CHAPTER
ONE
WELCOME TO SCIKITLEARN
11 Installing scikitlearn
Note If you wish to contribute to the project it’s recommended you install the latest development version
111 Installing the latest release
Scikitlearn requires
• Python 35
• NumPy 1110
• SciPy 0170
• joblib 011
Scikitlearn plotting capabilities ie functions start with “ plot ” require Matplotlib 151 Some of the scikit
learn examples might require one or more extra dependencies scikitimage 0123 pandas 0180
Warning Scikitlearn 020 was the last version to support Python 27 and Python 34 Scikitlearn now requires
Python 35 or newer
If you already have a working installation of numpy and scipy the easiest way to install scikitlearn is using pip
pip install U scikitlearn
orconda
conda install scikitlearn
If you have not installed NumPy or SciPy yet you can also install these using conda or pip When using pip please
ensure that binary wheels are used and NumPy and SciPy are not recompiled from source which can happen when
using particular configurations of operating system and hardware such as Linux on a Raspberry Pi Building numpy
and scipy from source can be complex especially on Windows and requires careful configuration to ensure that they
link against an optimized implementation of linear algebra routines Instead use a thirdparty distribution as described
below

scikitlearn user guide Release 0213
If you must install scikitlearn and its dependencies with pip you can install it as scikitlearnalldeps The most common use case for this is in a requirementstxt file used as part of an automated build process for a PaaS application or a Docker image This option is not intended for manual installation from the command line
Note For installing on PyPy PyPy3v510 Numpy 1140 and scipy 110 are required
For installation instructions for more distributions see other distributions For compiling the development version from source or building the package if no distribution is available for your architecture see the Advanced installation instructions
112 Thirdparty Distributions
If you don’t already have a python installation with numpy and scipy we recommend to install either via your package manager or via a python bundle These come with numpy scipy scikitlearn matplotlib and many other helpful scientific and data processing libraries
Available options are
Canopy and Anaconda for all supported platforms
Canopy and Anaconda both ship a recent version of scikitlearn in addition to a large set of scientific python library for Windows Mac OSX and Linux
Anaconda offers scikitlearn as part of its free distribution
Warning To upgrade or uninstall scikitlearn installed with Anaconda or conda youshould not use the pip command Instead
To upgrade scikitlearn
conda update scikitlearn
To uninstall scikitlearn
conda remove scikitlearn
Upgrading with pip install U scikitlearn or uninstalling pip uninstall scikitlearn is likely fail to properly remove files installed by the conda command
pip upgrade and uninstall operations only work on packages installed via pip install
WinPython for Windows
The WinPython project distributes scikitlearn as an additional plugin
12 Frequently Asked Questions
Here we try to give some answers to questions that regularly pop up on the mailing list

121 What is the project name a lot of people get it wrong
scikitlearn but not scikit or SciKit nor scikit learn Also not scikitslearn or scikitslearn which were previously used
122 How do you pronounce the project name
sykit learn sci stands for science
123 Why scikit
There are multiple scikits which are scientific toolboxes built around SciPy You can find a list at httpsscikits appspotcomscikits Apart from scikitlearn another popular one is scikitimage
124 How can I contribute to scikitlearn
SeeContributing Before wanting to add a new algorithm which is usually a major and lengthy undertaking it is recommended to start with known issues Please do not contact the contributors of scikitlearn directly regarding contributing to scikitlearn
125 What's the best way to get help on scikitlearn usage
For general machine learning questions please use Cross Validated with the machinelearning tag
For scikitlearn usage questions please use Stack Overflow with the scikitlearn andpython tags You can alternatively use the mailing list
Please make sure to include a minimal reproduction code snippet ideally shorter than 10 lines that highlights your problem on a toy dataset for instance from sklearndatasets or randomly generated with functions of numpy random with a fixed random seed Please remove any line of code that is not necessary to reproduce your problem The problem should be reproducible by simply copypasting your code snippet in a Python shell with scikitlearn installed Do not forget to include the import statements
More guidance to write good reproduction code snippets can be found at httpsstackoverflowcomhelpmcve
If your problem raises an exception that you do not understand even after googling it please make sure to include the full traceback that you obtain when running the reproduction script
For bug reports or feature requests please make use of the issue tracker on GitHub
There is also a scikitlearn Gitter channel where some users and developers might be found
Please do not email any authors directly to ask for assistance report bugs or for any other issue related to scikitlearn
126 How should I save export or deploy estimators for production
SeeModel persistence

127 How can I create a bunch object
Don’t make a bunch object They are not part of the scikitlearn API Bunch objects are just a way to package some numpy arrays As a scikitlearn user you only ever need numpy arrays to feed your model with data
For instance to train a classifier all you need is a 2D array Xfor the input variables and a 1D array yfor the target variables The array Xholds the features as columns and samples as rows The array ycontains integer values to encode the class membership of each sample in X
128 How can I load my own datasets into a format usable by scikitlearn
Generally scikitlearn works on any numeric data stored as numpy arrays or scipy sparse matrices Other types that are convertible to numeric arrays such as pandas DataFrame are also acceptable
For more information on loading your data files into these usable data structures please refer to loading external datasets
129 What are the inclusion criteria for new algorithms
We only consider wellestablished algorithms for inclusion A rule of thumb is at least 3 years since publication 200 citations and wide use and usefulness A technique that provides a clearcut improvement eg an enhanced data structure or a more efficient approximation technique on a widelyused method will also be considered for inclusion From the algorithms or techniques that meet the above criteria only those which fit well within the current API of scikitlearn that is a fitpredicttransform interface and ordinarily having inputoutput that is a numpy array or sparse matrix are accepted
The contributor should support the importance of the proposed addition with research papers andor implementations in other similar packages demonstrate its usefulness via common usecasesapplications and corroborate performance improvements if any with benchmarks andor plots It is expected that the proposed algorithm should outperform the methods that are already implemented in scikitlearn at least in some areas
Inclusion of a new algorithm speeding up an existing model is easier if
• it does not introduce new hyperparameters as it makes the library more futureproof
• it is easy to document clearly when the contribution improves the speed and when it does not for instance “when nfeatures nsamples”
• benchmarks clearly show a speed up
Also note that your implementation need not be in scikitlearn to be used together with scikitlearn tools You can implement your favorite algorithm in a scikitlearn compatible way upload it to GitHub and let us know We will be happy to list it under Related Projects If you already have a package on GitHub following the scikitlearn API you may also be interested to look at scikitlearncontrib
1210 Why are you so selective on what algorithms you include in scikitlearn
Code is maintenance cost and we need to balance the amount of code we have with the size of the team and add to this the fact that complexity scales non linearly with the number of features The package relies on core developers using their free time to fix bugs maintain code and review contributions Any algorithm that is added needs future attention by the developers at which point the original author might long have lost interest See also What are the inclusion criteria for new algorithms For a great read about longterm maintenance issues in opensource software look at the Executive Summary of Roads and Bridges

1211 Why did you remove HMMs from scikitlearn
SeeWill you add graphical models or sequence prediction to scikitlearn
1212 Will you add graphical models or sequence prediction to scikitlearn
Not in the foreseeable future scikitlearn tries to provide a unified API for the basic tasks in machine learning with pipelines and metaalgorithms like grid search to tie everything together The required concepts APIs algorithms and expertise required for structured learning are different from what scikitlearn has to offer If we started doing arbitrary structured learning we'd need to redesign the whole package and the project would likely collapse under its own weight
There are two project with API similar to scikitlearn that do structured prediction
• pystruct handles general structured learning focuses on SSVMs on arbitrary graph structures with approximate inference defines the notion of sample as an instance of the graph structure
• seqlearn handles sequences only focuses on exact inference has HMMs but mostly for the sake of complete ness treats a feature vector as a sample and uses an offset encoding for the dependencies between feature vectors
1213 Will you add GPU support
No or at least not in the near future The main reason is that GPU support will introduce many software dependencies and introduce platform specific issues scikitlearn is designed to be easy to install on a wide variety of platforms Outside of neural networks GPUs don't play a large role in machine learning today and much larger gains in speed can often be achieved by a careful choice of algorithms
1214 Do you support PyPy
In case you didn't know PyPy is an alternative Python implementation with a builtin justintime compiler Experi mental support for PyPy3v510 has been added which requires Numpy 1140 and scipy 110
1215 How do I deal with string data or trees graphs
scikitlearn estimators assume you'll feed them realvalued feature vectors This assumption is hardcoded in pretty much all of the library However you can feed nonnumerical inputs to estimators in several ways
If you have text documents you can use a term frequency features see Text feature extraction for the builtin text vectorizers For more general feature extraction from any kind of data see Loading features from dicts andFeature hashing
Another common case is when you have nonnumerical data and a custom distance or similarity metric on these data Examples include strings with edit distance aka Levenshtein distance eg DNA or RNA sequences These can be encoded as numbers but doing so is painful and errorprone Working with distance metrics on arbitrary data can be done in two ways
Firstly many estimators take precomputed distancesimilarity matrices so if the dataset is not too large you can compute distances for all pairs of inputs If the dataset is large you can use feature vectors with only one "feature" which is an index into a separate data structure and supply a custom metric function that looks up the actual data in this data structure Eg to use DBSCAN with Levenshtein distances

```
 from leven import levenshtein
 import numpy as np
 from sklearncluster import dbscan
data  ACCTCCTAGAAG ACCTACTAGAAGTT GAATATTAGGCCGA
 def levmetricx y
 i j  intx0 inty0  extract indices
 return levenshteindatai dataj

X  nparangelendatareshape1 1
X
array0
1
2
 We need to specify algoritumbrute as the default assumes
 a continuous feature space
dbscanX metriclevmetric eps5 minsamples2 algorithmbrute

0 1 array 0 0 1
```
This uses the thirdparty edit distance package leven
Similar tricks can be used with some care for tree kernels graph kernels etc
1216 Why do I sometime get a crashfreeze with njobs 1 under OSX or Linux
Several scikitlearn tools such as GridSearchCV andcrossvalscore rely internally on Python's multiprocessing module to parallelize execution onto several Python processes by passing njobs 1 as argument
The problem is that Python multiprocessing does afork system call without following it with an exec system call for performance reasons Many libraries like some versions of Accelerate vecLib under OSX some versions of MKL the OpenMP runtime of GCC nvidia's Cuda and probably many others manage their own internal thread pool Upon a call to fork the thread pool state in the child process is corrupted the thread pool believes it has many threads while only the main thread state has been forked It is possible to change the libraries to make them detect when a fork happens and reinitialize the thread pool in that case we did that for OpenBLAS merged upstream in master since 0210 and we contributed a patch to GCC's OpenMP runtime not yet reviewed
But in the end the real culprit is Python's multiprocessing that doesfork withoutexec to reduce the overhead of starting and using new Python processes for parallel computing Unfortunately this is a violation of the POSIX standard and therefore some software editors like Apple refuse to consider the lack of forksafety in Accelerate vecLib as a bug
In Python 34 it is now possible to configure multiprocessing to use the 'forkserver' or 'spawn' start methods instead of the default 'fork' to manage the process pools To work around this issue when using scikitlearn you can set the JOBLIBSTARTMETHOD environment variable to 'forkserver' However the user should be aware that using the 'forkserver' method prevents joblibParallel to call function interactively defined in a shell session
If you have custom code that uses multiprocessing directly instead of using it via joblib you can enable the 'forkserver' mode globally for your program Insert the following instructions in your main script
```
import multiprocessing
 other imports custom code load data define model
ifname  main
multiprocessingsetstartmethodforkserver
```

call scikitlearn utils with njobs 1 here
You can find more default on the new start methods in the multiprocessing documentation
1217 Why does my job use more cores than specified with njobs under OSX or
Linux
This happens when vectorized numpy operations are handled by libraries such as MKL or OpenBLAS
While scikitlearn adheres to the limit set by njobs numpy operations vectorized using MKL or OpenBLAS will
make use of multiple threads within each scikitlearn job thread or process
The number of threads used by the BLAS library can be set via an environment variable For example to set the
maximum number of threads to some integer value N the following environment variables should be set
• For MKL export MKLNUMTHREADSN
• For OpenBLAS export OPENBLASNUMTHREADSN
1218 Why is there no support for deep or reinforcement learning Will there be
support for deep or reinforcement learning in scikitlearn
Deep learning and reinforcement learning both require a rich vocabulary to define an architecture with deep learning
additionally requiring GPUs for efficient computing However neither of these fit within the design constraints of
scikitlearn as a result deep learning and reinforcement learning are currently out of scope for what scikitlearn seeks
to achieve
You can find more information about addition of gpu support at Will you add GPU support
1219 Why is my pull request not getting any attention
The scikitlearn review process takes a significant amount of time and contributors should not be discouraged by a
lack of activity or review on their pull request We care a lot about getting things right the first time as maintenance
and later change comes at a high cost We rarely release any “experimental” code so all of our contributions will be
subject to high use immediately and should be of the highest quality possible initially
Beyond that scikitlearn is limited in its reviewing bandwidth many of the reviewers and core developers are working
on scikitlearn on their own time If a review of your pull request comes slowly it is likely because the reviewers are
busy We ask for your understanding and request that you not close your pull request or discontinue your work solely
because of this reason
1220 How do I set a randomstate for an entire execution
For testing and replicability it is often important to have the entire execution controlled by a single seed for the pseudo
random number generator used in algorithms that have a randomized component Scikitlearn does not use its own
global random state whenever a RandomState instance or an integer random seed is not provided as an argument it
relies on the numpy global random state which can be set using numpyrandomseed For example to set an
execution’s numpy global random state to 42 one could execute the following in his or her script
```
import numpy as np
nprandomseed42
```

However a global random state is prone to modification by other code during execution Thus the only way to ensure replicability is to pass RandomState instances everywhere and ensure that both estimators and crossvalidation splitters have their randomstate parameter set

1221 Why do categorical variables need preprocessing in scikitlearn compared to other tools

Most of scikitlearn assumes data is in NumPy arrays or SciPy sparse matrices of a single numeric dtype These do not explicitly represent categorical variables at present Thus unlike R's dataframes or pandasDataFrame we require explicit conversion of categorical features to numeric values as discussed in Encoding categorical features See also Column Transformer with Mixed Types for an example of working with heterogeneous eg categorical and numeric data

1222 Why does Scikitlearn not directly work with for example pandasDataFrame

The homogeneous NumPy and SciPy data objects currently expected are most efficient to process for most operations Extensive work would also be needed to support Pandas categorical types Restricting input to homogeneous types therefore reduces maintenance cost and encourages usage of efficient data structures

13 Support

There are several ways to get in touch with the developers

131 Mailing List

• The main mailing list is scikitlearn
• There is also a commit list scikitlearncommits where updates to the main repository and test failures get notified

132 User questions

• Some scikitlearn developers support users on StackOverflow using the scikitlearn tag
• For general theoretical or methodological Machine Learning questions stack exchange is probably a more suitable venue

In both cases please use a descriptive question in the title field eg no "Please help with scikitlearn" as this is not a question and put details on what you tried to achieve what were the expected results and what you observed instead in the details field

Code and data snippets are welcome Minimalistic up to 20 lines long reproduction script very helpful

Please describe the nature of your data and the how you preprocessed it what is the number of samples what is the number and type of features id categorical or numerical and for supervised learning tasks what target are your trying to predict binary multiclass 1 out of nclasses or multilabel kout ofnclasses classification or continuous variable regression

133 Bug tracker
If you think you've encountered a bug please report it to the issue tracker
httpsgithubcomscikitlearnscikitlearnissues
Don't forget to include
• steps or better script to reproduce
• expected outcome
• observed outcome or python or gdb tracebacks
To help developers fix your bug faster please link to a httpsgistgithubcom holding a standalone minimalistic python script that reproduces your bug and optionally a minimalistic subsample of your dataset for instance exported as CSV files usingnumpysavetxt
Note gists are git cloneable repositories and thus you can use git to push datafiles to them
134 IRC
Some developers like to hang out on channel scikitlearn onircfreenodenet
If you do not have an IRC client or are behind a firewall this web client works fine httpswebchatfreenodenet
135 Documentation resources
This documentation is relative to 0213 Documentation for other versions can be found here
Printable pdf documentation for old versions can be found here
14 Related Projects
Projects implementing the scikitlearn estimator API are encouraged to use the scikitlearncontrib template which facilitates best practices for testing and documenting estimators The scikitlearncontrib GitHub organisation also accepts highquality contributions of repositories conforming to this template
Below is a list of sisterprojects extensions and domain specific packages
141 Interoperability and framework enhancements
These tools adapt scikitlearn for use with other technologies or otherwise enhance the functionality of scikitlearn's estimators
Data formats
• sklearnpandas bridge for scikitlearn pipelines and pandas data frame with dedicated transformers
• sklearnxarray provides compatibility of scikitlearn estimators with xarray data structures
AutoML
• automl Automated machine learning for production and analytics built on scikitlearn and related projects
Trains a pipeline wth all the standard machine learning steps Tuned for prediction speed and ease of transfer to production environments
• autosklearn An automated machine learning toolkit and a dropin replacement for a scikitlearn estimator

• TPOT An automated machine learning toolkit that optimizes a series of scikitlearn operators to design a ma
chine learning pipeline including data and feature preprocessors as well as the estimators Works as a dropin
replacement for a scikitlearn estimator
• scikitoptimize A library to minimize very expensive and noisy blackbox functions It implements sev
eral methods for sequential modelbased optimization and includes a replacement for GridSearchCV or
RandomizedSearchCV to do crossvalidated parameter search using any of these strategies
Experimentation frameworks
• REP Environment for conducting datadriven research in a consistent and reproducible way
• ML Frontend provides dataset management and SVM fittingprediction through webbased and programmatic
interfaces
• ScikitLearn Laboratory A commandline wrapper around scikitlearn that makes it easy to run machine learning
experiments with multiple learners and large feature sets
• Xcessiv is a notebooklike application for quick scalable and automated hyperparameter tuning and stacked
ensembling Provides a framework for keeping track of modelhyperparameter combinations
Model inspection and visualisation
• eli5 A library for debugginginspecting machine learning models and explaining their predictions
• mlxtend Includes model visualization utilities
• scikitplot A visualization library for quick and easy generation of common plots in data analysis and machine
learning
• yellowbrick A suite of custom matplotlib visualizers for scikitlearn estimators to support visual feature analysis
model selection evaluation and diagnostics
Model export for production
• onnxmltools Serializes many Scikitlearn pipelines to ONNX for interchange and prediction
• sklearn2pmml Serialization of a wide variety of scikitlearn estimators and transformers into PMML with the
help of JPMMLSkLearn library
• sklearnporter Transpile trained scikitlearn models to C Java Javascript and others
• sklearncompiledtrees Generate a C implementation of the predict function for decision trees and ensembles
trained by sklearn Useful for latencysensitive production environments
142 Other estimators and tasks
Not everything belongs or is mature enough for the central scikitlearn project The following are projects providing
interfaces similar to scikitlearn for additional learning algorithms infrastructures and tasks
Structured learning
• Seqlearn Sequence classification using HMMs or structured perceptron
• HMMLearn Implementation of hidden markov models that was previously part of scikitlearn
• PyStruct General conditional random fields and structured prediction
• pomegranate Probabilistic modelling for Python with an emphasis on hidden Markov models
• sklearncrfsuite Linearchain conditional random fields CRFsuite wrapper with sklearnlike API
Deep neural networks etc
• pylearn2 A deep learning and neural network library build on theano with scikitlearn like interface

