMFncomponents16 tol1e2fitX
14496 function calls in1682 CPU seconds
Ordered by internal time
List reduced from90 to 9 due to restriction nmfpy
ncalls tottime percall cumtime percall filenamelinenofunction
36 0609 0017 1499 0042 nmfpy151nlssubproblem
1263 0157 0000 0157 0000 nmfpy18pos
1 0053 0053 1681 1681 nmfpy352fittransform
673 0008 0000 0057 0000 nmfpy28norm
1 0006 0006 0047 0047 nmfpy42initializenmf
36 0001 0000 0010 0000 nmfpy36sparseness
30 0001 0000 0001 0000 nmfpy23neg
1 0000 0000 0000 0000 nmfpy337init
1 0000 0000 1681 1681 nmfpy461fit
```

Thetottime column is the most interesting it gives to total time spent executing the code of a given function ignoring the time spent in executing the subfunctions The real total time local code subfunction calls is given by thecumtime column

Note the use of the l nmfpy that restricts the output to lines that contains the “nmfpy” string This is useful to have a quick look at the hotspot of the nmf Python module itself ignoring anything else

Here is the beginning of the output of the same command without the l nmfpy filter

```
In 5 prun NMFncomponents16 tol1e2fitX
16159 function calls in1840 CPU seconds
Ordered by internal time
ncalls tottime percall cumtime percall filenamelinenofunction
2833 0653 0000 0653 0000 numpycoredotblasdot
46 0651 0014 1636 0036 nmfpy151nlssubproblem
1397 0171 0000 0171 0000 nmfpy18pos
2780 0167 0000 0167 0000 method sum of numpyndarray
‹→objects
1 0064 0064 1840 1840 nmfpy352fittransform
1542 0043 0000 0043 0000 method flatten of numpyndarray
‹→objects
337 0019 0000 0019 0000 method all of numpyndarray
‹→objects
2734 0011 0000 0181 0000 fromnumericpy1185sum
2 0010 0005 0010 0005 numpylinalglapacklitedgesdd
748 0009 0000 0065 0000 nmfpy28norm
```

The above results show that the execution is largely dominated by dot products operations delegated to blas Hence there is probably no huge gain to expect by rewriting this code in Cython or CC in this case out of the 17s total execution time almost 07s are spent in compiled code we can consider optimal By rewriting the rest of the Python

code and assuming we could achieve a 1000 boost on this portion which is highly unlikely given the shallowness of the Python loops we would not gain more than a 24x speedup globally
Hence major improvements can only be achieved by algorithmic improvements in this particular example eg trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation
It is however still interesting to check what’s happening inside the nlssubproblem function which is the hotspot if we only consider Python code it takes around 100 of the accumulated time of the module In order to better understand the profile of this specific function let us install lineprofiler and wire it to IPython

```
pip install lineprofiler
```

•Under IPython 013 first create a configuration profile

```
ipython profile create
```

Then register the lineprofiler extension in ipythonprofiledefaultipythonconfigpy

```
cTerminalIPythonAppextensionsappendlineprofiler
cInteractiveShellAppextensionsappendlineprofiler
```

This will register the lprun magic command in the IPython terminal application and the other frontends such as qtconsole and notebook
Now restart IPython and let us use this new toy

```
In 1 from sklearndatasets import loaddigits
In 2 from sklearndecompositionnmf import nlssubproblem NMF
In 3 X  loaddigitsdata
In 4 lprun f nlssubproblem NMFncomponents16 tol1e2fitX