• sklearntheano scikitlearn compatible estimators transformers and datasets which use Theano internally
• nolearn A number of wrappers and abstractions around existing neural network libraries
• keras Deep Learning library capable of running on top of either TensorFlow or Theano
• lasagne A lightweight library to build and train neural networks in Theano
• skorch A scikitlearn compatible neural network library that wraps PyTorch

Broad scope

• mlxtend Includes a number of additional estimators as well as model visualization utilities
• sparkitlearn Scikitlearn API and functionality for PySpark's distributed modelling

Other regression and classification

• xgboost Optimised gradient boosted decision tree library
• MLEnsemble Generalized ensemble learning stacking blending subsemble deep ensembles etc
• lightning Fast stateoftheart linear model solvers SDCA AdaGrad SVRG SAG etc
• pyearth Multivariate adaptive regression splines
• Kernel Regression Implementation of NadarayaWatson kernel regression with automatic bandwidth selection
• gplearn Genetic Programming for symbolic regression tasks
• multiisotonic Isotonic regression on multidimensional features
• scikitmultilearn Multilabel classification with focus on label space manipulation
• seglearn Time series and sequence learning using sliding window segmentation

Decomposition and clustering

• lda Fast implementation of latent Dirichlet allocation in Cython which uses Gibbs sampling
to sample from the true posterior distribution scikitlearn's sklearndecomposition
LatentDirichletAllocation implementation uses variational inference to sample from a tractable
approximation of a topic model's posterior distribution
• Sparse Filtering Unsupervised feature learning based on sparsefiltering
• kmodes kmodes clustering algorithm for categorical data and several of its variations
• hdbscan HDBSCAN and Robust Single Linkage clustering algorithms for robust variable density clustering
• spherecluster Spherical Kmeans and mixture of von Mises Fisher clustering routines for data on the unit hyper
sphere

Preprocessing

• categoricalencoding A library of sklearn compatible categorical variable encoders
• imbalancedlearn Various methods to under and oversample datasets

Other packages useful for data analysis and machine learning

• Pandas Tools for working with heterogeneous and columnar data relational queries time series and basic statis
tics
• theano A CPUGPU array processing framework geared towards deep learning research

• statsmodels Estimating and analysing statistical models More focused on statistical tests and less on prediction than scikitlearn
• PyMC Bayesian statistical models and fitting algorithms
• Sacred Tool to help you configure organize log and reproduce experiments
• Seaborn Visualization library based on matplotlib It provides a highlevel interface for drawing attractive statistical graphics
• Deep Learning A curated list of deep learning software libraries

Domain specific packages

• scikitimage Image processing and computer vision in python
• Natural language toolkit nltk Natural language processing and some machine learning
• gensim A library for topic modelling document indexing and similarity retrieval
• NiLearn Machine learning for neuroimaging
• AstroML Machine learning for astronomy
• MSMBuilder Machine learning for protein conformational dynamics time series
• scikitsurprise A scikit for building and evaluating recommender systems

144 Snippets and tidbits

15 About us

151 History

This project was started in 2007 as a Google Summer of Code project by David Cournapeau Later that year Matthieu Brucher started work on this project as part of his thesis

In 2010 Fabian Pedregosa Gael Varoquaux Alexandre Gramfort and Vincent Michel of INRIA took leadership of the project and made the first public release February the 1st 2010 Since then several releases have appeared following a 3 month cycle and a thriving international community has been leading the development

152 Governance

The decision making process and governance structure of scikitlearn is laid out in the governance document

153 Authors

The following people are currently core contributors to scikitlearn’s development and maintenance

Please do not email the authors directly to ask for assistance or report issues Instead please see What’s the best way to ask questions about scikitlearn in the FAQ

See also

The following people have been active contributors in the past but are no longer active in the project
• Alexander Fabisch
• Alexandre Passos
• Angel Soler Gollonet
• Arnaud Joly
• Chris Gorgolewski
• David Cournapeau
• David WardeFarley
• Eduard Duchesnay
• Fabian Pedragosa
• Gilles Louppe
• Jacob Schreiber
• Jake Vanderplas
• Jaques Grobler
• Jarrod Millman
• Kyle Kastner
• Lars Buitinck
• Manoj Kumar
• Mathieu Blondel
• Matthieu Brucher
• Noel Dawe
• Paolo Losi
• Peter Prettenhofer
• Raghav Rajagopalan
• Robert Layton
• Ron Weiss
• Satrajit Ghosh
• Shiqiao Du
• Thouis Ray Jones
• Vincent Dubourg
• Vincent Michel
• Virgile Fritsch
• Wei Li

157 Funding

INRIA actively supports this project It has provided funding for Fabian Pedregosa 20102012 Jaques Grob
ler 20122013 and Olivier Grisel 20132017 to work on this project fulltime It also hosts coding sprints and
other events
ParisSaclay Center for Data Science funded one year
for a developer to work on the project fulltime 20142015 and 50 of the time of Guillaume Lemaitre 2016
2017
NYU MooreSloan Data Science Environment funded An
dreas Mueller 20142016 to work on this project The MooreSloan Data Science Environment also funds sev
eral students to work on the project parttime
Télécom Paris
tech funded Manoj Kumar 2014 Tom Dupré la Tour 2015 Raghav RV 20152017 Thierry Guillemot 2016
2017 and Albert Thomas 2017 to work on scikitlearn
Columbia University funds An
dreas Müller since 2016
Andreas Müller also received a grant to improve scikitlearn
from the Alfred P Sloan Foundation in 2017
The University of

scikitlearn user guide Release 0213
Sydney funds Joel Nothman since July 2017
The Labex Digi
Cosme funded Nicolas Goix 20152016 Tom Dupré la Tour 20152016 and 20172018 Mathurin Massias 2018
2019 to work part time on scikitlearn during their PhDs It also funded a scikitlearn coding sprint in 2015
The following students were sponsored by Google to work on
scikitlearn through the Google Summer of Code program
• 2007 David Cournapeau
• 2011 Vlad Niculae
• 2012 Vlad Niculae Immanuel Bayer
• 2013 Kemal Eren Nicolas Trésegnie
• 2014 Hamzeh Alsalhi Issam Laradji Maheshakya Wijewardena Manoj Kumar
• 2015 Raghav RV Wei Xue
• 2016 Nelson Liu YenChen Lin
It also provided funding for sprints and events around scikitlearn If you would like to participate in the next Google
Summer of code program please see this page
The NeuroDebian project providing Debian packaging and contributions is supported by Dr James V Haxby Dart
mouth College
The PSF helped find and manage funding for our 2011 Granada sprint More information can be found here
tinyclues funded the 2011 international Granada sprint
Donating to the project
If you are interested in donating to the project or to one of our codesprints you can use the Paypal button below or the
NumFOCUS Donations Page if you use the latter please indicate that you are donating for the scikitlearn project
All donations will be handled by NumFOCUS a nonprofitorganization which is managed by a board of Scipy
community members NumFOCUS's mission is to foster scientific computing software in particular in Python As
a fiscal home of scikitlearn it ensures that money is available when needed to keep the project funded and available
while in compliance with tax regulations
The received donations for the scikitlearn project mostly will go towards covering travelexpenses for code sprints as
well as towards the organization budget of the project1
1Regarding the organization budget in particular we might use some of the donated funds to pay for other project expenses such as DNS
hosting or continuous integration services

scikitlearn user guide Release 0213
Notes
The 2013 Paris international sprint
Fig 11 IAP VII19 DYSCO
For more information on this sprint see here
158 Infrastructure support
• We would like to thank Rackspace for providing us with a free Rackspace Cloud account to automatically build the documentation and the example gallery from for the development version of scikitlearn using this tool
• We would also like to thank Shining Panda for free CPU time on their Continuous Integration server
16 Who is using scikitlearn
161 JPMorgan
Scikitlearn is an indispensable part of the Python machine learning toolkit at JPMorgan It is very widely used across all parts of the bank for classification predictive analytics and very many other machine learning tasks Its straightforward API its breadth of algorithms and the quality of its documentation combine to make scikitlearn simultaneously very approachable and very powerful
Stephen Simmons VP Athena Research JPMorgan
16 Who is using scikitlearn 17

162 Spotify

Scikitlearn provides a toolbox with solid implementations of a bunch of stateoftheart models and makes it easy to plug them into existing applications We’ve been using it quite a lot for music recommendations at Spotify and I think it’s the most welldesigned ML package I’ve seen so far

Erik Bernhardsson Engineering Manager Music Discovery Machine Learning Spotify

163 Inria

At INRIA we use scikitlearn to support leadingedge basic research in many teams Parietal for neuroimaging Lear for computer vision Visages for medical image analysis Privatics for security The project is a fantastic tool to address difficult applications of machine learning in an academic environment as it is performant and versatile but all easytouse and well documented which makes it well suited to grad students

Gaël Varoquaux research at Parietal

164 betaworks

Betaworks is a NYCbased startup studio that builds new products grows companies and invests in others Over the past 8 years we’ve launched a handful of social data analyticsdriven services such as Bitly Chartbeat digg and Scale Model Consistently the betaworks data science team uses Scikitlearn for a variety of tasks From exploratory analysis to product development it is an essential part of our toolkit Recent uses are included in digg’s new video recommender system and Poncho’s dynamic heuristic subspace clustering

Gilad Lotan Chief Data Scientist

165 Hugging Face
At Hugging Face we’re using NLP and probabilistic models to generate conversational Artificial intelligences that are fun to chat with Despite using deep neural nets for a few of our NLP tasks scikitlearn is still the breadandbutter of our daily machine learning routine The ease of use and predictability of the interface as well as the straightforward mathematical explanations that are here when you need them is the killer feature We use a variety of scikitlearn models in production and they are also operationally very pleasant to work with
Julien Chaumond Chief Technology Officer
166 Evernote
Building a classifier is typically an iterative process of exploring the data selecting the features the attributes of the data believed to be predictive in some way training the models and finally evaluating them For many of these tasks we relied on the excellent scikitlearn package for Python
Read more
Mark Ayzenshtat VP Augmented Intelligence
167 Télécom ParisTech
At Telecom ParisTech scikitlearn is used for handson sessions and home assignments in introductory and advanced machine learning courses The classes are for undergrads and masters students The great benefit of scikitlearn is its fast learning curve that allows students to quickly start working on interesting and motivating problems

Alexandre Gramfort Assistant Professor
168 Bookingcom
At Bookingcom we use machine learning algorithms for many different applications such as recommending ho
tels and destinations to our customers detecting fraudulent reservations or scheduling our customer service agents
Scikitlearn is one of the tools we use when implementing standard algorithms for prediction tasks Its API and doc
umentations are excellent and make it easy to use The scikitlearn developers do a great job of incorporating state of
the art implementations and new algorithms into the package Thus scikitlearn provides convenient access to a wide
spectrum of algorithms and allows us to readily find the right tool for the right job
Melanie Mueller Data Scientist
169 AWeber
The scikitlearn toolkit is indispensable for the Data Analysis and Management team at AWeber It allows us to do
AWesome stuff we would not otherwise have the time or resources to accomplish The documentation is excellent
allowing new engineers to quickly evaluate and apply many different algorithms to our data The text feature extraction
utilities are useful when working with the large volume of email content we have at AWeber The RandomizedPCA
implementation along with Pipelining and FeatureUnions allows us to develop complex machine learning algorithms
efficiently and reliably
Anyone interested in learning more about how AWeber deploys scikitlearn in a production environment should check
out talks from PyData Boston by AWeber's Michael Becker available at httpsgithubcommdbeckerpydata2013
Michael Becker Software Engineer Data Analysis and Management Ninjas
1610 Yhat
The combination of consistent APIs thorough documentation and top notch implementation make scikitlearn our
favorite machine learning package in Python scikitlearn makes doing advanced analysis in Python accessible to
anyone At Yhat we make it easy to integrate these models into your production applications Thus eliminating the
unnecessary dev time encountered productionizing analytical work
Greg Lamp Cofounder Yhat

1611 Rangespan

The Python scikitlearn toolkit is a core tool in the data science group at Rangespan Its large collection of well documented models and algorithms allow our team of data scientists to prototype fast and quickly iterate to find the right solution to our learning problems We find that scikitlearn is not only the right tool for prototyping but its careful and well tested implementation give us the confidence to run scikitlearn models in production

Jurgen Van Gael Data Science Director at Rangespan Ltd

1612 Birchbox

At Birchbox we face a range of machine learning problems typical to Ecommerce product recommendation user clustering inventory prediction trends detection etc Scikitlearn lets us experiment with many models especially in the exploration phase of a new project the data can be passed around in a consistent way models are easy to save and reuse updates keep us informed of new developments from the pattern discovery research community Scikitlearn is an important tool for our team built the right way in the right language

Thierry BertinMahieux Birchbox Data Scientist

1613 Bestofmedia Group

Scikitlearn is our 1 toolkit for all things machine learning at Bestofmedia We use it for a variety of tasks eg spam fighting ad click prediction various ranking models thanks to the varied stateoftheart algorithm implementations packaged into it In the lab it accelerates prototyping of complex pipelines In production I can say it has proven to be robust and efficient enough to be deployed for business critical components

Eustache Diemert Lead Scientist Bestofmedia Group

16 Who is using scikitlearn 21

1614 Changeorg

At changeorg we automate the use of scikitlearn’s RandomForestClassifier in our production systems to drive email targeting that reaches millions of users across the world each week In the lab scikitlearn’s easeofuse performance and overall variety of algorithms implemented has proved invaluable in giving us a single reliable source to turn to for our machinelearning needs

Vijay Ramesh Software Engineer in Datascience at Changeorg

1615 PHIMECA Engineering

At PHIMECA Engineering we use scikitlearn estimators as surrogates for expensivetoevaluate numerical models mostly but not exclusively finiteelement mechanical models for speeding up the intensive postprocessing operations involved in our simulationbased decision making framework Scikitlearn’s fitpredict API together with its efficient crossvalidation tools considerably eases the task of selecting the bestfit estimator We are also using scikitlearn for illustrating concepts in our training sessions Trainees are always impressed by the easeofuse of scikitlearn despite the apparent theoretical complexity of machine learning

Vincent Dubourg PHIMECA Engineering PhD Engineer

1616 HowAboutWe

At HowAboutWe scikitlearn lets us implement a wide array of machine learning techniques in analysis and in pro duction despite having a small team We use scikitlearn’s classification algorithms to predict user behavior enabling us to for example estimate the value of leads from a given traffic source early in the lead’s tenure on our site Also our

users’ profiles consist of primarily unstructured data answers to openended questions so we use scikitlearn’s fea ture extraction and dimensionality reduction tools to translate these unstructured data into inputs for our matchmaking system
Daniel Weitzenfeld Senior Data Scientist at HowAboutWe
1617 PeerIndex
At PeerIndex we use scientific methodology to build the Influence Graph a unique dataset that allows us to identify who’s really influential and in which context To do this we have to tackle a range of machine learning and predic tive modeling problems Scikitlearn has emerged as our primary tool for developing prototypes and making quick progress From predicting missing data and classifying tweets to clustering communities of social media users scikit learn proved useful in a variety of applications Its very intuitive interface and excellent compatibility with other python tools makes it and indispensable tool in our daily research efforts
Ferenc Huszar Senior Data Scientist at Peerindex
1618 DataRobot
DataRobot is building next generation predictive analytics software to make data scientists more productive and scikitlearn is an integral part of our system The variety of machine learning techniques in combination with the solid implementations that scikitlearn offers makes it a onestopshopping library for machine learning in Python Moreover its consistent API welltested code and permissive licensing allow us to use it in a production environment Scikitlearn has literally saved us years of work we would have had to do ourselves to bring our product to market
Jeremy Achin CEO Cofounder DataRobot Inc
1619 OkCupid
We’re using scikitlearn at OkCupid to evaluate and improve our matchmaking system The range of features it has especially preprocessing utilities means we can use it for a wide variety of projects and it’s performant enough to handle the volume of data that we need to sort through The documentation is really thorough as well which makes the library quite easy to use
David Koh Senior Data Scientist at OkCupid
16 Who is using scikitlearn 23

1620 Lovely
At Lovely we strive to deliver the best apartment marketplace with respect to our users and our listings From understanding user behavior improving data quality and detecting fraud scikitlearn is a regular tool for gathering insights predictive modeling and improving our product The easytoread documentation and intuitive architecture of the API makes machine learning both explorable and accessible to a wide range of python developers I’m constantly recommending that more developers and scientists try scikitlearn
Simon Frid Data Scientist Lead at Lovely
1621 Data Publica
Data Publica builds a new predictive sales tool for commercial and marketing teams called CRadar We extensively use scikitlearn to build segmentations of customers through clustering and to predict future customers based on past partnerships success or failure We also categorize companies using their website communication thanks to scikitlearn and its machine learning algorithm implementations Eventually machine learning makes it possible to detect weak signals that traditional tools cannot see All these complex tasks are performed in an easy and straightforward way thanks to the great quality of the scikitlearn framework
Guillaume Lebourgeois Samuel Charron Data Scientists at Data Publica
1622 Machinalis
Scikitlearn is the cornerstone of all the machine learning projects carried at Machinalis It has a consistent API a wide selection of algorithms and lots of auxiliary tools to deal with the boilerplate We have used it in production en vironments on a variety of projects including clickthrough rate prediction information extraction and even counting sheep
In fact we use it so much that we’ve started to freeze our common use cases into Python packages some of them opensourced like FeatureForge Scikitlearn in one word Awesome
Rafael Carrascosa Lead developer

1623 solido
Scikitlearn is helping to drive Moore’s Law via Solido Solido creates computeraided design tools used by the majority of top20 semiconductor companies and fabs to design the bleedingedge chips inside smartphones auto mobiles and more Scikitlearn helps to power Solido’s algorithms for rareevent estimation worstcase verification optimization and more At Solido we are particularly fond of scikitlearn’s libraries for Gaussian Process models largescale regularized linear regression and classification Scikitlearn has increased our productivity because for many ML problems we no longer need to “roll our own” code This PyData 2014 talk has details
Trent McConaghy founder Solido Design Automation Inc
1624 INFONEA
We employ scikitlearn for rapid prototyping and custommade Data Science solutions within our inmemory based Business Intelligence Software INFONEA® As a welldocumented and comprehensive collection of stateoftheart algorithms and pipelining methods scikitlearn enables us to provide flexible and scalable scientific analysis solutions Thus scikitlearn is immensely valuable in realizing a powerful integration of Data Science technology within self service business analytics
Thorsten Kranz Data Scientist Coma Soft AG
1625 Dataiku
Our software Data Science Studio DSS enables users to create data services that combine ETL with Machine Learning Our Machine Learning module integrates many scikitlearn algorithms The scikitlearn library is a perfect integration with DSS because it offers algorithms for virtually all business cases Our goal is to offer a transparent and flexible tool that makes it easier to optimize time consuming aspects of building a data service preparing data and training machine learning algorithms on all types of data
Florian Douetteau CEO Dataiku
1626 Otto Group
Here at Otto Group one of global Big Five B2C online retailers we are using scikitlearn in all aspects of our daily work from data exploration to development of machine learning application to the productive deployment of those services It helps us to tackle machine learning problems ranging from ecommerce to logistics It consistent APIs enabled us to build the Palladium RESTAPI framework around it and continuously deliver scikitlearn based services
16 Who is using scikitlearn 25

scikitlearn user guide Release 0213
Christian Rammig Head of Data Science Otto Group
1627 Zopa
At Zopa the first ever PeertoPeer lending platform we extensively use scikitlearn to run the business and optimize our users' experience It powers our Machine Learning models involved in credit risk fraud risk marketing and pricing and has been used for originating at least 1 billion GBP worth of Zopa loans It is very well documented powerful and simple to use We are grateful for the capabilities it has provided and for allowing us to deliver on our mission of making money simple and fair
Vlasios Vasileiou Head of Data Science Zopa
1628 MARS
ScikitLearn is integral to the Machine Learning Ecosystem at Mars Whether we're designing better recipes for petfood or closely analysing our cocoa supply chain ScikitLearn is used as a tool for rapidly prototyping ideas and taking them to production This allows us to better understand and meet the needs of our consumers worldwide ScikitLearn's featurerich toolset is easy to use and equips our associates with the capabilities they need to solve the business challenges they face every day
Michael Fitzke Next Generation Technologies Sr Leader Mars Inc
17 Release History
Release notes for current and recent releases are detailed on this page with previous releases linked below
Tip Subscribe to scikitlearn releases on librariesio to be notified when new versions are released
171 Legend for changelogs
•MAJOR FEATURE something big that you couldn't do before
•FEATURE something that you couldn't do before
•EFFICIENCY an existing feature now may not require as much computation or memory
•ENHANCEMENT a miscellaneous minor improvement
•FIX something that previously didn't work as documentated – or according to reasonable expectations – should now work
•API C HANGE you will need to change your code to have the same effect in the future or a feature will be removed in the future

18 Version 0213
July 30 2019
181 Changed models
The following estimators and functions when fit with the same data and parameters may produce different models from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in random sampling procedures
• The v0200 release notes failed to mention a backwards incompatibility in metricsmakescorer whenneedsprobaTrue andytrue is binary Now the scorer function is supposed to accept a 1D ypred ie probability of the positive class shape nsamples instead of a 2D ypred ie shape nsamples 2
182 Changelog
sklearncluster
•FIXFixed a bug in clusterKMeans where computation with initrandom was single threaded for njobs 1 ornjobs 1 12955 by Prabakaran Kumaresshan
•FIXFixed a bug in clusterOPTICS where users were unable to pass float minsamples and minclustersize 14496 by Fabian Klopfer and Hanmin Qin
sklearncompose
•FIXFixed an issue in composeColumnTransformer where using DataFrames whose column order differs between func fit and functransform could lead to silently passing incorrect columns to the remainder transformer 14237 by Andreas Schuderer
sklearndatasets
•FIXdatasetsfetchcaliforniahousing datasetsfetchcovtype datasets fetchkddcup99 datasetsfetcholivettifaces datasetsfetchrcv1 and datasetsfetchspeciesdistributions try to persist the previously cache using the new joblib if the cached data was persisted using the deprecated sklearnexternalsjoblib This behavior is set to be deprecated and removed in v023 14197 by Adrin Jalali
sklearnensemble
•FIX Fix zero division error in HistGradientBoostingClassifier and HistGradientBoostingRegressor 14024 by Nicolas Hug
sklearnimpute
•FIXFixed a bug in imputeSimpleImputer andimputeIterativeImputer so that no errors are thrown when there are missing values in training data 13974 by Frank Hoang

scikitlearn user guide Release 0213
sklearninspection
•FIXFixed a bug in inspectionplotpartialdependence wheretarget parameter was not be
ing taken into account for multiclass problems 14393 by Guillem G Subies
sklearnlinearmodel
•FIXFixed a bug in linearmodelLogisticRegressionCV whererefitFalse would fail de
pending on the multiclass andpenalty parameters regression introduced in 021 14087 by
Nicolas Hug
•FIXCompatibility fix for linearmodelARDRegression and Scipy130 Adapts to upstream
changes to the default pinvh cutoff threshold which otherwise results in poor accuracy in some cases 14067
by Tim Staley
sklearnneighbors
•FIXFixed a bug in neighborsNeighborhoodComponentsAnalysis where the validation of initial
parameters ncomponents maxiter andtol required too strict types 14092 by Jérémie du Boisber
ranger
sklearntree
•FIXFixed bug in treeexporttext when the tree has one feature and a single feature name is passed in
14053 by Thomas Fan
•FIXFixed an issue with plottree where it displayed entropy calculations even for gini criterion in
DecisionTreeClassifiers 13947 by Frank Hoang
19 Version 0212
24 May 2019
191 Changelog
sklearndecomposition
•FIXFixed a bug in crossdecompositionCCA improving numerical stability when Yis close to zero
13903 by Thomas Fan
sklearnmetrics
•FIXFixed a bug in metricspairwiseeuclideandistances where a part of the distance matrix
was left uninstanciated for suffiently large float32 datasets regression introduced in 021 13910 by Jérémie
du Boisberranger

sklearnpreprocessing
•FIXFixed a bug in preprocessingOneHotEncoder where the new drop parameter was not reflected
ingetfeaturenames 13894 by James Myatt
sklearnutilssparsefuncs
•FIXFixed a bug where minmaxaxis would fail on 32bit systems for certain large inputs This
affectspreprocessingMaxAbsScaler preprocessingnormalize andpreprocessing
LabelBinarizer 13741 by Roddy MacSween
110 Version 0211
17 May 2019
This is a bugfix release to primarily resolve some packaging issues in version 0210 It also includes minor docu
mentation improvements and some bug fixes
1101 Changelog
sklearninspection
•FIXFixed a bug in inspectionpartialdependence to only check classifier and not regressor for
the multiclassmultioutput case 14309 by Guillaume Lemaitre
sklearnmetrics
•FIXFixed a bug in metricspairwisedistances where it would raise AttributeError for
boolean metrics when Xhad a boolean dtype and Y None 13864 by Paresh Mathur
•FIXFixed two bugs in metricspairwisedistances whennjobs 1 First it used to return a
distance matrix with same dtype as input even for integer dtype Then the diagonal was not zeros for euclidean
metric when YisX 13877 by Jérémie du Boisberranger
sklearnneighbors
•FIXFixed a bug in neighborsKernelDensity which could not be restored from a pickle if
sampleweight had been used 13772 by Aditya Vyas
111 Version 0210
May 2019

1111 Changed models
The following estimators and functions when fit with the same data and parameters may produce different models from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in random sampling procedures
•discriminantanalysisLinearDiscriminantAnalysis for multiclass classification FIX
•discriminantanalysisLinearDiscriminantAnalysis with ‘eigen’ solver FIX
•linearmodelBayesianRidge FIX
• Decision trees and derived ensembles when both maxdepth andmaxleafnodes are set FIX
•linearmodelLogisticRegression andlinearmodelLogisticRegressionCV with ‘saga’ solver FIX
•ensembleGradientBoostingClassifier FIX
•sklearnfeatureextractiontextHashingVectorizer sklearn featureextractiontextTfidfVectorizer and sklearnfeatureextraction textCountVectorizer FIX
•neuralnetworkMLPClassifier FIX
•svmSVCdecisionfunction and multiclassOneVsOneClassifier decisionfunction FIX
•linearmodelSGDClassifier and any derived classifiers FIX
• Any model using the linearmodelsagsagsolver function with a 0seed includ inglinearmodelLogisticRegression linearmodelLogisticRegressionCV linearmodelRidge andlinearmodelRidgeCV with ‘sag’ solver FIX
•linearmodelRidgeCV when using generalized crossvalidation with sparse inputs FIX
Details are listed in the changelog below
While we are trying to better inform users by providing this information we cannot assure that this list is complete
1112 Known Major Bugs
• The default maxiter forlinearmodelLogisticRegression is too small for many solvers given the defaulttol In particular we accidentally changed the default maxiter for the liblinear solver from 1000 to 100 iterations in 3591 released in version 016 In a future release we hope to choose better default maxiter andtol heuristically depending on the solver see 13317
1113 Changelog
Support for Python 34 and below has been officially dropped
sklearnbase
•API C HANGE The R2 score used when calling score on a regressor will use multioutputuniformaverage from version 023 to keep consistent with metricsr2score This will influence the score method of all the multioutput regressors except for multioutput MultiOutputRegressor 13157 by Hanmin Qin

sklearncalibration
•ENHANCEMENT Added support to bin the data passed into calibrationcalibrationcurve by quan
tiles instead of uniformly between 0 and 1 13086 by Scott Cole
•ENHANCEMENT Allow ndimensional arrays as input for calibrationCalibratedClassifierCV
13485 by William de Vazelhes
sklearncluster
•MAJOR FEATURE A new clustering algorithm clusterOPTICS an algoritm related to cluster
DBSCAN that has hyperparameters easier to set and that scales better by Shane Adrin Jalali Erich Schubert
Hanmin Qin and Assia Benbihi
•FIXFixed a bug where clusterBirch could occasionally raise an AttributeError 13651 by Joel Noth
man
•FIXFixed a bug in clusterKMeans where empty clusters weren't correctly relocated when using sample
weights 13486 by Jérémie du Boisberranger
•API C HANGE Thencomponents attribute in clusterAgglomerativeClustering and
clusterFeatureAgglomeration has been renamed to nconnectedcomponents 13427 by
Stephane Couvreur
•ENHANCEMENT clusterAgglomerativeClustering andclusterFeatureAgglomeration
now accept a distancethreshold parameter which can be used to find the clusters instead of
nclusters 9069 by Vathsala Achar and Adrin Jalali
sklearncompose
•API C HANGE composeColumnTransformer is no longer an experimental feature 13835 by Hanmin
Qin
sklearndatasets
•FIXAdded support for 64bit group IDs and pointers in SVMLight files 10727 by Bryan K Woods
•FIXdatasetsloadsampleimages returns images with a deterministic order 13250 by Thomas
Fan
sklearndecomposition
•ENHANCEMENT decompositionKernelPCA now has deterministic output resolved sign ambiguity in
eigenvalue decomposition of the kernel matrix 13241 by Aurélien Bellet
•FIXFixed a bug in decompositionKernelPCA fittransform now produces
the correct output the same as fittransform in case of nonremoved zero eigenvalues
removezeroeigFalse fitinversetransform was also accelerated by using the same trick
asfittransform to compute the transform of X 12143 by Sylvain Marié
•FIXFixed a bug in decompositionNMF whereinit nndsvd init nndsvda and
init nndsvdar are allowed when ncomponents nfeatures instead ofncomponents
minnsamples nfeatures 11650 by Hossein Pourbozorg and Zijie ZJ Poh

•API C HANGE The default value of the init argument in decomposition
nonnegativefactorization will change from random toNone in version 023 to make it
consistent with decompositionNMF A FutureWarning is raised when the default value is used 12988
by Zijie ZJ Poh
sklearndiscriminantanalysis
•ENHANCEMENT discriminantanalysisLinearDiscriminantAnalysis now preserves
float32 andfloat64 dtypes 8769 and 11000 by Thibault Sejourne
•FIXAChangedBehaviourWarning is now raised when discriminantanalysis
LinearDiscriminantAnalysis is given as parameter ncomponents minnfeatures
nclasses 1 andncomponents is changed to minnfeatures nclasses 1 if so
Previously the change was made but silently 11526 by William de Vazelhes
•FIXFixed a bug in discriminantanalysisLinearDiscriminantAnalysis where the pre
dicted probabilities would be incorrectly computed in the multiclass case 6848 by Agamemnon Krasoulis
andGuillaume Lemaitre
•FIXFixed a bug in discriminantanalysisLinearDiscriminantAnalysis where the pre
dicted probabilities would be incorrectly computed with eigen solver 11727 by Agamemnon Krasoulis
sklearndummy
•FIXFixed a bug in dummyDummyClassifier where thepredictproba method was returning int32
array instead of float64 for the stratified strategy 13266 by Christos Aridas
•FIXFixed a bug in dummyDummyClassifier where it was throwing a dimension mismatch error in
prediction time if a column vector ywithshapen 1 was given at fit time 13545 by Nick Sorros and
Adrin Jalali
sklearnensemble
•MAJOR FEATURE Add two new implementations of gradient boosting trees ensemble
HistGradientBoostingClassifier andensembleHistGradientBoostingRegressor
The implementation of these estimators is inspired by LightGBM and can be orders of magnitude faster than
ensembleGradientBoostingRegressor andensembleGradientBoostingClassifier
when the number of samples is larger than tens of thousands of samples The API of these new estimators
is slightly different and some of the features from ensembleGradientBoostingClassifier and
ensembleGradientBoostingRegressor are not yet supported
These new estimators are experimental which means that their results or their API might change without any
deprecation cycle To use them you need to explicitly import enablehistgradientboosting
 explicitly require this experimental feature
 from sklearnexperimental import enablehistgradientboosting noqa
 now you can import normally from sklearnensemble
 from sklearnensemble import HistGradientBoostingClassifier
12807 by Nicolas Hug
•FEATURE AddensembleVotingRegressor which provides an equivalent of ensemble
VotingClassifier for regression problems 12513 by Ramil Nugmanov and Mohamed Ali Jamaoui

•EFFICIENCY MakeensembleIsolationForest prefer threads over processes when running with njobs 1 as the underlying decision tree fit calls do release the GIL This changes reduces memory usage and communication overhead 12543 by Isaac Storch and Olivier Grisel
•EFFICIENCY MakeensembleIsolationForest more memory efficient by avoiding keeping in memory each tree prediction 13260 by Nicolas Goix
•EFFICIENCY ensembleIsolationForest now uses chunks of data at prediction step thus capping the memory usage 13283 by Nicolas Goix
•EFFICIENCY sklearnensembleGradientBoostingClassifier andsklearnensemble GradientBoostingRegressor now keep the input yasfloat64 to avoid it being copied internally by trees 13524 by Adrin Jalali
•ENHANCEMENT Minimized the validation of X in ensembleAdaBoostClassifier andensemble AdaBoostRegressor 13174 by Christos Aridas
•ENHANCEMENT ensembleIsolationForest now exposes warmstart parameter allowing iterative addition of trees to an isolation forest 13496 by Peter Marko
•FIXThe values of featureimportances in all random forest based models ie ensembleRandomForestClassifier ensembleRandomForestRegressor ensembleExtraTreesClassifier ensembleExtraTreesRegressor ensemble RandomTreesEmbedding ensembleGradientBoostingClassifier andensemble GradientBoostingRegressor now
–sum up to1
–all the single node trees in feature importance calculation are ignored
–in case all trees have only one single node ie a root node feature importances will be an array of all zeros
13636 and 13620 by Adrin Jalali
•FIXFixed a bug in ensembleGradientBoostingClassifier andensemble GradientBoostingRegressor which didn’t support scikitlearn estimators as the initial estimator Also added support of initial estimator which does not support sample weights 12436 by Jérémie du Boisberranger and 12983 by Nicolas Hug
•FIXFixed the output of the average path length computed in ensembleIsolationForest when the input is either 0 1 or 2 13251 by Albert Thomas and joshuakennethjones
•FIXFixed a bug in ensembleGradientBoostingClassifier where the gradients would be incor rectly computed in multiclass classification problems 12715 by Nicolas Hug
•FIXFixed a bug in ensembleGradientBoostingClassifier where validation sets for early stop ping were not sampled with stratification 13164 by Nicolas Hug
•FIXFixed a bug in ensembleGradientBoostingClassifier where the default initial prediction of a multiclass classifier would predict the classes priors instead of the log of the priors 12983 by Nicolas Hug
•FIXFixed a bug in ensembleRandomForestClassifier where thepredict method would error for multiclass multioutput forests models if any targets were strings 12834 by Elizabeth Sander
•FIXFixed a bug in ensemblegradientboostingLossFunction andensemble gradientboostingLeastSquaresError where the default value of learningrate in updateterminalregions is not consistent with the document and the caller functions Note however that directly using these loss functions is deprecated 6463 by movelikeriver
•FIXensemblepartialdependence and consequently the new version sklearninspection partialdependence now takes sample weights into account for the partial dependence computation when the gradient boosting model has been trained with sample weights 13193 by Samuel O Ronsin

scikitlearn user guide Release 0213
•API C HANGE ensemblepartialdependence andensembleplotpartialdependence
are now deprecated in favor of inspectionpartialdependence andinspection
plotpartialdependence 12599 by Trevor Stephens and Nicolas Hug
•FIXensembleVotingClassifier andensembleVotingRegressor were failing during fit in
one of the estimators was set to None andsampleweight was notNone 13779 by Guillaume Lemaitre
•API C HANGE ensembleVotingClassifier andensembleVotingRegressor acceptdrop
to disable an estimator in addition to None to be consistent with other estimators ie pipeline
FeatureUnion andcomposeColumnTransformer 13780 by Guillaume Lemaitre
sklearnexternals
•API C HANGE Deprecated externalssix since we have dropped support for Python 27 12916 by Han
min Qin
sklearnfeatureextraction
•FIXIfinputfile orinputfilename and a callable is given as the analyzer sklearn
featureextractiontextHashingVectorizer sklearnfeatureextractiontext
TfidfVectorizer andsklearnfeatureextractiontextCountVectorizer now read
the data from the files and then pass it to the given analyzer instead of passing the file names or the
file objects to the analyzer 13641 by Adrin Jalali
sklearnimpute
•MAJOR FEATURE AddedimputeIterativeImputer which is a strategy for imputing missing values
by modeling each feature with missing values as a function of other features in a roundrobin fashion 8478
and 12177 by Sergey Feldman and Ben Lawson
The API of IterativeImputer is experimental and subject to change without any deprecation cycle To use them
you need to explicitly import enableiterativeimputer
 from sklearnexperimental import enableiterativeimputer noqa
 now you can import normally from sklearnimpute
 from sklearnimpute import IterativeImputer
•FEATURE TheimputeSimpleImputer andimputeIterativeImputer have a new parameter
addindicator which simply stacks a imputeMissingIndicator transform into the output of
the imputer’s transform That allows a predictive estimator to account for missingness 12583 13601 by
Danylo Baibak
•FIXInimputeMissingIndicator avoid implicit densification by raising an exception if input is sparse
addmissingvalues property is set to 0 13240 by Bartosz Telenczuk
•FIXFixed two bugs in imputeMissingIndicator First when Xis sparse all the nonzero non missing
values used to become explicit False in the transformed data Then when featuresmissingonly
all features used to be kept if there were no missing values at all 13562 by Jérémie du Boisberranger
sklearninspection
new subpackage