‘→dd

By looking at the top values of the Time column it is really easy to pinpoint the most expensive expressions that would deserve additional care
743 Memory usage profiling
You can analyze in detail the memory usage of any Python code with the help of memoryprofiler First install the latest version
 pip install U memoryprofiler
Then setup the magics in a manner similar to lineprofiler
•Under IPython 011 first create a configuration profile
 ipython profile create
Then register the extension in ipythonprofiledefaultipythonconfigpy alongside the
line profiler
cTerminalIPythonAppextensionsappendmemoryprofiler
cInteractiveShellAppextensionsappendmemoryprofiler
This will register the memit andmprun magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook
mprun is useful to examine linebyline the memory usage of key functions in your program It is very similar to lprun discussed in the previous section For example from the memoryprofilerexamples directory
In 1from example import myfunc
In 2 mprun f myfunc myfunc
Filename examplepy
Line Mem usage Increment Line Contents

3 profile
4 597 MB 000 MB defmyfunc

5 1361 MB 764 MB a 1 106
6 16620 MB 15259 MB b 2 2107
7 1361 MB 15259 MB delb
8 1361 MB 000 MB returna
Another useful magic that memoryprofiler defines ismemit which is analogous to timeit It can be used as follows
In 1 import numpy as np
In 2 memit npzeros1e7
maximum of 3 76402344 MB per loop
For more details see the docstrings of the magics using memit andmprun
744 Performance tips for the Cython developer
If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation eg for loops over vector components nested evaluation of conditional expression scalar arithmetic it is probably adequate to extract the hotspot portion of the code as a standalone function in a pyx file add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module
The official documentation available at httpdocscythonorg contains a tutorial and reference guide for developing such a module In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikitlearn project
TODO html report type declarations bound checks division by zero checks memory alignment direct blas calls
• httpswwwyoutubecomwatchvgMvkiQgOW8
• httpconferencescipyorgproceedingsSciPy2009paper1
• httpconferencescipyorgproceedingsSciPy2009paper2
Using OpenMP
Since scikitlearn can be built without OpenMP support it’s necessary to protect each direct call to OpenMP This can be done using the following syntax
 importing OpenMP
IF SKLEARNOPENMPSUPPORTED
cimport openmp
 calling OpenMP
IF SKLEARNOPENMPSUPPORTED
maxthreads openmpompgetmaxthreads
ELSE
maxthreads 1
Note Protecting the parallel loop prange is already done by cython

745 Profiling compiled extensions
When working with compiled extensions written in CC with a wrapper or directly as Cython extension the default Python profiler is useless we need a dedicated tool to introspect what’s happening inside the compiled extension it self
Using yep and gperftools
Easy profiling without special compilation options use yep
• httpspypiorgprojectyep
• httpfabianpnetblog2011aprofilerforpythonextensions
Using gprof
In order to profile compiled Python extensions one could use gprof after having recompiled the project with gcc pg and using the pythondbg variant of the interpreter on debian ubuntu however this approach requires to also havenumpy andscipy recompiled with pg which is rather complicated to get working
Fortunately there exist two alternative profilers that don’t require you to recompile everything
Using valgrind callgrind kcachegrind
kcachegrind
yep can be used to create a profiling report kcachegrind provides a graphical environment to visualize this report
 Run yep to profile some python script
python m yep c myfilepy
 open myfilepycallgrin with kcachegrind
kcachegrind myfilepyprof
Noteyep can be executed with the argument lines orlto compile a profiling report ‘line by line’
746 Multicore parallelism using joblibParallel
TODO give a simple teaser example here
Checkout the official joblib documentation
• httpsjoblibreadthedocsio
747 A simple algorithmic trick warm restarts
See the glossary entry for warmstart

75 Advanced installation instructions
There are different ways to get scikitlearn installed
•Install an official release This is the best approach for most users It will provide a stable version and prebuild packages are available for most platforms
• Install the version of scikitlearn provided by your operating system or Python distribution This is a quick option for those who have operating systems that distribute scikitlearn It might not provide the latest release version
•Building the package from source This is best for users who want the latestandgreatest features and aren’t afraid of running brandnew code This document describes how to build from source
Note If you wish to contribute to the project you need to install the latest development version
751 Installing nightly builds
The continuous integration servers of the scikitlearn project build test and upload wheel packages for the most recent Python version on a nightly basis to help users test bleeding edge features or bug fixes
pip install pre f httpssklearnnightlyscdn8secureraxcdncom scikitlearn
752 Building from source
In the vast majority of cases building scikitlearn for development purposes can be done with
pip install cython pytest flake8
Then in the main repository
pip install editable
Please read below for details and more advanced instructions
Dependencies
Scikitlearn requires
• Python 35
• NumPy 111
• SciPy 017
• Joblib 011
Note For installing on PyPy PyPy3v510 Numpy 1140 and scipy 110 are required For PyPy only installa tion instructions with pip apply
Building Scikitlearn also requires
• Cython 0285

• OpenMP
Note It is possible to build scikitlearn without OpenMP support by setting the SKLEARNNOOPENMP environ
ment variable before cythonization This is not recommended since it will force some estimators to run in sequential
mode and their njobs parameter will be ignored
Running tests requires
• pytest 330
Some tests also require pandas
Retrieving the latest code
We use Git for version control and GitHub for hosting our main repository
You can check out the latest sources with the command
git clone gitgithubcomscikitlearnscikitlearngit
If you want to build a stable version you can git checkout VERSION to get the code for that particular
version or download an zip archive of the version from github
Once you have all the build requirements installed see below for details you can build and install the package in the
following way
If you run the development version it is cumbersome to reinstall the package each time you update the sources
Therefore it’s recommended that you install in editable mode which allows you to edit the code inplace This builds
the extension in place and creates a link to the development directory see the pip docs
pip install editable
Note This is fundamentally similar to using the command python setuppy develop see the setuptool
docs It is however preferred to use pip
Note You will have to rerun
pip install editable
every time the source code of a compiled extension is changed for instance when switching branches or pulling
changes from upstream Compiled extensions are Cython files ending in pyx orpxd
On Unixlike systems you can equivalently type make in from the toplevel folder Have a look at the Makefile
for additional utilities
Mac OSX
The default C compiler Appleclang on Mac OSX does not directly support OpenMP The first solution to build
scikitlearn is to install another C compiler such as gcc or llvmclang Another solution is to enable OpenMP support
on the default Appleclang In the following we present how to configure this second option
You first need to install the OpenMP library

brew install libomp
Then you need to set the following environment variables
export CCusrbinclang
export CXXusrbinclang
export CPPFLAGSCPPFLAGS Xpreprocessor fopenmp
export CFLAGSCFLAGS Iusrlocaloptlibompinclude
export CXXFLAGSCXXFLAGS Iusrlocaloptlibompinclude
export LDFLAGSLDFLAGS Lusrlocaloptlibomplib lomp
export DYLDLIBRARYPATHusrlocaloptlibomplib
Finally you can build the package using the standard command
FreeBSD
The clang compiler included in FreeBSD 120 and 112 base systems does not include OpenMP support You need to install theopenmp library from packages or ports
sudo pkg install openmp
This will install header files in usrlocalinclude and libs inusrlocallib Since these directories are not searched by default you can set the environment variables to these locations
export CFLAGSCFLAGS Iusrlocalinclude
export CXXFLAGSCXXFLAGS Iusrlocalinclude
export LDFLAGSLDFLAGS Lusrlocallib lomp
export DYLDLIBRARYPATHusrlocallib
Finally you can build the package using the standard command
For the upcomming FreeBSD 121 and 113 versions OpenMP will be included in the base system and these steps will not be necessary
753 Installing build dependencies
Linux
Installing from source without conda requires you to have installed the scikitlearn runtime dependencies Python development headers and a working CC compiler Under Debianbased operating systems which include Ubuntu
sudo aptget install buildessential python3dev python3setuptools python3pip
and then
pip3 install numpy scipy cython
Note In order to build the documentation and run the example code contains in this documentation you will need matplotlib
pip3 install matplotlib