•FEATURE Partial dependence plots inspectionplotpartialdependence are now supported for any regressor or classifier provided that they have a predictproba method 12599 by Trevor Stephens and Nicolas Hug

sklearnisotonic

•FEATURE Allow different dtypes such as float32 in isotonicIsotonicRegression 8769 by Vlad Niculae

sklearnlinearmodel

•ENHANCEMENT linearmodelRidge now preserves float32 andfloat64 dtypes 8769 and 11000 by Guillaume Lemaitre and Joan Massich

•FEATURE linearmodelLogisticRegression and linearmodel LogisticRegressionCV now support ElasticNet penalty with the 'saga' solver 11646 by Nicolas Hug

•FEATURE Addedlinearmodellarspathgram which is linearmodellarspath in the sufficient stats mode allowing users to compute linearmodellarspath without providing Xandy 11699 by Kuai Yu

•EFFICIENCY linearmodelmakedataset now preserves float32 andfloat64 dtypes reducing memory consumption in stochastic gradient SAG and SAGA solvers 8769 and 11000 by Nelle Varoquaux Arthur Imbert Guillaume Lemaitre and Joan Massich

•ENHANCEMENT linearmodelLogisticRegression now supports an unregularized objective when penaltynone is passed This is equivalent to setting Cnpinf with l2 regularization Not supported by the liblinear solver 12860 by Nicolas Hug

•ENHANCEMENT sparsecg solver inlinearmodelRidge now supports fitting the intercept ie fitinterceptTrue when inputs are sparse 13336 by Bartosz Telenczuk

•ENHANCEMENT The coordinate descent solver used in Lasso ElasticNet etc now issues a ConvergenceWarning when it completes without meeting the desired toleranbce 11754 and 13397 by Brent Fagan and Adrin Jalali

•FIXFixed a bug in linearmodelLogisticRegression andlinearmodel LogisticRegressionCV with 'saga' solver where the weights would not be correctly updated in some cases 11646 by Tom Dupre la Tour

•FIXFixed the posterior mean posterior covariance and returned regularization parameters in linearmodelBayesianRidge The posterior mean and the posterior covariance were not the ones computed with the last update of the regularization parameters and the returned regularization parameters were not the final ones Also fixed the formula of the log marginal likelihood used to compute the score when computescoreTrue 12174 by Albert Thomas

•FIXFixed a bug in linearmodelLassoLarsIC where user input copyXFalse at instance cre ation would be overridden by default parameter value copyXTrue infit 12972 by Lucio Fernandez Arjona

•FIXFixed a bug in linearmodelLinearRegression that was not returning the same coeffecients and intercepts with fitinterceptTrue in sparse and dense case 13279 by Alexandre Gramfort

•FIXFixed a bug in linearmodelHuberRegressor that was broken when Xwas of dtype bool 13328 by Alexandre Gramfort

•FIXFixed a performance issue of saga andsag solvers when called in a joblibParallel setting with njobs 1 andbackendthreading causing them to perform worse than in the sequential case 13389 by Pierre Glaser
•FIXFixed a bug in linearmodelstochasticgradientBaseSGDClassifier that was not deterministic when trained in a multiclass setting on several threads 13422 by Clément Doumouro
•FIX Fixed bug in linearmodelridgeregression linearmodelRidge andlinearmodelRidgeClassifier that caused unhandled exception for arguments returninterceptTrue andsolverauto default or any other solver different from sag 13363 by Bartosz Telenczuk
•FIXlinearmodelridgeregression will now raise an exception if returninterceptTrue and solver is different from sag Previously only warning was issued 13363 by Bartosz Telenczuk
•FIXlinearmodelridgeregression will choose sparsecg solver for sparse inputs when solverauto andsampleweight is provided previously cholesky solver was selected 13363 by Bartosz Telenczuk
•API C HANGE The use oflinearmodellarspath withXNone while passing Gram is deprecated in version 021 and will be removed in version 023 Use linearmodellarspathgram instead 11699 by Kuai Yu
•API C HANGE linearmodellogisticregressionpath is deprecated in version 021 and will be removed in version 023 12821 by Nicolas Hug
•FIXlinearmodelRidgeCV with generalized crossvalidation now correctly fits an intercept when fitinterceptTrue and the design matrix is sparse 13350 by Jérôme Dockès

sklearnmanifold

•EFFICIENCY Makemanifoldtsnetrustworthiness use an inverted index instead of an npwhere lookup to find the rank of neighbors in the input space This improves efficiency in particular when computed with lots of neighbors andor small datasets 9907 by William de Vazelhes

sklearnmetrics

•FEATURE Added themetricsmaxerror metric and a corresponding maxerror scorer for single output regression 12232 by Krishna Sangeeth
•FEATURE Addmetricsmultilabelconfusionmatrix which calculates a confusion matrix with true positive false positive false negative and true negative counts for each class This facilitates the calculation of setwise metrics such as recall specificity fall out and miss rate 11179 by Shangwu Yao and Joel Nothman
•FEATURE metricsjaccardscore has been added to calculate the Jaccard coefficient as an evalua tion metric for binary multilabel and multiclass tasks with an interface analogous to metricsf1score 13151 by Gaurav Dhingra and Joel Nothman
•FEATURE Addedmetricspairwisehaversinedistances which can be accessed with metricpairwise throughmetricspairwisedistances and estimators Haversine distance was previously available for nearest neighbors calculation 12568 by Wei Xue Emmanuel Arias and Joel Nothman
•EFFICIENCY Fastermetricspairwisedistances with njobs 1 by using a threadbased backend instead of processbased backends 8216 by Pierre Glaser and Romuald Menuet
•EFFICIENCY The pairwise manhattan distances with sparse input now uses the BLAS shipped with scipy instead of the bundled BLAS 12732 by Jérémie du Boisberranger

•ENHANCEMENT Use label accuracy instead of microaverage onmetrics
classificationreport to avoid confusion microaverage is only shown for multilabel or
multiclass with a subset of classes because it is otherwise identical to accuracy 12334 by Emmanuel Arias
Joel Nothman and Andreas Müller
•ENHANCEMENT Addedbeta parameter to metricshomogeneitycompletenessvmeasure and
metricsvmeasurescore to configure the tradeoff between homogeneity and completeness 13607
by Stephane Couvreur and and Ivan Sanchez
•FIXThe metric metricsr2score is degenerate with a single sample and now it returns NaN and raises
exceptionsUndefinedMetricWarning 12855 by Pawel Sendyk
•FIXFixed a bug where metricsbrierscoreloss will sometimes return incorrect result when there's
only one class in ytrue 13628 by Hanmin Qin
•FIXFixed a bug in metricslabelrankingaverageprecisionscore where sampleweight
wasn't taken into account for samples with degenerate labels 13447 by Dan Ellis
•API C HANGE The parameter labels inmetricshammingloss is deprecated in version 021 and will
be removed in version 023 10580 by Reshama Shaikh and Sandra Mitrovic
•FIXThe function metricspairwiseeuclideandistances and therefore several estimators with
metriceuclidean suffered from numerical precision issues with float32 features Precision has
been increased at the cost of a small drop of performance 13554 by Celelibi and Jérémie du Boisberranger
•API C HANGE metricsjaccardsimilarityscore is deprecated in favour of the more consistent
metricsjaccardscore The former behavior for binary and multiclass targets is broken 13151 by
Joel Nothman
sklearnmixture
•FIXFixed a bug in mixtureBaseMixture and therefore on estimators based on it ie mixture
GaussianMixture andmixtureBayesianGaussianMixture wherefitpredict andfit
predict were not equivalent 13142 by Jérémie du Boisberranger
sklearnmodelselection
•FEATURE ClassesGridSearchCV andRandomizedSearchCV now allow for refitcallable to add flex
ibility in identifying the best estimator See Balance model complexity and crossvalidated score 11354 by
Wenhao Zhang Joel Nothman and Adrin Jalali
•ENHANCEMENT ClassesGridSearchCV RandomizedSearchCV and methods crossvalscore
crossvalpredict crossvalidate now print train scores when returntrainscores is
True and verbose 2 Forlearningcurve andvalidationcurve only the latter is required 12613
and 12669 by Marc Torrellas
•ENHANCEMENT Some CV splitter classes and modelselectiontraintestsplit now raise
ValueError when the resulting training set is empty 12861 by Nicolas Hug
•FIXFixed a bug where modelselectionStratifiedKFold shuffles each class's samples with the
samerandomstate makingshuffleTrue ineffective 13124 by Hanmin Qin
•FIXAdded ability for modelselectioncrossvalpredict to handle multilabel and
multioutputmulticlass targets with predictproba type methods 8773 by Stephen Hoover
•FIXFixed an issue in crossvalpredict wheremethodpredictproba returned always 00
when one of the classes was excluded in a crossvalidation fold 13366 by Guillaume Fournier

sklearnmulticlass
•FIXFixed an issue in multiclassOneVsOneClassifierdecisionfunction where the deci
sionfunction value of a given sample was different depending on whether the decisionfunction was evaluated
on the sample alone or on a batch containing this same sample due to the scaling used in decisionfunction
10440 by Jonathan Ohayon
sklearnmultioutput
•FIXFixed a bug in multioutputMultiOutputClassifier where the predictproba method incor
rectly checked for predictproba attribute in the estimator object 12222 by Rebekah Kim
sklearnneighbors
•MAJOR FEATURE AddedneighborsNeighborhoodComponentsAnalysis for metric learning
which implements the Neighborhood Components Analysis algorithm 10058 by William de Vazelhes and
John Chiotellis
•API C HANGE Methods in neighborsNearestNeighbors kneighbors radiusneighbors
kneighborsgraph radiusneighborsgraph now raise NotFittedError rather than
AttributeError when called before fit 12279 by Krishna Sangeeth
sklearnneuralnetwork
•FIXFixed a bug in neuralnetworkMLPClassifier andneuralnetworkMLPRegressor
where the option shuffleFalse was being ignored 12582 by Sam Waterbury
•FIXFixed a bug in neuralnetworkMLPClassifier where validation sets for early stopping were not
sampled with stratification In the multilabel case however splits are still not stratified 13164 by Nicolas Hug
sklearnpipeline
•FEATURE pipelinePipeline can now use indexing notation eg mypipeline01 to extract a
subsequence of steps as another Pipeline instance A Pipeline can also be indexed directly to extract a particular
step egmypipelinesvc rather than accessing namedsteps 2568 by Joel Nothman
•FEATURE Added optional parameter verbose inpipelinePipeline compose
ColumnTransformer andpipelineFeatureUnion and corresponding make helpers for showing
progress and timing of each step 11364 by Baze Petrushev Karan Desai Joel Nothman and Thomas Fan
•ENHANCEMENT pipelinePipeline now supports using passthrough as a transformer with the
same effect as None 11144 by Thomas Fan
•ENHANCEMENT pipelinePipeline implements len and therefore lenpipeline returns the
number of steps in the pipeline 13439 by Lakshya KD
sklearnpreprocessing
•FEATURE preprocessingOneHotEncoder now supports dropping one feature per category with a new
drop parameter 12908 by Drew Johnston
•EFFICIENCY preprocessingOneHotEncoder andpreprocessingOrdinalEncoder now han
dle pandas DataFrames more efficiently 13253 by maikia

•EFFICIENCY MakepreprocessingMultiLabelBinarizer cache class mappings instead of calculat
ing it every time on the fly 12116 by Ekaterina Krivich and Joel Nothman
•EFFICIENCY preprocessingPolynomialFeatures now supports compressed sparse row CSR ma
trices as input for degrees 2 and 3 This is typically much faster than the dense case as it scales with matrix
density and expansion degree on the order of densitydegree and is much much faster than the compressed
sparse column CSC case 12197 by Andrew Nystrom
•EFFICIENCY Speed improvement in preprocessingPolynomialFeatures in the dense case Also
added a new parameter order which controls output order for further speed performances 12251 by Tom
Dupre la Tour
•FIXFixed the calculation overflow when using a float16 dtype with preprocessingStandardScaler
13007 by Raffaello Baluyot
•FIXFixed a bug in preprocessingQuantileTransformer andpreprocessing
quantiletransform to force nquantiles to be at most equal to nsamples Values of nquantiles
larger than nsamples were either useless or resulting in a wrong approximation of the cumulative distribution
function estimator 13333 by Albert Thomas
•API C HANGE The default value of copy inpreprocessingquantiletransform will change from
False to True in 023 in order to make it more consistent with the default copy values of other functions in
preprocessing and prevent unexpected side effects by modifying the value of Xinplace 13459 by Hunter
McGushion
sklearnsvm
•FIXFixed an issue in svmSVCdecisionfunction whendecisionfunctionshapeovr
The decisionfunction value of a given sample was different depending on whether the decisionfunction was
evaluated on the sample alone or on a batch containing this same sample due to the scaling used in deci
sionfunction 10440 by Jonathan Ohayon
sklearntree
•FEATURE Decision Trees can now be plotted with matplotlib using treeplottree without relying on the
dot library removing a hardtoinstall dependency 8508 by Andreas Müller
•FEATURE Decision Trees can now be exported in a human readable textual format using tree
exporttext 6261 by Giuseppe Vettigli
•FEATURE getnleaves andgetdepth have been added to treeBaseDecisionTree
and consequently all estimators based on it including treeDecisionTreeClassifier tree
DecisionTreeRegressor treeExtraTreeClassifier andtreeExtraTreeRegressor
12300 by Adrin Jalali
•FIXTrees and forests did not previously predict multioutput classification targets with string labels despite
accepting them in fit 11458 by Mitar Milutinovic
•FIXFixed an issue with treeBaseDecisionTree and consequently all estimators based
on it including treeDecisionTreeClassifier treeDecisionTreeRegressor tree
ExtraTreeClassifier andtreeExtraTreeRegressor where they used to exceed the given
maxdepth by 1 while expanding the tree if maxleafnodes andmaxdepth were both specified by
the user Please note that this also affects all ensemble methods using decision trees 12344 by Adrin Jalali

sklearnutils
•FEATURE utilsresample now accepts a stratify parameter for sampling according to class distribu
tions 13549 by Nicolas Hug
•API C HANGE Deprecated warnondtype parameter from utilscheckarray andutils
checkXy Added explicit warning for dtype conversion in checkpairwisearrays if themetric
being passed is a pairwise boolean metric 13382 by Prathmesh Savale
Multiple modules
•MAJOR FEATURE Therepr method of all estimators used when calling printestimator
has been entirely rewritten building on Python's pretty printing standard library All parameters are printed
by default but this can be altered with the printchangedonly option insklearnsetconfig
11705 by Nicolas Hug
•MAJOR FEATURE Add estimators tags these are annotations of estimators that allow programmatic inspection
of their capabilities such as sparse matrix support supported output types and supported methods Estimator
tags also determine the tests that are run on an estimator when checkestimator is called Read more in
theUser Guide 8022 by Andreas Müller
•EFFICIENCY Memory copies are avoided when casting arrays to a different dtype in multiple estimators 11973
by Roman Yurchak
•FIXFixed a bug in the implementation of the ourrandr helper function that was not behaving consistently
across platforms 13422 by Madhura Parikh and Clément Doumouro
Miscellaneous
•ENHANCEMENT Joblib is no longer vendored in scikitlearn and becomes a dependency Minimal supported
version is joblib 011 however using version 013 is strongly recommended 13531 by Roman Yurchak
1114 Changes to estimator checks
These changes mostly affect library developers
• Addcheckfitidempotent tocheckestimator which checks that when fitis called twice with the
same data the ouput of predict predictproba transform and decisionfunction does not change 12328 by
Nicolas Hug
• Many checks can now be disabled or configured with Estimator Tags 8022 by Andreas Müller
1115 Code and Documentation Contributors

112 Version 0204
July 30 2019
This is a bugfix release with some bug fixes applied to version 0203
1121 Changelog
The bundled version of joblib was upgraded from 0130 to 0132
sklearncluster
•FIXFixed a bug in clusterKMeans where KMeans initialisation could rarely result in an IndexError 11756 by Joel Nothman
sklearncompose
•FIXFixed an issue in composeColumnTransformer where using DataFrames whose column order differs between func fit and functransform could lead to silently passing incorrect columns to the remainder transformer 14237 by Andreas Schuderer
sklearnmodelselection
•FIXFixed a bug where modelselectionStratifiedKFold shuffles each class's samples with the samerandomstate makingshuffleTrue ineffective 13124 by Hanmin Qin

sklearnneighbors
•FIXFixed a bug in neighborsKernelDensity which could not be restored from a pickle if sampleweight had been used 13772 by Aditya Vyas

113 Version 0203

March 1 2019

This is a bugfix release with some minor documentation improvements and enhancements to features released in 0200

1131 Changelog

sklearncluster
•FIXFixed a bug in clusterKMeans where computation was single threaded when njobs 1 or njobs 1 12949 by Prabakaran Kumaresshan

sklearncompose
•FIXFixed a bug in composeColumnTransformer to handle negative indexes in the columns list of the transformers 12946 by Pierre Tallotte

sklearncovariance
•FIXFixed a regression in covariancegraphicallasso so that the case nfeatures2 is handled correctly 13276 by Aurélien Bellet

sklearndecomposition
•FIXFixed a bug in decompositionsparseencode where computation was single threaded when njobs 1 ornjobs 1 13005 by Prabakaran Kumaresshan

sklearndatasets
•EFFICIENCY sklearndatasetsfetchopenml now loads data by streaming avoiding high memory usage 13312 by Joris Van den Bossche

sklearnfeatureextraction
•FIXFixed a bug in featureextractiontextCountVectorizer which would result in the sparse feature matrix having conflicting indptr andindices precisions under very large vocabularies 11295 by Gabriel Vacaliuc

scikitlearn user guide Release 0213
sklearnimpute
•FIXadd support for nonnumeric data in sklearnimputeMissingIndicator which was not sup
ported while sklearnimputeSimpleImputer was supporting this for some imputation strategies
13046 by Guillaume Lemaitre
sklearnlinearmodel
•FIXFixed a bug in linearmodelMultiTaskElasticNet andlinearmodel
MultiTaskLasso which were breaking when warmstart True 12360 by Aakanksha Joshi
sklearnpreprocessing
•FIXFixed a bug in preprocessingKBinsDiscretizer wherestrategykmeans fails with an
error during transformation due to unsorted bin edges 13134 by Sandro Casagrande
•FIXFixed a bug in preprocessingOneHotEncoder where the deprecation of
categoricalfeatures was handled incorrectly in combination with handleunknownignore
12881 by Joris Van den Bossche
•FIXBins whose width are too small ie 1e8 are removed with a warning in preprocessing
KBinsDiscretizer 13165 by Hanmin Qin
sklearnsvm
•FIXFixed a bug in svmSVC svmNuSVC svmSVR svmNuSVR andsvmOneClassSVM where the
scale option of parameter gamma is erroneously defined as 1 nfeatures Xstd It's now
defined as1 nfeatures Xvar 13221 by Hanmin Qin

114 Version 0202
December 20 2018
This is a bugfix release with some minor documentation improvements and enhancements to features released in
0200

1141 Changed models
The following estimators and functions when fit with the same data and parameters may produce different models from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in random sampling procedures
•sklearnneighbors whenmetricjaccard bug fix
• use ofseuclidean ormahalanobis metrics in some cases bug fix
1142 Changelog
sklearncompose
•FIXFixed an issue in composemakecolumntransformer which raises unexpected error when columns is pandas Index or pandas Series 12704 by Hanmin Qin
sklearnmetrics
•FIX Fixed a bug in metricspairwisedistances andmetrics pairwisedistanceschunked where parameters Vofseuclidean andVIofmahalanobis metrics were computed after the data was split into chunks instead of being precomputed on whole data 12701 by Jeremie du Boisberranger
sklearnneighbors
•FIXFixedsklearnneighborsDistanceMetric jaccard distance function to return 0 when two all zero vectors are compared 12685 by Thomas Fan
sklearnutils
•FIXCallingutilscheckarray onpandasSeries with categorical data which raised an error in 0200 now returns the expected output again 12699 by Joris Van den Bossche
1143 Code and Documentation Contributors
With thanks to
adanhawth Adrin Jalali Albert Thomas Andreas Mueller Dan Stine Feda Curic Hanmin Qin Jan S jeremiedbb Joel Nothman Joris Van den Bossche josephsalmon Katrin Leinweber Loic Esteve Muhammad Hassaan Rafique Nicolas Hug Olivier Grisel Paul Paczuski Reshama Shaikh Sam Waterbury Shivam Kotwalia Thomas Fan
115 Version 0201
November 21 2018
This is a bugfix release with some minor documentation improvements and enhancements to features released in 0200 Note that we also include some API changes in this release so you might get some extra warnings after updating from 0200 to 0201

1151 Changed models

The following estimators and functions when fit with the same data and parameters may produce different models from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in random sampling procedures

- decompositionIncrementalPCA bug fix

1152 Changelog

sklearncluster

- EFFICIENCY makeclusterMeanShift no longer try to do nested parallelism as the overhead would hurt performance significantly when njobs 1 12159 by Olivier Grisel
- FIXFixed a bug in clusterDBSCAN with precomputed sparse neighbors graph which would add explicitly zeros on the diagonal even when already present 12105 by Tom Dupre la Tour

sklearncompose

- FIXFixed an issue in composeColumnTransformer when stacking columns with types not convertible to a numeric 11912 by Adrin Jalali
- API C HANGE composeColumnTransformer now applies the sparsethreshold even if all trans formation results are sparse 12304 by Andreas Müller
- API C HANGE composemakecolumntransformer now expects transformer columns in stead ofcolumns transformer to keep consistent with composeColumnTransformer 12339 by Adrin Jalali

sklearndatasets

- FIXdatasetsfetchopenml to correctly use the local cache 12246 by Jan N van Rijn
- FIXdatasetsfetchopenml to correctly handle ignore attributes and row id attributes 12330 by Jan N van Rijn
- FIXFixed integer overflow in datasetsmakeclassification for values of ninformative pa rameter larger than 64 10811 by Roman Feldbauer
- FIXFixed olivetti faces dataset DESCR attribute to point to the right location in datasets fetcholivettifaces 12441 by Jérémie du Boisberranger
- FIXdatasetsfetchopenml to retry downloading when reading from local cache fails 12517 by Thomas Fan

sklearndecomposition

- FIXFixed a regression in decompositionIncrementalPCA where 0200 raised an error if the number of samples in the final batch for fitting IncrementalPCA was smaller than ncomponents 12234 by Ming Li

sklearnensemble
•FIX Fixed a bug mostly affecting ensembleRandomForestClassifier where
classweightbalancedsubsample failed with more than 32 classes 12165 by Joel Nothman
•FIXFixed a bug affecting ensembleBaggingClassifier ensembleBaggingRegressor and
ensembleIsolationForest wheremaxfeatures was sometimes rounded down to zero 12388
by Connor Tann
sklearnfeatureextraction
•FIXFixed a regression in v0200 where featureextractiontextCountVectorizer and other
text vectorizers could error during stop words validation with custom preprocessors or tokenizers 12393 by
Roman Yurchak
sklearnlinearmodel
•FIXlinearmodelSGDClassifier and variants with earlystoppingTrue would not use a
consistent validation split in the multiclass case and this would cause a crash when using those estimators as
part of parallel parameter search or crossvalidation 12122 by Olivier Grisel
•FIXFixed a bug affecting SGDClassifier in the multiclass case Each oneversusall step is run in a
joblibParallel call and mutating a common parameter causing a segmentation fault if called within a
backend using processes and not threads We now use requiresharedmem at thejoblibParallel
instance creation 12518 by Pierre Glaser and Olivier Grisel
sklearnmetrics
•FIXFixed a bug in metricspairwisepairwisedistancesargminmin which returned the
square root of the distance when the metric parameter was set to “euclidean” 12481 by Jérémie du Boisber
ranger
•FIXFixed a bug in metricspairwisepairwisedistanceschunked which didn’t ensure the
diagonal is zero for euclidean distances 12612 by Andreas Müller
•API C HANGE Themetricscalinskiharabazscore has been renamed to metrics
calinskiharabaszscore and will be removed in version 023 12211 by Lisa Thomas Mark Hannel
and Melissa Ferrari
sklearnmixture
•FIXEnsure that the fitpredict method of mixtureGaussianMixture andmixture
BayesianGaussianMixture always yield assignments consistent with fit followed by predict even
if the convergence criterion is too loose or not met 12451 by Olivier Grisel
sklearnneighbors
•FIXforce the parallelism backend to threading forneighborsKDTree andneighborsBallTree
in Python 27 to avoid pickling errors caused by the serialization of their methods 12171 by Thomas Moreau

scikitlearn user guide Release 0213
sklearnpreprocessing
•FIXFixed bug in preprocessingOrdinalEncoder when passing manually specified categories 12365 by Joris Van den Bossche
•FIXFixed bug in preprocessingKBinsDiscretizer where thetransform method mutates the encoder attribute The transform method is now thread safe 12514 by Hanmin Qin
•FIXFixed a bug in preprocessingPowerTransformer where the YeoJohnson transform was incorrect for lambda parameters outside of 0 2 12522 by Nicolas Hug
•FIXFixed a bug in preprocessingOneHotEncoder where transform failed when set to ignore unknown numpy strings of different lengths 12471 by Gabriel Marzinotto
•API C HANGE The default value of the method argument in preprocessingpowertransform will be changed from boxcox toyeojohnson to matchpreprocessingPowerTransformer in version 023 A FutureWarning is raised when the default value is used 12317 by Eric Chang
sklearnutils
•FIXUse float64 for mean accumulator to avoid floating point precision issues in preprocessing StandardScaler anddecompositionIncrementalPCA when using float32 datasets 12338 by bauks
•FIXCallingutilscheckarray onpandasSeries which raised an error in 0200 now returns the expected output again 12625 by Andreas Müller
Miscellaneous
•FIXWhen using site joblib by setting the environment variable SKLEARNSITEJOBLIB added compatibility with joblib 011 in addition to 012 12350 by Joel Nothman and Roman Yurchak
•FIXMake sure to avoid raising FutureWarning when calling npvstack with numpy 116 and later use list comprehensions instead of generator expressions in many locations of the scikitlearn code base 12467 by Olivier Grisel
•API C HANGE Removed all mentions of sklearnexternalsjoblib and deprecated joblib methods exposed in sklearnutils except for utilsparallelbackend andutils registerparallelbackend which allow users to configure parallel computation in scikitlearn Other functionalities are part of joblib package and should be used directly by installing it The goal of this change is to prepare for unvendoring joblib in future version of scikitlearn 12345 by Thomas Moreau

116 Version 0200

September 25 2018

This release packs in a mountain of bug fixes features and enhancements for the Scikitlearn library and improvements to the documentation and examples Thanks to our contributors

This release is dedicated to the memory of Raghav Rajagopalan

Warning Version 020 is the last version of scikitlearn to support Python 27 and Python 34 Scikitlearn 021 will require Python 35 or higher

1161 Highlights

We have tried to improve our support for common datascience usecases including missing values categorical variables heterogeneous data and featurestargets with unusual distributions Missing values in features represented by NaNs are now accepted in columnwise preprocessing such as scalers Each feature is fitted disregarding NaNs and data containing NaNs can be transformed The new impute module provides estimators for learning despite missing data

ColumnTransformer handles the case where different features or columns of a pandasDataFrame need different preprocessing String or pandas Categorical columns can now be encoded with OneHotEncoder or OrdinalEncoder

TransformedTargetRegressor helps when the regression target needs to be transformed to be modeled PowerTransformer andKBinsDiscretizer joinQuantileTransformer as nonlinear transformations

Beyond this we have added sampleweight support to several estimators including KMeans BayesianRidge andKernelDensity and improved stopping criteria in others including MLPRegressor GradientBoostingRegressor andSGDRegressor

This release is also the first to be accompanied by a Glossary of Common Terms and API Elements developed by Joel Nothman The glossary is a reference resource to help users and contributors become familiar with the terminology and conventions used in Scikitlearn

Sorry if your contribution didn’t make it into the highlights There’s a lot here

1162 Changed models

The following estimators and functions when fit with the same data and parameters may produce different models from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in random sampling procedures

- clusterMeanShift bug fix
- decompositionIncrementalPCA in Python 2 bug fix
- decompositionSparsePCA bug fix
- ensembleGradientBoostingClassifier bug fix affecting feature importances
- isotonicIsotonicRegression bug fix
- linearmodelARDRegression bug fix
- linearmodelLogisticRegressionCV bug fix
- linearmodelOrthogonalMatchingPursuit bug fix

•linearmodelPassiveAggressiveClassifier bug fix
•linearmodelPassiveAggressiveRegressor bug fix
•linearmodelPerceptron bug fix
•linearmodelSGDClassifier bug fix
•linearmodelSGDRegressor bug fix
•metricsrocaucscore bug fix
•metricsroccurve bug fix
•neuralnetworkBaseMultilayerPerceptron bug fix
•neuralnetworkMLPClassifier bug fix
•neuralnetworkMLPRegressor bug fix
• The v0190 release notes failed to mention a backwards incompatibility with modelselection StratifiedKFold whenshuffleTrue due to 7823
Details are listed in the changelog below
While we are trying to better inform users by providing this information we cannot assure that this list is complete
1163 Known Major Bugs
• 11924 linearmodelLogisticRegressionCV withsolverlbfgs and multiclassmultinomial may be nondeterministic or otherwise broken on macOS This appears to be the case on Travis CI servers but has not been confirmed on personal MacBooks This issue has been present in previous releases
• 9354metricspairwiseeuclideandistances which is used several times throughout the library gives results with poor precision which particularly affects its use with 32bit float inputs This became more problematic in versions 018 and 019 when some algorithms were changed to avoid casting 32bit data into 64bit
1164 Changelog
Support for Python 33 has been officially dropped
sklearncluster
•MAJOR FEATURE clusterAgglomerativeClustering now supports Single Linkage clustering via linkagesingle 9372 by Leland McInnes and Steve Astels
•FEATURE clusterKMeans andclusterMiniBatchKMeans now support sample weights via new parametersampleweight infit function 10933 by Johannes Hansen
•EFFICIENCY clusterKMeans clusterMiniBatchKMeans andclusterkmeans passed with algorithmfull now enforces rowmajor ordering improving runtime 10471 by Gaurav Dhingra
•EFFICIENCY clusterDBSCAN now is parallelized according to njobs regardless of algorithm 8003 by Joël Billaud
•ENHANCEMENT clusterKMeans now gives a warning if the number of distinct clusters found is smaller thannclusters This may occur when the number of distinct points in the data set is actually smaller than the number of cluster one is looking for 10059 by Christian Braune

•FIXFixed a bug where the fit method ofclusterAffinityPropagation stored cluster centers as 3d array instead of 2d array in case of nonconvergence For the same class fixed undefined and arbitrary behavior in case of training data where all samples had equal similarity 9612 By Jonatan Samoocha
•FIXFixed a bug in clusterspectralclustering where the normalization of the spectrum was using a division instead of a multiplication 8129 by Jan Margeta Guillaume Lemaitre and Devansh D
•FIXFixed a bug in clusterkmeanselkan where the returned iteration was 1 less than the correct value Also added the missing niter attribute in the docstring of clusterKMeans 11353 by Jeremie du Boisberranger
•FIXFixed a bug in clustermeanshift where the assigned labels were not deterministic if there were multiple clusters with the same intensities 11901 by Adrin Jalali
•API C HANGE Deprecate poolingfunc unused parameter in cluster AgglomerativeClustering 9875 by Kumar Ashutosh

sklearncompose

• New module
•MAJOR FEATURE AddedcomposeColumnTransformer which allows to apply different transformers to different columns of arrays or pandas DataFrames 9012 by Andreas Müller and Joris Van den Bossche and 11315 by Thomas Fan
•MAJOR FEATURE Added thecomposeTransformedTargetRegressor which transforms the target y before fitting a regression model The predictions are mapped back to the original space via an inverse transform 9041 by Andreas Müller and Guillaume Lemaitre

sklearncovariance

•EFFICIENCY Runtime improvements to covarianceGraphicalLasso 9858 by Steven Brown
•API C HANGE Thecovariancegraphlasso covarianceGraphLasso andcovariance GraphLassoCV have been renamed to covariancegraphicallasso covariance GraphicalLasso andcovarianceGraphicalLassoCV respectively and will be removed in version 022 9993 by Artiem Krinitsyn

sklearndatasets

•MAJOR FEATURE Addeddatasetsfetchopenml to fetch datasets from OpenML OpenML is a free open data sharing platform and will be used instead of mldata as it provides better service availability 9908 by Andreas Müller and Jan N van Rijn
•FEATURE Indatasetsmakeblobs one can now pass a list to the nsamples parameter to indicate the number of samples to generate per cluster 8617 by Maskani Filali Mohamed and Konstantinos Katrioplas
•FEATURE Addfilename attribute to datasets that have a CSV file 9101 by alex33 and Maskani Filali Mohamed
•FEATURE returnXy parameter has been added to several dataset loaders 10774 by Chris Catalfo
•FIXFixed a bug in datasetsloadboston which had a wrong data point 10795 by Takeshi Yoshizawa
•FIXFixed a bug in datasetsloadiris which had two wrong data points 11082 by Sadhana Srini vasan and Hanmin Qin

•FIXFixed a bug in datasetsfetchkddcup99 where data were not properly shuffled 9731 by Nico las Goix
•FIXFixed a bug in datasetsmakecircles where no odd number of data points could be generated 10045 by Christian Braune
•API C HANGE Deprecated sklearndatasetsfetchmldata to be removed in version 022 ml dataorg is no longer operational Until removal it will remain possible to load cached datasets 11466 by Joel Nothman

sklearndecomposition

•FEATURE decompositiondictlearning functions and models now support positivity constraints This applies to the dictionary and sparse code 6374 by John Kirkham
•FEATURE F IXdecompositionSparsePCA now exposes normalizecomponents When set to True the train and test data are centered with the train mean repsectively during the fit phase and the transform phase This fixes the behavior of SparsePCA When set to False which is the default the previous abnormal behaviour still holds The False value is for backward compatibility and should not be used 11585 by Ivan Panico
•EFFICIENCY Efficiency improvements in decompositiondictlearning 11420 and others by John Kirkham
•FIXFix for uninformative error in decompositionIncrementalPCA now an error is raised if the number of components is larger than the chosen batch size The ncomponentsNone case was adapted accordingly 6452 By Wally Gauze
•FIXFixed a bug where the partialfit method ofdecompositionIncrementalPCA used integer division instead of float division on Python 2 9492 by James Bourbeau
•FIXIndecompositionPCA selecting a ncomponents parameter greater than the number of samples now raises an error Similarly the ncomponentsNone case now selects the minimum of nsamples and nfeatures 8484 by Wally Gauze
•FIXFixed a bug in decompositionPCA where users will get unexpected error with large datasets when ncomponentsmle on Python 3 versions 9886 by Hanmin Qin
•FIXFixed an underflow in calculating KLdivergence for decompositionNMF 10142 by Tom Dupre la Tour
•FIXFixed a bug in decompositionSparseCoder when running OMP sparse coding in parallel using readonly memory mapped datastructures 5956 by Vighnesh Birodkar and Olivier Grisel

sklearndiscriminantanalysis

•EFFICIENCY Memory usage improvement for classmeans andclasscov in discriminantanalysis 10898 by Nanxin Chen

sklearndummy

•FEATURE dummyDummyRegressor now has areturnstd option in its predict method The re turned standard deviations will be zeros
•FEATURE dummyDummyClassifier anddummyDummyRegressor now only require X to be an ob ject with finite length or shape 9832 by Vrishank Bhardwaj

•FEATURE dummyDummyClassifier anddummyDummyRegressor can now be scored without sup
plying test samples 11951 by Rüdiger Busche
sklearnensemble
•FEATURE ensembleBaggingRegressor andensembleBaggingClassifier can now be fit
with missingnonfinite values in X andor multioutput Y to support wrapping pipelines that perform their
own imputation 9707 by Jimmy Wan
•FEATURE ensembleGradientBoostingClassifier and ensemble
GradientBoostingRegressor now support early stopping via niternochange
validationfraction andtol 7071 by Raghav RV
•FEATURE Addednamedestimators parameter in ensembleVotingClassifier to access fitted
estimators 9157 by Herilalaina Rakotoarison
•FIXFixed a bug when fitting ensembleGradientBoostingClassifier orensemble
GradientBoostingRegressor withwarmstartTrue which previously raised a segmentation fault
due to a nonconversion of CSC matrix into CSR format expected by decisionfunction Similarly
Fortranordered arrays are converted to Cordered arrays in the dense case 9991 by Guillaume Lemaitre
•FIXFixed a bug in ensembleGradientBoostingRegressor andensemble
GradientBoostingClassifier to have feature importances summed and then normalized rather
than normalizing on a pertree basis The previous behavior overweighted the Gini importance of features that
appear in later stages This issue only affected feature importances 11176 by Gil Forsyth
•API C HANGE The default value of the nestimators parameter of ensemble
RandomForestClassifier ensembleRandomForestRegressor ensemble
ExtraTreesClassifier ensembleExtraTreesRegressor and ensemble
RandomTreesEmbedding will change from 10 in version 020 to 100 in 022 A FutureWarning is
raised when the default value is used 11542 by Anna Ayzenshtat
•API C HANGE Classes derived from ensembleBaseBagging The attribute estimatorssamples
will return a list of arrays containing the indices selected for each bootstrap instead of a list of arrays containing
the mask of the samples selected for each bootstrap Indices allows to repeat samples while mask does not allow
this functionality 9524 by Guillaume Lemaitre
•FIXensembleBaseBagging where one could not deterministically reproduce fit result using the object
attributes when randomstate is set 9723 by Guillaume Lemaitre
sklearnfeatureextraction
•FEATURE Enable the call to getfeaturenames in unfitted featureextractiontext
CountVectorizer initialized with a vocabulary 10908 by Mohamed Maskani
•ENHANCEMENT idf can now be set on a featureextractiontextTfidfTransformer
10899 by Sergey Melderis
•FIXFixed a bug in featureextractionimageextractpatches2d which would throw an
exception if maxpatches was greater than or equal to the number of all possible patches rather than simply
returning the number of possible patches 10101 by Varun Agrawal
•FIXFixed a bug in featureextractiontextCountVectorizer featureextraction
textTfidfVectorizer featureextractiontextHashingVectorizer to support 64 bit
sparse array indexing necessary to process large datasets with more than 2·109tokens words or ngrams
9147 by ClaesFredrik Mannby and Roman Yurchak