scikitlearn user guide Release 0213
When precompiled wheels are not avalaible for your architecture you can install the system versions
sudo aptget install cython3 python3numpy python3scipy python3matplotlib
On Red Hat and clones eg CentOS install the dependencies using
sudo yum y install gcc gccc pythondevel numpy scipy
Note To use a high performance BLAS library eg OpenBlas see scipy installation instructions
Windows
To build scikitlearn on Windows you need a working CC compiler in addition to numpy scipy and setuptools
The building command depends on the architecture of the Python interpreter 32bit or 64bit You can check the architecture by running the following in cmd orpowershell console
python c import struct printstructcalcsizeP 8
The above commands assume that you have the Python installation folder in your PATH environment variable
You will need Build Tools for Visual Studio 2017
For 64bit Python configure the build environment with
SET DISTUTILSUSESDK1
CProgram Files x86Microsoft Visual
‘→Studio2017BuildToolsVCAuxiliaryBuild vcvarsallbat x64
And build scikitlearn from this environment
python setuppy install
Replacex64 byx86 to build for 32bit Python
Building binary packages and installers
Thewhl package and exe installers can be built with
pip install wheel
python setuppy bdistwheel bdistwininst b doclogosscikitlearnlogobmp
The resulting packages are generated in the dist folder
Using an alternative compiler
It is possible to use MinGW a port of GCC to Windows OS as an alternative to MSVC for 32bit Python Not that extensions built with mingw32 can be redistributed as reusable packages as they depend on GCC runtime libraries typically not installed on endusers environment
To force the use of a particular compiler pass the compiler flag to the build step

scikitlearn user guide Release 0213
python setuppy build compilermycompiler install
wheremycompiler should be one of mingw32 ormsvc
76 Maintainer coredeveloper information
761 Before a release
1 Update authors table
 cd buildtools make authors cd
and commit
2 Confirm any blockers tagged for the milestone are resolved and that other issues tagged for the milestone can be postponed
3 Ensure the change log and commits correspond within reason and that the change log is reasonably well curated Some tools for these tasks include
•mainttoolssortwhatsnewpy can put what’s new entries into sections
• Themainttoolswhatsmissingsh script may be used to identify pull requests that were merged but likely missing from What’s New
Preparing a bugfixrelease
Since any commits to a released branch eg 0999X will automatically update the web site documentation it is best to develop a bugfix release with a pull request in which 0999X is the base It also allows you to keep track of any tasks towards release with a TO DO list
Most development of the bug fix release and its documentation should happen in master to avoid asynchrony To select commits from master for use in the bug fix version 09993 you can use
 git checkout b release09993 master
 git rebase i 0999X
Then pick the commits for release and resolve any issues and create a pull request with 0999X as base Add a commit updating sklearnversion Additional commits can be cherrypicked into the release0 9993 branch while preparing the release
762 Making a release
1 Update docs
• Edit the docwhatsnewrst file to add release title and commit statistics You can retrieve commit statistics with
 git shortlog s 09933 cut f2 sort ignorecase tr n
‘→sed s gs
• Update the release date in whatsnewrst
• Edit the docindexrst to change the ‘News’ entry of the front page