•FIXFixed bug in featureextractiontextTfidfVectorizer which was ignoring the parame
terdtype In addition featureextractiontextTfidfTransformer will preserve dtype for
floating and raise a warning if dtype requested is integer 10441 by Mayur Kulkarni and Guillaume Lemaitre
sklearnfeatureselection
•FEATURE Added select K best features functionality to featureselectionSelectFromModel
6689 by Nihar Sheth and Quazi Rahman
•FEATURE Addedminfeaturestoselect parameter to featureselectionRFECV to bound
evaluated features counts 11293 by Brent Yi
•FEATURE featureselectionRFECV ’s fit method now supports groups 9656 by Adam Greenhall
•FIXFixed computation of nfeaturestocompute for edge case with tied CV scores in
featureselectionRFECV 9222 by Nick Hoh
sklearngaussianprocess
•EFFICIENCY IngaussianprocessGaussianProcessRegressor methodpredict is faster
when using returnstdTrue in particular more when called several times in a row 9234 by andrewww
and Minghui Liu
sklearnimpute
• New module adopting preprocessingImputer asimputeSimpleImputer with minor changes
see under preprocessing below
•MAJOR FEATURE AddedimputeMissingIndicator which generates a binary indicator for missing
values 8075 by Maniteja Nandana and Guillaume Lemaitre
•FEATURE TheimputeSimpleImputer has a new strategy constant to complete missing values
with a fixed one given by the fillvalue parameter This strategy supports numeric and nonnumeric data
and so does the mostfrequent strategy now 11211 by Jeremie du Boisberranger
sklearnisotonic
•FIXFixed a bug in isotonicIsotonicRegression which incorrectly combined weights when fitting
a model to data involving points with identical X values 9484 by Dallas Card
sklearnlinearmodel
•FEATURE linearmodelSGDClassifier linearmodelSGDRegressor linearmodel
PassiveAggressiveClassifier linearmodelPassiveAggressiveRegressor and
linearmodelPerceptron now expose earlystopping validationfraction and
niternochange parameters to stop optimization monitoring the score on a validation set A new learn
ing rateadaptive strategy divides the learning rate by 5 each time niternochange consecutive
epochs fail to improve the model 9043 by Tom Dupre la Tour
•FEATURE Add sampleweight parameter to the fit method of linearmodelBayesianRidge for
weighted linear regression 10112 by Peter St John

•FIXFixed a bug in logisticlogisticregressionpath to ensure that the returned coefficients
are correct when multiclassmultinomial Previously some of the coefficients would override each
other leading to incorrect results in linearmodelLogisticRegressionCV 11724 by Nicolas Hug
•FIXFixed a bug in linearmodelLogisticRegression where when using the parameter
multiclassmultinomial thepredictproba method was returning incorrect probabilities in
the case of binary outcomes 9939 by Roger Westover
•FIXFixed a bug in linearmodelLogisticRegressionCV where thescore method always com
putes accuracy not the metric given by the scoring parameter 10998 by Thomas Fan
•FIXFixed a bug in linearmodelLogisticRegressionCV where the ‘ovr’ strategy was always used
to compute crossvalidation scores in the multiclass setting even if multinomial was set 8720 by
William de Vazelhes
•FIXFixed a bug in linearmodelOrthogonalMatchingPursuit that was broken when setting
normalizeFalse 10071 by Alexandre Gramfort
•FIXFixed a bug in linearmodelARDRegression which caused incorrectly updated estimates for the
standard deviation and the coefficients 10153 by Jörg Döpfert
•FIXFixed a bug in linearmodelARDRegression andlinearmodelBayesianRidge which
caused NaN predictions when fitted with a constant target 10095 by Jörg Döpfert
•FIXFixed a bug in linearmodelRidgeClassifierCV where the parameter storecvvalues
was not implemented though it was documented in cvvalues as a way to set up the storage of cross
validation values for different alphas 10297 by Mabel VillalbaJiménez
•FIXFixed a bug in linearmodelElasticNet which caused the input to be overridden when using
parametercopyXTrue andcheckinputFalse 10581 by Yacine Mazari
•FIXFixed a bug in sklearnlinearmodelLasso where the coefficient had wrong shape when
fitinterceptFalse 10687 by Martin Hahn
•FIXFixed a bug in sklearnlinearmodelLogisticRegression where the
multiclassmultinomial with binary output with warmstartTrue 10836 by Aish
warya Srinivasan
•FIXFixed a bug in linearmodelRidgeCV where using integer alphas raised an error 10397 by
Mabel VillalbaJiménez
•FIXFixed condition triggering gap computation in linearmodelLasso andlinearmodel
ElasticNet when working with sparse matrices 10992 by Alexandre Gramfort
•FIX Fixed a bug in linearmodelSGDClassifier linearmodel
SGDRegressor linearmodelPassiveAggressiveClassifier linearmodel
PassiveAggressiveRegressor andlinearmodelPerceptron where the stopping criterion
was stopping the algorithm before convergence A parameter niternochange was added and set by
default to 5 Previous behavior is equivalent to setting the parameter to 1 9043 by Tom Dupre la Tour
•FIXFixed a bug where liblinear and libsvmbased estimators would segfault if passed a scipysparse matrix
with 64bit indices They now raise a ValueError 11327 by Karan Dhingra and Joel Nothman
•API C HANGE The default values of the solver andmulticlass parameters of linearmodel
LogisticRegression will change respectively from liblinear andovr in version 020 to
lbfgs andauto in version 022 A FutureWarning is raised when the default values are used 11905
by Tom Dupre la Tour and Joel Nothman
•API C HANGE DeprecatepositiveTrue option inlinearmodelLars as the underlying implemen
tation is broken Use linearmodelLasso instead 9837 by Alexandre Gramfort

scikitlearn user guide Release 0213
•API C HANGE niter may vary from previous releases in linearmodelLogisticRegression withsolverlbfgs andlinearmodelHuberRegressor For Scipy 100 the optimizer could perform more than the requested maximum number of iterations Now both estimators will report at most maxiter iterations even if more were performed 10723 by Joel Nothman

sklearnmanifold

•EFFICIENCY Speed improvements for both 'exact' and 'barneshut' methods in manifoldTSNE 10593 and 10610 by Tom Dupre la Tour
•FEATURE Support sparse input in manifoldIsomapfit 8554 by Leland McInnes
•FEATURE manifoldtsnetrustworthiness accepts metrics other than Euclidean 9775 by William de Vazelhes
•FIXFixed a bug in manifoldspectralembedding where the normalization of the spectrum was using a division instead of a multiplication 8129 by Jan Margeta Guillaume Lemaitre and Devansh D
•API C HANGE F EATURE Deprecate precomputed parameter in function manifoldtsne trustworthiness Instead the new parameter metric should be used with any compatible metric in cluding 'precomputed' in which case the input matrix Xshould be a matrix of pairwise distances or squared distances 9775 by William de Vazelhes
•API C HANGE Deprecateprecomputed parameter in function manifoldtsnetrustworthiness Instead the new parameter metric should be used with any compatible metric including 'precomputed' in which case the input matrix Xshould be a matrix of pairwise distances or squared distances 9775 by William de Vazelhes

sklearnmetrics

•MAJOR FEATURE Added themetricsdaviesbouldinscore metric for evaluation of clustering mod els without a ground truth 10827 by Luis Osa
•MAJOR FEATURE Added the metricsbalancedaccuracyscore metric and a corresponding balancedaccuracy scorer for binary and multiclass classification 8066 by xyguo and Aman Dalmia and 10587 by Joel Nothman
•FEATURE Partial AUC is available via maxfpr parameter in metricsrocaucscore 3840 by Alexander Niederbühl
•FEATURE A scorer based on metricsbrierscoreloss is also available 9521 by Hanmin Qin
•FEATURE Added control over the normalization in metricsnormalizedmutualinfoscore and metricsadjustedmutualinfoscore via theaveragemethod parameter In version 022 the default normalizer for each will become the arithmetic mean of the entropies of each clustering 11124 by Arya McCarthy
•FEATURE Addedoutputdict parameter in metricsclassificationreport to return classifi cation statistics as dictionary 11160 by Dan Barkhorn
•FEATURE metricsclassificationreport now reports all applicable averages on the given data in cluding micro macro and weighted average as well as samples average for multilabel data 11679 by Alexander Pacha
•FEATURE metricsaverageprecisionscore now supports binary ytrue other than0 1 or 1 1 throughposlabel parameter 9980 by Hanmin Qin
•FEATURE metricslabelrankingaverageprecisionscore now supports sampleweight 10845 by Jose PerezParras Toledano

•FEATURE Adddenseoutput parameter to metricspairwiselinearkernel When False and
both inputs are sparse will return a sparse matrix 10999 by Taylor G Smith
•EFFICIENCY metricssilhouettescore andmetricssilhouettesamples are more mem
ory efficient and run faster This avoids some reported freezes and MemoryErrors 11135 by Joel Nothman
•FIXFixed a bug in metricsprecisionrecallfscoresupport when truncated
rangenlabels is passed as value for labels 10377 by Gaurav Dhingra
•FIXFixed a bug due to floating point error in metricsrocaucscore with noninteger sample weights
9786 by Hanmin Qin
•FIXFixed a bug where metricsroccurve sometimes starts on yaxis instead of 0 0 which is in
consistent with the document and other implementations Note that this will not influence the result from
metricsrocaucscore 10093 by alexryndin and Hanmin Qin
•FIXFixed a bug to avoid integer overflow Casted product to 64 bits integer in metrics
mutualinfoscore 9772 by Kumar Ashutosh
•FIXFixed a bug where metricsaverageprecisionscore will sometimes return nan when
sampleweight contains 0 9980 by Hanmin Qin
•FIXFixed a bug in metricsfowlkesmallowsscore to avoid integer overflow Casted return value
ofContingency Matrix toint64 and computed product of square roots rather than square root of product
9515 by Alan Liddell and Manh Dao
•API C HANGE Deprecatereorder parameter in metricsauc as it’s no longer required for metrics
rocaucscore Moreover using reorderTrue can hide bugs due to floating point error in the input
9851 by Hanmin Qin
•API C HANGE Inmetricsnormalizedmutualinfoscore andmetrics
adjustedmutualinfoscore warn that averagemethod will have a new default value
In version 022 the default normalizer for each will become the arithmetic mean of the entropies of
each clustering Currently metricsnormalizedmutualinfoscore uses the default of
averagemethodgeometric andmetricsadjustedmutualinfoscore uses the
default ofaveragemethodmax to match their behaviors in version 019 11124 by Arya McCarthy
•API C HANGE Thebatchsize parameter to metricspairwisedistancesargminmin and
metricspairwisedistancesargmin is deprecated to be removed in v022 It no longer has any ef
fect as batch size is determined by global workingmemory config See Limiting Working Memory 10280
by Joel Nothman and Aman Dalmia
sklearnmixture
•FEATURE Added function fitpredict tomixtureGaussianMixture andmixture
GaussianMixture which is essentially equivalent to calling fitand predict 10336 by Shu Haoran
and Andrew Peng
•FIXFixed a bug in mixtureBaseMixture where the reported niter was missing an iteration It af
fectedmixtureGaussianMixture andmixtureBayesianGaussianMixture 10740 by Erich
Schubert and Guillaume Lemaitre
•FIXFixed a bug in mixtureBaseMixture and its subclasses mixtureGaussianMixture and
mixtureBayesianGaussianMixture where thelowerbound was not the max lower bound across
all initializations when ninit 1 but just the lower bound of the last initialization 10869 by Aurélien
Géron

sklearnmodelselection
•FEATURE Addreturnestimator parameter in modelselectioncrossvalidate to return es
timators fitted on each split 9686 by Aurélien Bellet
•FEATURE Newrefittime attribute will be stored in modelselectionGridSearchCV and
modelselectionRandomizedSearchCV ifrefit is set toTrue This will allow measuring the
complete time it takes to perform hyperparameter optimization and refitting the best model on the whole dataset
11310 by Matthias Feurer
•FEATURE Exposeerrorscore parameter in modelselectioncrossvalidate
modelselectioncrossvalscore modelselectionlearningcurve and
modelselectionvalidationcurve to control the behavior triggered when an error occurs in
modelselectionfitandscore 11576 by Samuel O Ronsin
•FEATURE BaseSearchCV now has an experimental private interface to support customized parameter
search strategies through its runsearch method See the implementations in modelselection
GridSearchCV andmodelselectionRandomizedSearchCV and please provide feedback if you
use this Note that we do not assure the stability of this API beyond version 020 9599 by Joel Nothman
•ENHANCEMENT Add improved error message in modelselectioncrossvalscore when multiple
metrics are passed in scoring keyword 11006 by Ming Li
•API C HANGE The default number of crossvalidation folds cvand the default number of splits nsplits in
themodelselectionKFold like splitters will change from 3 to 5 in 022 as 3fold has a lot of variance
11557 by Alexandre Boucaud
•API C HANGE The default of iid parameter of modelselectionGridSearchCV and
modelselectionRandomizedSearchCV will change from True toFalse in version 022 to
correspond to the standard definition of crossvalidation and the parameter will be removed in version
024 altogether This parameter is of greatest practical significance where the sizes of different test sets in
crossvalidation were very unequal ie in groupbased CV strategies 9085 by Laurent Direr and Andreas
Müller
•API C HANGE The default value of the errorscore parameter in modelselectionGridSearchCV
andmodelselectionRandomizedSearchCV will change to npNaN in version 022 10677 by
Kirill Zhdanovich
•API C HANGE Changed ValueError exception raised in modelselectionParameterSampler to a
UserWarning for case where the class is instantiated with a greater value of niter than the total space of
parameters in the parameter grid niter now acts as an upper bound on iterations 10982 by Juliet Lawton
•API C HANGE Invalid input for modelselectionParameterGrid now raises TypeError 10928 by
Solutus Immensus
sklearnmultioutput
•MAJOR FEATURE AddedmultioutputRegressorChain for multitarget regression 9257 by Kumar
Ashutosh
sklearnnaivebayes
•MAJOR FEATURE AddednaivebayesComplementNB which implements the Complement Naive Bayes
classifier described in Rennie et al 2003 8190 by Michael A Alcorn
•FEATURE Addvarsmoothing parameter in naivebayesGaussianNB to give a precise control over
variances calculation 9681 by Dmitry Mottl

•FIXFixed a bug in naivebayesGaussianNB which incorrectly raised error for prior list which summed
to 1 10005 by Gaurav Dhingra
•FIXFixed a bug in naivebayesMultinomialNB which did not accept vector valued pseudocounts
alpha 10346 by Tobias Madsen
sklearnneighbors
•EFFICIENCY neighborsRadiusNeighborsRegressor and neighbors
RadiusNeighborsClassifier are now parallelized according to njobs regardless of algorithm
10887 by Joël Billaud
•EFFICIENCY Nearest neighbors query methods are now more memory efficient when
algorithmbrute 11136 by Joel Nothman and Aman Dalmia
•FEATURE Addsampleweight parameter to the fit method of neighborsKernelDensity to enable
weighting in kernel density estimation 4394 by Samuel O Ronsin
•FEATURE Novelty detection with neighborsLocalOutlierFactor Add a novelty param
eter toneighborsLocalOutlierFactor When novelty is set to True neighbors
LocalOutlierFactor can then be used for novelty detection ie predict on new unseen data Available
prediction methods are predict decisionfunction andscoresamples By default novelty is
set toFalse and only the fitpredict method is avaiable By Albert Thomas
•FIXFixed a bug in neighborsNearestNeighbors where fitting a NearestNeighbors model fails when
a the distance metric used is a callable and b the input to the NearestNeighbors model is sparse 9579 by
Thomas Kober
•FIXFixed a bug so predict inneighborsRadiusNeighborsRegressor can handle empty neigh
bor set when using non uniform weights Also raises a new warning when no neighbors are found for samples
9655 by Andreas BjerreNielsen
•FIX E FFICIENCY Fixed a bug in KDTree construction that results in faster construction and querying times
11556 by Jake VanderPlas
•FIXFixed a bug in neighborsKDTree andneighborsBallTree where pickled tree objects would
change their type to the super class BinaryTree 11774 by Nicolas Hug
sklearnneuralnetwork
•FEATURE Add niternochange parameter in neuralnetworkBaseMultilayerPerceptron
neuralnetworkMLPRegressor andneuralnetworkMLPClassifier to give control over
maximum number of epochs to not meet tol improvement 9456 by Nicholas Nadeau
•FIXFixed a bug in neuralnetworkBaseMultilayerPerceptron neuralnetwork
MLPRegressor andneuralnetworkMLPClassifier with newniternochange parameter
now at 10 from previously hardcoded 2 9456 by Nicholas Nadeau
•FIXFixed a bug in neuralnetworkMLPRegressor where fitting quit unexpectedly early due to local
minima or fluctuations 9456 by Nicholas Nadeau
sklearnpipeline
•FEATURE Thepredict method of pipelinePipeline now passes keyword arguments on to the
pipeline’s last estimator enabling the use of parameters such as returnstd in a pipeline with caution
9304 by Breno Freitas

•API C HANGE pipelineFeatureUnion now supports drop as a transformer to drop features 11144
by Thomas Fan
sklearnpreprocessing
•MAJOR FEATURE ExpandedpreprocessingOneHotEncoder to allow to encode categorical string
features as a numeric array using a onehot or dummy encoding scheme and added preprocessing
OrdinalEncoder to convert to ordinal integers Those two classes now handle encoding of all feature types
also handles stringvalued features and derives the categories based on the unique values in the features instead
of the maximum value in the features 9151 and 10521 by Vighnesh Birodkar and Joris Van den Bossche
•MAJOR FEATURE AddedpreprocessingKBinsDiscretizer for turning continuous features into cat
egorical or onehot encoded features 7668 9647 10195 10192 11272 11467 and 11505 by Henry
Lin Hanmin Qin Tom Dupre la Tour and Giovanni Giuseppe Costa
•MAJOR FEATURE AddedpreprocessingPowerTransformer which implements the YeoJohnson
and BoxCox power transformations Power transformations try to find a set of featurewise parametric trans
formations to approximately map data to a Gaussian distribution centered at zero and with unit variance This is
useful as a variancestabilizing transformation in situations where normality and homoscedasticity are desirable
10210 by Eric Chang and Maniteja Nandana and 11520 by Nicolas Hug
•MAJOR FEATURE NaN values are ignored and handled in the following preprocessing methods
preprocessingMaxAbsScaler preprocessingMinMaxScaler preprocessing
RobustScaler preprocessingStandardScaler preprocessingPowerTransformer
preprocessingQuantileTransformer classes and preprocessingmaxabsscale
preprocessingminmaxscale preprocessingrobustscale preprocessingscale
preprocessingpowertransform preprocessingquantiletransform functions respec
tively addressed in issues 11011 11005 11308 11206 11306 and 10437 By Lucija Gregov and
Guillaume Lemaitre
•FEATURE preprocessingPolynomialFeatures now supports sparse input 10452 by Aman
Dalmia and Joel Nothman
•FEATURE preprocessingRobustScaler andpreprocessingrobustscale can be fitted us
ing sparse matrices 11308 by Guillaume Lemaitre
•FEATURE preprocessingOneHotEncoder now supports the getfeaturenames method to obtain the
transformed feature names 10181 by Nirvan Anjirbag and Joris Van den Bossche
•FEATURE A parameter checkinverse was added to preprocessingFunctionTransformer to
ensure that func andinversefunc are the inverse of each other 9399 by Guillaume Lemaitre
•FEATURE Thetransform method ofsklearnpreprocessingMultiLabelBinarizer now ig
nores any unknown classes A warning is raised stating the unknown classes classes found which are ignored
10913 by Rodrigo Agundez
•FIXFixed bugs in preprocessingLabelEncoder which would sometimes throw errors when
transform orinversetransform was called with empty arrays 10458 by Mayur Kulkarni
•FIXFix ValueError in preprocessingLabelEncoder when using inversetransform on unseen
labels 9816 by Charlie Newey
•FIXFix bug inpreprocessingOneHotEncoder which discarded the dtype when returning a sparse
matrix output 11042 by Daniel Morales
•FIXFixfit andpartialfit inpreprocessingStandardScaler in the rare case when
withmeanFalse andwithstdFalse which was crashing by calling fit more than once and giving
inconsistent results for mean whether the input was a sparse or a dense matrix mean will be set to None

with both sparse and dense inputs nsamplesseen will be also reported for both input types 11235 by Guillaume Lemaitre

•API C HANGE Deprecate nvalues andcategoricalfeatures parameters and activefeatures featureindices andnvalues attributes of preprocessing OneHotEncoder Thenvalues parameter can be replaced with the new categories parameter and the attributes with the new categories attribute Selecting the categorical features with the categoricalfeatures parameter is now better supported using the compose ColumnTransformer 10521 by Joris Van den Bossche

•API C HANGE DeprecatepreprocessingImputer and move the corresponding module to impute SimpleImputer 9726 by Kumar Ashutosh

•API C HANGE Theaxis parameter that was in preprocessingImputer is no longer present in imputeSimpleImputer The behavior is equivalent to axis0 impute along columns Row wise imputation can be performed with FunctionTransformer eg FunctionTransformerlambda X SimpleImputerfittransformXTT 10829 by Guillaume Lemaitre and Gilberto Olimpio

•API C HANGE The NaN marker for the missing values has been changed between the preprocessing Imputer and the imputeSimpleImputer missingvaluesNaN should now be missingvaluesnpnan 11211 by Jeremie du Boisberranger

•API C HANGE InpreprocessingFunctionTransformer the default of validate will be from True toFalse in 022 10655 by Guillaume Lemaitre

sklearnsvm

•FIXFixed a bug in svmSVC where when the argument kernel is unicode in Python2 the predictproba method was raising an unexpected TypeError given dense inputs 10412 by Jiongyan Zhang

•API C HANGE Deprecaterandomstate parameter in svmOneClassSVM as the underlying implementation is not random 9497 by Albert Thomas

•API C HANGE The default value of gamma parameter of svmSVC NuSVC SVRNuSVR OneClassSVM will change from auto toscale in version 022 to account better for unscaled features 8361 by Gaurav Dhingra and Ting Neo

sklearntree

•ENHANCEMENT Although private and hence not assured API stability treecriterion ClassificationCriterion andtreecriterionRegressionCriterion may now be cimported and extended 10325 by Camil Staps

•FIXFixed a bug in treeBaseDecisionTree withsplitterbest where split threshold could become infinite when values in X were near infinite 10536 by Jonathan Ohayon

•FIXFixed a bug in treeMAE to ensure sample weights are being used during the calculation of tree MAE impurity Previous behaviour could cause suboptimal splits to be chosen since the impurity calculation considered all samples to be of equal weight importance 11464 by John Stott

sklearnutils

•FEATURE utilscheckarray andutilscheckXy now haveacceptlargesparse to control whether scipysparse matrices with 64bit indices should be rejected 11327 by Karan Dhingra and Joel Nothman

•EFFICIENCY F IXAvoid copying the data in utilscheckarray when the input data is a memmap and copyFalse 10663 by Arthur Mensch and Loïc Estève
•API C HANGE utilscheckarray yield aFutureWarning indicating that arrays of bytesstrings will be interpreted as decimal numbers beginning in version 022 10229 by Ryan Lee
Multiple modules
•FEATURE API C HANGE More consistent outlier detection API Add a scoresamples method insvmOneClassSVM ensembleIsolationForest neighborsLocalOutlierFactor covarianceEllipticEnvelope It allows to access raw score functions from original pa pers A new offset parameter allows to link scoresamples anddecisionfunction methods The contamination parameter of ensembleIsolationForest andneighbors LocalOutlierFactor decisionfunction methods is used to define this offset such that outliers resp inliers have negative resp positive decisionfunction values By default contamination is kept unchanged to 01 for a deprecation period In 022 it will be set to “auto” thus using methodspecific score offsets In covarianceEllipticEnvelope decisionfunction method the rawvalues parameter is deprecated as the shifted Mahalanobis distance will be always returned in 022 9015 by Nicolas Goix
•FEATURE API C HANGE Abehaviour parameter has been introduced in ensemble IsolationForest to ensure backward compatibility In the old behaviour the decisionfunction is independent of the contamination parameter A threshold attribute depending on the contamination parameter is thus used In the new behaviour the decisionfunction is dependent on the contamination parameter in such a way that 0 becomes its natural threshold to detect outliers Set ting behaviour to “old” is deprecated and will not be possible in version 022 Beside the behaviour parameter will be removed in 024 11553 by Nicolas Goix
•API C HANGE Added convergence warning to svmLinearSVC andlinearmodel LogisticRegression whenverbose is set to 0 10881 by Alexandre Sevin
•API C HANGE Changed warning type from UserWarning toexceptionsConvergenceWarning for failing convergence in linearmodellogisticregressionpath linearmodel RANSACRegressor linearmodelridgeregression gaussianprocess GaussianProcessRegressor gaussianprocessGaussianProcessClassifier decompositionfastica crossdecompositionPLSCanonical cluster AffinityPropagation andclusterBirch 10306 by Jonathan Siebert
Miscellaneous
•MAJOR FEATURE A new configuration parameter workingmemory was added to control memory con sumption limits in chunked operations such as the new metricspairwisedistanceschunked See Limiting Working Memory 10280 by Joel Nothman and Aman Dalmia
•FEATURE The version of joblib bundled with Scikitlearn is now 012 This uses a new default multiprocess ing implementation named loky While this may incur some memory and communication overhead it should provide greater crossplatform stability than relying on Python standard library multiprocessing 11741 by the Joblib developers especially Thomas Moreau and Olivier Grisel
•FEATURE An environment variable to use the site joblib instead of the vendored one was added Environment variables The main API of joblib is now exposed in sklearnutils 11166 by Gael Varoquaux
•FEATURE Add almost complete PyPy 3 support Known unsupported functionalities are datasets loadsvmlightfile featureextractionFeatureHasher andfeatureextraction textHashingVectorizer For running on PyPy PyPy3v510 Numpy 1140 and scipy 110 are required 11010 by Ronan Lamy and Roman Yurchak

•FEATURE A utility method sklearnshowversions was added to print out information relevant for debugging It includes the user system the Python executable the version of the main libraries and BLAS binding information 11596 by Alexandre Boucaud
•FIXFixed a bug when setting parameters on metaestimator involving both a wrapped estimator and its parameter 9999 by Marcus V oss and Joel Nothman
•FIXFixed a bug where calling sklearnbaseclone was not thread safe and could result in a “pop from empty list” error 9569 by Andreas Müller
•API C HANGE The default value of njobs is changed from 1toNone in all related functions and classes njobsNone meansunset It will generally be interpreted as njobs1 unless the current joblib Parallel backend context specifies otherwise See Glossary for additional information Note that this change happens immediately ie without a deprecation cycle 11741 by Olivier Grisel
•FIXFixed a bug in validation helpers where passing a Dask DataFrame results in an error 12462 by Zachariah Miller

1165 Changes to estimator checks

These changes mostly affect library developers
• Checks for transformers now apply if the estimator implements transform regardless of whether it inherits from sklearnbaseTransformerMixin 10474 by Joel Nothman
• Classifiers are now checked for consistency between decisionfunction and categorical predictions 10500 by Narine Kokhlikyan
• Allow tests in utilsestimatorcheckscheckestimator to test functions that accept pairwise data 9701 by Kyle Johnson
• Allowutilsestimatorcheckscheckestimator to check that there is no private settings apart from parameters during estimator initialization 9378 by Herilalaina Rakotoarison
• The set of checks in utilsestimatorcheckscheckestimator now includes a checksetparams test which checks that setparams is equivalent to passing parameters in init and warns if it encounters parameter validation 7738 by Alvin Chiang
• Add invariance tests for clustering metrics 8102 by Ankita Sinha and Guillaume Lemaitre
• Addcheckmethodssubsetinvariance tocheckestimator which checks that estimator methods are invariant if applied to a data subset 10428 by Jonathan Ohayon
• Add tests in utilsestimatorcheckscheckestimator to check that an estimator can handle readonly memmap input data 10663 by Arthur Mensch and Loïc Estève
•checksampleweightspandasseries now uses 8 rather than 6 samples to accommodate for the default number of clusters in clusterKMeans 10933 by Johannes Hansen
• Estimators are now checked for whether sampleweightNone equates to sampleweightnp ones 11558 by Sergul Aydore

July 2018

scikitlearn user guide Release 0213
This release is exclusively in order to support Python 37
Related changes
•niter may vary from previous releases in linearmodelLogisticRegression with
solverlbfgs andlinearmodelHuberRegressor For Scipy 100 the optimizer could
perform more than the requested maximum number of iterations Now both estimators will report at most
maxiter iterations even if more were performed 10723 by Joel Nothman
1172 Version 0191
October 23 2017
This is a bugfix release with some minor documentation improvements and enhancements to features released in
0190
Note there may be minor differences in TSNE output in this release due to 9623 in the case where multiple samples
have equal distance to some sample
Changelog
API changes
• Reverted the addition of metricsndcgscore andmetricsdcgscore which had been merged into
version 0190 by error The implementations were broken and undocumented
•returntrainscore which was added to modelselectionGridSearchCV
modelselectionRandomizedSearchCV andmodelselectioncrossvalidate in
version 0190 will be changing its default value from True to False in version 021 We found that calculating
training score could have a great effect on cross validation runtime in some cases Users should explicitly
setreturntrainscore to False if prediction or scoring functions are slow resulting in a deleterious
effect on CV runtime or to True if they wish to use the calculated scores 9677 by Kumar Ashutosh and Joel
Nothman
•correlationmodels andregressionmodels from the legacy gaussian processes implementation
have been belatedly deprecated 9717 by Kumar Ashutosh
Bug fixes
• Avoid integer overflows in metricsmatthewscorrcoef 9693 by Sam Steingold
• Fixed a bug in the objective function for manifoldTSNE both exact and with the BarnesHut approximation
whenncomponents 3 9711 by goncalorodrigues
• Fix regression in modelselectioncrossvalpredict where it raised an error with
methodpredictproba for some probabilistic classifiers 9641 by James Bourbeau
• Fixed a bug where datasetsmakeclassification modified its input weights 9865 by Sachin
Kelkar
•modelselectionStratifiedShuffleSplit now works with multioutput multiclass or multilabel
data with more than 1000 columns 9922 by Charlie Brummitt
• Fixed a bug with nested and conditional parameter setting eg setting a pipeline step and its parameter at the
same time 9945 by Andreas Müller and Joel Nothman

Regressions in 0190 fixed in 0191
• Fixed a bug where parallelised prediction in random forests was not threadsafe and could rarely result in arbitrary errors 9830 by Joel Nothman
• Fix regression in modelselectioncrossvalpredict where it no longer accepted Xas a list 9600 by Rasul Kerimov
• Fixed handling of crossvalpredict for binary classification with methoddecisionfunction 9593 by Reiichiro Nakano and core devs
• Fix regression in pipelinePipeline where it no longer accepted steps as a tuple 9604 by Joris Van den Bossche
• Fix bug where niter was not properly deprecated leaving niter unavailable for interim use inlinearmodelSGDClassifier linearmodelSGDRegressor linearmodel PassiveAggressiveClassifier linearmodelPassiveAggressiveRegressor and linearmodelPerceptron 9558 by Andreas Müller
• Dataset fetchers make sure temporary files are closed before removing them which caused errors on Windows 9847 by Joan Massich
• Fixed a regression in manifoldTSNE where it no longer supported metrics other than ‘euclidean’ and ‘pre computed’ 9623 by Oli Blum
Enhancements
• Our test suite and utilsestimatorcheckscheckestimators can now be run without Nose in stalled 9697 by Joan Massich
• To improve usability of version 019’s pipelinePipeline cachingmemory now allows joblib Memory instances This make use of the new utilsvalidationcheckmemory helper issue 9584 by Kumar Ashutosh
• Some fixes to examples 9750 9788 9815
• Made a FutureWarning in SGDbased estimators less verbose 9802 by Vrishank Bhardwaj

1173 Version 019
August 12 2017
Highlights
We are excited to release a number of great new features including neighborsLocalOutlierFactor for anomaly detection preprocessingQuantileTransformer for robust feature transformation and themultioutputClassifierChain metaestimator to simply account for dependencies between classes

in multilabel problems We have some new algorithms in existing estimators such as multiplicative up
date indecompositionNMF and multinomial linearmodelLogisticRegression with L1 loss use
solversaga
Cross validation is now able to return the results from multiple metric evaluations The new modelselection
crossvalidate can return many scores on the test data as well as training set performance and timings and we
have extended the scoring andrefit parameters for gridrandomized search to handle multiple metrics
You can also learn faster For instance the new option to cache transformations inpipelinePipeline makes
grid search over pipelines including slow transformations much more efficient And you can predict faster if you’re
sure you know what you’re doing you can turn off validating that the input is finite using configcontext
We’ve made some important fixes too We’ve fixed a longstanding implementation error in metrics
averageprecisionscore so please be cautious with prior results reported from that function A number
of errors in the manifoldTSNE implementation have been fixed particularly in the default BarnesHut approx
imationsemisupervisedLabelSpreading andsemisupervisedLabelPropagation have had
substantial fixes LabelPropagation was previously broken LabelSpreading should now correctly respect its alpha
parameter
Changed models
The following estimators and functions when fit with the same data and parameters may produce different models
from the previous version This often occurs due to changes in the modelling logic bug fixes or enhancements or in
random sampling procedures
•clusterKMeans with sparse X and initial centroids given bug fix
•crossdecompositionPLSRegression withscaleTrue bug fix
•ensembleGradientBoostingClassifier andensembleGradientBoostingRegressor
whereminimpuritysplit is used bug fix
• gradient boosting lossquantile bug fix
•ensembleIsolationForest bug fix
•featureselectionSelectFdr bug fix
•linearmodelRANSACRegressor bug fix
•linearmodelLassoLars bug fix
•linearmodelLassoLarsIC bug fix
•manifoldTSNE bug fix
•neighborsNearestCentroid bug fix
•semisupervisedLabelSpreading bug fix
•semisupervisedLabelPropagation bug fix
• tree based models where minweightfractionleaf is used enhancement
•modelselectionStratifiedKFold withshuffleTrue this change due to 7823 was not men
tioned in the release notes at the time
Details are listed in the changelog below
While we are trying to better inform users by providing this information we cannot assure that this list is complete

Changelog
New features
Classifiers and regressors
• AddedmultioutputClassifierChain for multilabel classification By Adam Kleczewski
• Added solver saga that implements the improved version of Stochastic Average Gradient in linearmodelLogisticRegression andlinearmodelRidge It allows the use of L1 penalty with multinomial logistic loss and behaves marginally better than 'sag' during the first epochs of ridge and logistic regression 8446 by Arthur Mensch
Other estimators
• Added the neighborsLocalOutlierFactor class for anomaly detection based on nearest neighbors 5279 by Nicolas Goix and Alexandre Gramfort
• Added preprocessingQuantileTransformer class and preprocessing quantiletransform function for features normalization based on quantiles 8363 by Denis Engemann Guillaume Lemaitre Olivier Grisel Raghav RV Thierry Guillemot and Gael Varoquaux
• The new solver mu implements a Multiplicate Update in decompositionNMF allowing the optimization of all betadivergences including the Frobenius norm the generalized KullbackLeibler divergence and the ItakuraSaito divergence 5295 by Tom Dupre la Tour
Model selection and evaluation
•modelselectionGridSearchCV andmodelselectionRandomizedSearchCV now support simultaneous evaluation of multiple metrics Refer to the Specifying multiple metrics for evaluation section of the user guide for more information 7388 by Raghav RV
• Added the modelselectioncrossvalidate which allows evaluation of multiple metrics This function returns a dict with more useful information from crossvalidation such as the train scores fit times and score times Refer to The crossvalidate function and multiple metric evaluation section of the userguide for more information 7388 by Raghav RV
• Addedmetricsmeansquaredlogerror which computes the mean square error of the logarithmic transformation of targets particularly useful for targets with an exponential trend 7655 by Karan Desai
• Addedmetricsdcgscore andmetricsndcgscore which compute Discounted cumulative gain DCG and Normalized discounted cumulative gain NDCG 7739 by David Gasquez
• Added the modelselectionRepeatedKFold andmodelselection RepeatedStratifiedKFold 8120 by Neeraj Gangwar
Miscellaneous
• Validation that input data contains no NaN or inf can now be suppressed using configcontext at your own risk This will save on runtime and may be particularly useful for prediction time 7548 by Joel Nothman
• Added a test to ensure parameter listing in docstrings match the functionclass signature 9206 by Alexandre Gramfort and Raghav RV
Enhancements
Trees and ensembles
• Theminweightfractionleaf constraint in tree construction is now more efficient taking a fast path to declare a node a leaf if its weight is less than 2 the minimum Note that the constructed tree will be different from previous versions where minweightfractionleaf is used 7441 by Nelson Liu

scikitlearn user guide Release 0213
•ensembleGradientBoostingClassifier andensembleGradientBoostingRegressor
now support sparse input for prediction 6101 by Ibraim Ganiev
•ensembleVotingClassifier now allows changing estimators by using ensemble
VotingClassifiersetparams An estimator can also be removed by setting it to None 7674 by
Yichuan Liu
•treeexportgraphviz now shows configurable number of decimal places 8698 by Guillaume
Lemaitre
• Addedflattentransform parameter to ensembleVotingClassifier to change output shape of
transform method to 2 dimensional 7794 by Ibraim Ganiev and Herilalaina Rakotoarison
Linear kernelized and related models
•linearmodelSGDClassifier linearmodelSGDRegressor linearmodel
PassiveAggressiveClassifier linearmodelPassiveAggressiveRegressor and
linearmodelPerceptron now expose maxiter andtol parameters to handle convergence more
preciselyniter parameter is deprecated and the fitted estimator exposes a niter attribute with actual
number of iterations before convergence 5036 by Tom Dupre la Tour
• Added average parameter to perform weight averaging in linearmodel
PassiveAggressiveClassifier 4939 by Andrea Esuli
•linearmodelRANSACRegressor no longer throws an error when calling fit if no inliers are found in
its first iteration Furthermore causes of skipped iterations are tracked in newly added attributes nskips
7914 by Michael Horrell
• IngaussianprocessGaussianProcessRegressor method predict is a lot faster with
returnstdTrue 8591 by Hadrien Bertrand
• Addedreturnstd topredict method oflinearmodelARDRegression andlinearmodel
BayesianRidge 7838 by Sergey Feldman
• Memory usage enhancements Prevent cast from float32 to float64 in linearmodel
MultiTaskElasticNet linearmodelLogisticRegression when using newtoncg solver and
linearmodelRidge when using svd sparsecg cholesky or lsqr solvers 8835 8061 by Joan Massich
and Nicolas Cordier and Thierry Guillemot
Other predictors
• Custom metrics for the neighbors binary trees now have fewer constraints they must take two 1darrays and
return a float 6288 by Jake Vanderplas
•algorithmauto inneighbors estimators now chooses the most appropriate algorithm for all input
types and metrics 9145 by Herilalaina Rakotoarison and Reddy Chinthala
Decomposition manifold learning and clustering
•clusterMiniBatchKMeans andclusterKMeans now use significantly less memory when assigning
data points to their nearest cluster center 7721 by Jon Crall
•decompositionPCA decompositionIncrementalPCA anddecomposition
TruncatedSVD now expose the singular values from the underlying SVD They are stored in the
attributesingularvalues like indecompositionIncrementalPCA 7685 by Tommy Löfstedt
•decompositionNMF now faster when betaloss0 9277 by hongkahjun
• Memory improvements for method barneshut inmanifoldTSNE 7089 by Thomas Moreau and Olivier
Grisel
• Optimization schedule improvements for BarnesHut manifoldTSNE so the results are closer to the one
from the reference implementation lvdmaatenbhtsne by Thomas Moreau and Olivier Grisel