• Note that these changes should be made in master and cherrypicked into the release branch
2 On the branch for releasing update the version number in sklearninitpy the version variable by removingdevonly when ready to release On master increment the verson in the same place when branching for release
3 Create the tag and push it
```
git tag a 0999
git push gitgithubcomscikitlearnscikitlearngit tags
```
4 Create the source tarball
• Wipe clean your repo
```
git clean xfd
```
• Generate the tarball
```
python setuppy sdist
```
The result should be in the dist folder We will upload it later with the wheels Check that you can install it in a new virtualenv and that the tests pass
5 Update the dependency versions and set BUILDCOMMIT variable to the release tag at httpsgithubcomMacPythonscikitlearnwheels
Once the CI has completed successfully collect the generated binary wheel packages and upload them to PyPI by running the following commands in the scikitlearn source folder checked out at the release tag
```
pip install U wheelhouseuploader twine
python setuppy fetchartifacts
```
6 Check the content of the dist folder it should contain all the wheels along with the source tarball “scikit learnXXXtargz”
Make sure that you do not have developer versions or older versions of the scikitlearn package in that folder
Upload everything at once to httpspypiorg
```
twine upload dist
```
7 For majorminor not bugfix release update the symlink for stable in httpsgithubcomscikitlearn scikitlearngithubio
```
cd tmp
git clone depth 1 nocheckout gitgithubcomscikitlearnscikitlearn
‘→githubiogit
cd scikitlearngithubio
echo stable  gitinfosparsecheckout
git checkout master
ln sf 0999 stable
git push origin master
```
The following GitHub checklist might be helpful in a release PR
- update news andwhats new date in master and release branch
- create tag
- update dependencies andrelease tag at httpsgithubcomMacPythonscikit
‘→learnwheels

twine the wheels to PyPI when thats green
httpsgithubcomscikitlearnscikitlearnreleases draft
confirm bot detected at httpsgithubcomcondaforgescikitlearnfeedstock
‘→andwaitformerge
httpsgithubcomscikitlearnscikitlearnreleases publish
announce on mailing list
regenerate Dash docs httpsgithubcomKapeliDashUserContributionstree
‘→masterdocsetsScikit
763 The scikitlearnorg web site
The scikitlearn web site httpscikitlearnorg is hosted at GitHub but should rarely be updated manually by pushing to the httpsgithubcomscikitlearnscikitlearngithubio repository Most updates can be made by pushing to master for dev or a release branch like 099X from which Circle CI builds and uploads the documentation automatically
764 Travis Cron jobs
From httpsdocstraviscicomusercronjobs Travis CI cron jobs work similarly to the cron utility they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository Cron jobs always fetch the most recent commit on a particular branch and build the project at that state Cron jobs can run daily weekly or monthly which in practice means up to an hour after the selected time span and you cannot set them to run at a specific time
For scikitlearn Cron jobs are used for builds that we do not want to run in each PR As an example the build with the dev versions of numpy and scipy is run as a Cron job Most of the time when this numpydev build fail it is related to a numpy change and not a scikitlearn one so it would not make sense to blame the PR author for the Travis failure
The definition of what gets run in the Cron job is done in the travisyml config file exactly the same way as the other Travis jobs We use a if type cron filter in order for the build to be run only in Cron jobs
The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at httpswwwtravisci orgscikitlearnscikitlearnsettings
765 Experimental features
Thesklearnexperimental module was introduced in 021 and contains experimental features estimators that are subject to change without deprecation cycle
To create an experimental module you can just copy and modify the content of enablehistgradientboostingpy or enableiterativeimputerpy
Note that the public import path must be to a public subpackage like sklearnensemble orsklearnimpute not just apy module Also the private experimental features that are imported must be in a submodulesubpackage of the public subpackage eg sklearnensemblehistgradientboosting orsklearnimpute iterativepy This is needed so that pickles still work in the future when the features aren’t experimental anymore
Please also write basic tests following those in testenablehistgradientboostingpy
Make sure every userfacing code you write explicitly mentions that the feature is experimental and add a noqa comment to avoid pep8related warnings
 To use this experimental feature we need to explicitly ask for it
from sklearnexperimental import enablehistgradientboosting noqa
from sklearnensemble import HistGradientBoostingRegressor
76 Maintainer coredeveloper information 2449

scikitlearn user guide Release 0213
For the docs to render properly please also import enablemyexperimentalfeature indocconfpy
else sphinx won’t be able to import the corresponding modules Note that using from sklearnexperimental
importdoes not work
Note that some experimental classes functions are not included in the sklearnexperimental module
sklearndatasetsfetchopenml