• Memory usage enhancements Prevent cast from float32 to float64 in decompositionPCA and decompositionrandomizedsvdlowrank 9067 by Raghav RV

Preprocessing and feature selection

• Addednormorder parameter to featureselectionSelectFromModel to enable selection of the norm order when coef is more than 1D 6181 by Antoine Wendlinger
• Added ability to use sparse matrices in featureselectionfregression withcenterTrue 8065 by Daniel LeJeune
• Small performance improvement to ngram creation in featureextractiontext by binding methods for loops and specialcasing unigrams 7567 by Jaye Doepke
• Relax assumption on the data for the kernelapproximationSkewedChi2Sampler Since the SkewedChi2 kernel is defined on the open interval −□□□□□□□□□□ ∞□ the transform function should not check whether X 0 but whether X selfskewedness 7573 by Romain Brault
• Made default kernel parameters kerneldependent in kernelapproximationNystroem 5229 by Saurabh Bansod and Andreas Müller

Model evaluation and metaestimators

•pipelinePipeline is now able to cache transformers within a pipeline by using the memory constructor parameter 7990 by Guillaume Lemaitre
•pipelinePipeline steps can now be accessed as attributes of its namedsteps attribute 8586 by Herilalaina Rakotoarison
• Addedsampleweight parameter to pipelinePipelinescore 7723 by Mikhail Korobov
• Added ability to set njobs parameter to pipelinemakeunion ATypeError will be raised for any other kwargs 8028 by Alexander Booth
•modelselectionGridSearchCV modelselectionRandomizedSearchCV and modelselectioncrossvalscore now allow estimators with callable kernels which were previously prohibited 8005 by Andreas Müller
•modelselectioncrossvalpredict now returns output of the correct shape for all values of the argumentmethod 7863 by Aman Dalmia
• Addedshuffle andrandomstate parameters to shuffle training data before taking prefixes of it based on training sizes in modelselectionlearningcurve 7506 by Narine Kokhlikyan
•modelselectionStratifiedShuffleSplit now works with multioutput multiclass or multilabel data 9044 by Vlad Niculae
• Speed improvements to modelselectionStratifiedShuffleSplit 5991 by Arthur Mensch and Joel Nothman
• Addshuffle parameter to modelselectiontraintestsplit 8845 by themrmax
•multioutputMultiOutputRegressor andmultioutputMultiOutputClassifier now support online learning using partialfit issue8053 by Peng Yu
• Addmaxtrainsize parameter to modelselectionTimeSeriesSplit 8282 by Aman Dalmia
• More clustering metrics are now available through metricsgetscorer andscoring parameters 8117 by Raghav RV
• A scorer based on metricsexplainedvariancescore is also available 9259 by Hanmin Qin

Metrics

•metricsmatthewscorrcoef now support multiclass classification 8094 by Jon Crall

• Addsampleweight parameter to metricscohenkappascore 8335 by Victor Poughon
Miscellaneous
•utilscheckestimator now attempts to ensure that methods transform predict etc do not set attributes on the estimator 7533 by Ekaterina Krivich
• Added type checking to the acceptsparse parameter in utilsvalidation methods This parameter now accepts only boolean string or listtuple of strings acceptsparseNone is deprecated and should be replaced by acceptsparseFalse 7880 by Josh Karnofsky
• Make it possible to load a chunk of an svmlight formatted file by passing a range of bytes to datasets loadsvmlightfile 935 by Olivier Grisel
•dummyDummyClassifier anddummyDummyRegressor now accept nonfinite features 8931 by Attractadore
Bug fixes
Trees and ensembles
• Fixed a memory leak in trees when using trees with criterionmae 8002 by Raghav RV
• Fixed a bug where ensembleIsolationForest uses an an incorrect formula for the average path length 8549 by Peter Wang
• Fixed a bug where ensembleAdaBoostClassifier throwsZeroDivisionError while fitting data with single class labels 7501 by Dominik Krzeminski
• Fixed a bug in ensembleGradientBoostingClassifier andensemble GradientBoostingRegressor where a float being compared to 00 usingcaused a divide by zero error 7970 by He Chen
• Fix a bug where ensembleGradientBoostingClassifier andensemble GradientBoostingRegressor ignored the minimpuritysplit parameter 8006 by Sebastian Pölsterl
• Fixedoobscore inensembleBaggingClassifier 8936 by Michael Lewis
• Fixed excessive memory usage in prediction for random forests estimators 8672 by Mike Benfield
• Fixed a bug where sampleweight as a list broke random forests in Python 2 8068 by xor
• Fixed a bug where ensembleIsolationForest fails when maxfeatures is less than 1 5732 by Ishank Gulati
• Fix a bug where gradient boosting with lossquantile computed negative errors for negative values of ytrue ypred leading to wrong values when calling call 8087 by Alexis Mignon
• Fix a bug where ensembleVotingClassifier raises an error when a numpy array is passed in for weights 7983 by Vincent Pham
• Fixed a bug where treeexportgraphviz raised an error when the length of featuresnames does not match nfeatures in the decision tree 8512 by Li Li
Linear kernelized and related models
• Fixed a bug where linearmodelRANSACRegressorfit may run until maxiter if it finds a large inlier group early 8251 by aivision2020
• Fixed a bug where naivebayesMultinomialNB andnaivebayesBernoulliNB failed when alpha0 5814 by Yichuan Liu and Herilalaina Rakotoarison

• Fixed a bug where linearmodelLassoLars does not give the same result as the LassoLars implemen
tation available in R lars library 7849 by Jair Montoya Martinez
• Fixed a bug in linearmodelRandomizedLasso linearmodelLars linearmodel
LassoLars linearmodelLarsCV andlinearmodelLassoLarsCV where the parameter
precompute was not used consistently across classes and some values proposed in the docstring could raise
errors 5359 by Tom Dupre la Tour
• Fix inconsistent results between linearmodelRidgeCV andlinearmodelRidge when using
normalizeTrue 9302 by Alexandre Gramfort
• Fix a bug where linearmodelLassoLarsfit sometimes left coef as a list rather than an ndarray
8160 by CJ Carey
• FixlinearmodelBayesianRidgefit to return ridge parameter alpha andlambda consistent
with calculated coefficients coef andintercept 8224 by Peter Gedeck
• Fixed a bug in svmOneClassSVM where it returned floats instead of integer classes 8676 by Vathsala
Achar
• Fix AICBIC criterion computation in linearmodelLassoLarsIC 9022 by Alexandre Gramfort and
Mehmet Basbug
• Fixed a memory leak in our LibLinear implementation 9024 by Sergei Lebedev
• Fix bug where stratified CV splitters did not work with linearmodelLassoCV 8973 by Paulo Haddad
• Fixed a bug in gaussianprocessGaussianProcessRegressor when the standard deviation and
covariance predicted without fit would fail with a unmeaningful error by default 6573 by Quazi Marufur
Rahman and Manoj Kumar
Other predictors
• FixsemisupervisedBaseLabelPropagation to correctly implement LabelPropagation and
LabelSpreading as done in the referenced papers 9239 by Andre Ambrosio Boechat Utkarsh Upadhyay
and Joel Nothman
Decomposition manifold learning and clustering
• Fixed the implementation of manifoldTSNE
•earlyexageration parameter had no effect and is now used for the first 250 optimization iterations
• Fixed the AssertionError Tree consistency failed exception reported in 8992
• Improve the learning schedule to match the one from the reference implementation lvdmaatenbhtsne by
Thomas Moreau and Olivier Grisel
• Fix a bug in decompositionLatentDirichletAllocation where theperplexity method was
returning incorrect results because the transform method returns normalized document topic distributions as
of version 018 7954 by Gary Foreman
• Fix output shape and bugs with njobs 1 in decompositionSparseCoder transform and
decompositionsparseencode for onedimensional data and one component This also impacts the
output shape of decompositionDictionaryLearning 8086 by Andreas Müller
• Fixed the implementation of explainedvariance indecompositionPCA decomposition
RandomizedPCA anddecompositionIncrementalPCA 9105 by Hanmin Qin
• Fixed the implementation of noisevariance indecompositionPCA 9108 by Hanmin Qin
• Fixed a bug where clusterDBSCAN gives incorrect result when input is a precomputed sparse matrix with
initial rows all zero 8306 by Akshay Gupta

• Fix a bug regarding fitting clusterKMeans with a sparse array X and initial centroids where X's means were unnecessarily being subtracted from the centroids 7872 by Josh Karnofsky
• Fixes to the input validation in covarianceEllipticEnvelope 8086 by Andreas Müller
• Fixed a bug in covarianceMinCovDet where inputting data that produced a singular covariance matrix would cause the helper method cstep to throw an exception 3367 by Jeremy Steward
• Fixed a bug in manifoldTSNE affecting convergence of the gradient descent 8768 by David DeTomaso
• Fixed a bug in manifoldTSNE where it stored the incorrect kldivergence 6507 by Sebastian Saeger
• Fixed improper scaling in crossdecompositionPLSRegression withscaleTrue 7819 by jayzed82
•clusterbiclusterSpectralCoclustering and clusterbicluster SpectralBiclustering fit method conforms with API by accepting yand returning the object 6126 7814 by Laurent Direr and Maniteja Nandana
• Fix bug where mixturesample methods did not return as many samples as requested 7702 by Levi John Wolf
• Fixed the shrinkage implementation in neighborsNearestCentroid 9219 by Hanmin Qin

Preprocessing and feature selection

• For sparse matrices preprocessingnormalize withreturnnormTrue will now raise a NotImplementedError with 'l1' or 'l2' norm and with norm 'max' the norms returned will be the same as for dense matrices 7771 by Ang Lu
• Fix a bug where featureselectionSelectFdr did not exactly implement BenjaminiHochberg pro cedure It formerly may have selected fewer features than it should 7490 by Peng Meng
• Fixed a bug where linearmodelRandomizedLasso andlinearmodel RandomizedLogisticRegression breaks for sparse input 8259 by Aman Dalmia
• Fix a bug where featureextractionFeatureHasher mandatorily applied a sparse random projec tion to the hashed features preventing the use of featureextractiontextHashingVectorizer in a pipeline with featureextractiontextTfidfTransformer 7565 by Roman Yurchak
• Fix a bug where featureselectionmutualinforegression did not correctly use nneighbors 8181 by Guillaume Lemaitre

Model evaluation and metaestimators

• Fixed a bug where modelselectionBaseSearchCVinversetransform re turnsselfbestestimatortransform instead of selfbestestimator inversetransform 8344 by Akshay Gupta and Rasmus Eriksson
• Added classes attribute to modelselectionGridSearchCV modelselection RandomizedSearchCV gridsearchGridSearchCV and gridsearch RandomizedSearchCV that matches the classes attribute of bestestimator 7661 and 8295 by Alyssa Batula Dylan WernerMeier and Stephen Hoover
• Fixed a bug where modelselectionvalidationcurve reused the same estimator for each parame ter value 7365 by Aleksandr Sandrovskii
•modelselectionpermutationtestscore now works with Pandas types 5697 by Stijn Tonk
• Several fixes to input validation in multiclassOutputCodeClassifier 8086 by Andreas Müller
•multiclassOneVsOneClassifier 'spartialfit now ensures all classes are provided upfront 6250 by Asish Panda

• FixmultioutputMultiOutputClassifierpredictproba to return a list of 2d arrays rather
than a 3d array In the case where different target columns had different numbers of classes a ValueError
would be raised on trying to stack matrices with different dimensions 8093 by Peter Bull
• Cross validation now works with Pandas datatypes that that have a readonly index 9507 by Loic Esteve
Metrics
•metricsaverageprecisionscore no longer linearly interpolates between operating points and in
stead weighs precisions by the change in recall since the last operating point as per the Wikipedia entry 7356
By Nick Dingwall and Gael Varoquaux
• Fix a bug in metricsclassificationchecktargets which would return binary ifytrue
andypred were bothbinary but the union of ytrue andypred wasmulticlass 8377 by
Loic Esteve
• Fixed an integer overflow bug in metricsconfusionmatrix and hence metrics
cohenkappascore 8354 7929 by Joel Nothman and Jon Crall
• Fixed passing of gamma parameter to the chi2 kernel inmetricspairwisepairwisekernels
5211 by Nick Rhinehart Saurabh Bansod and Andreas Müller
Miscellaneous
• Fixed a bug when datasetsmakeclassification fails when generating more than 30 features 8159
by Herilalaina Rakotoarison
• Fixed a bug where datasetsmakemoons gives an incorrect result when nsamples is odd 8198 by
Josh Levy
• Somefetch functions in datasets were ignoring the downloadifmissing keyword 7944 by
Ralf Gommers
• Fix estimators to accept a sampleweight parameter of type pandasSeries in theirfit function
7825 by Kathleen Chen
• Fix a bug in cases where numpycumsum may be numerically unstable raising an exception if instability is
identified 7376 and 7331 by Joel Nothman and yangarbiter
• Fix a bug where baseBaseEstimatorgetstate obstructed pickling customizations of child
classes when used in a multiple inheritance context 8316 by Holger Peters
• Update SphinxGallery from 014 to 017 for resolving links in documentation build with Sphinx15 8010
7986 by Oscar Najera
• Adddatahome parameter to sklearndatasetsfetchkddcup99 9289 by Loic Esteve
• Fix dataset loaders using Python 3 version of makedirs to also work in Python 2 9284 by Sebastin Santy
• Several minor issues were fixed with thanks to the alerts of lgtmcomhttpslgtmcom 9278 by Jean Helie
among others
API changes summary
Trees and ensembles
• Gradient boosting base models are no longer estimators By Andreas Müller
• All tree based estimators now accept a minimpuritydecrease parameter in lieu of the
minimpuritysplit which is now deprecated The minimpuritydecrease helps stop
splitting the nodes in which the weighted impurity decrease from splitting is no longer at least
minimpuritydecrease 8449 by Raghav RV

scikitlearn user guide Release 0213
Linear kernelized and related models
•niter parameter is deprecated in linearmodelSGDClassifier linearmodel
SGDRegressor linearmodelPassiveAggressiveClassifier linearmodel
PassiveAggressiveRegressor andlinearmodelPerceptron By Tom Dupre la Tour
Other predictors
•neighborsLSHForest has been deprecated and will be removed in 021 due to poor performance 9078
by Laurent Direr
•neighborsNearestCentroid no longer purports to support metricprecomputed which now
raises an error 8515 by Sergul Aydore
• Thealpha parameter of semisupervisedLabelPropagation now has no effect and is deprecated
to be removed in 021 9239 by Andre Ambrosio Boechat Utkarsh Upadhyay and Joel Nothman
Decomposition manifold learning and clustering
• Deprecate the doctopicdistr argument of the perplexity method in decomposition
LatentDirichletAllocation because the user no longer has access to the unnormalized document topic
distribution needed for the perplexity calculation 7954 by Gary Foreman
• Thentopics parameter of decompositionLatentDirichletAllocation has been renamed to
ncomponents and will be removed in version 021 8922 by Attractadore
•decompositionSparsePCAtransform ’sridgealpha parameter is deprecated in preference for
class parameter 8137 by Naoya Kanai
•clusterDBSCAN now has ametricparams parameter 8139 by Naoya Kanai
Preprocessing and feature selection
•featureselectionSelectFromModel now has apartialfit method only if the underlying es
timator does By Andreas Müller
•featureselectionSelectFromModel now validates the threshold parameter and sets the
threshold attribute during the call to fit and no longer during the call to transform By Andreas
Müller
• Thenonnegative parameter in featureextractionFeatureHasher has been deprecated and
replaced with a more principled alternative alternatesign 7565 by Roman Yurchak
•linearmodelRandomizedLogisticRegression andlinearmodelRandomizedLasso
have been deprecated and will be removed in version 021 8995 by RamanaS
Model evaluation and metaestimators
• Deprecate the fitparams constructor input to the modelselectionGridSearchCV and
modelselectionRandomizedSearchCV in favor of passing keyword parameters to the fit methods
of those classes Datadependent parameters needed for model training should be passed as keyword arguments
tofit and conforming to this convention will allow the hyperparameter selection classes to be used with tools
such asmodelselectioncrossvalpredict 2879 by Stephen Hoover
• In version 021 the default behavior of splitters that use the testsize andtrainsize parameter will
change such that specifying trainsize alone will cause testsize to be the remainder 7459 by Nelson
Liu
•multiclassOneVsRestClassifier now has partialfit decisionfunction and
predictproba methods only when the underlying estimator does 7812 by Andreas Müller and Mikhail
Korobov
•multiclassOneVsRestClassifier now has apartialfit method only if the underlying estima
tor does By Andreas Müller

• Thedecisionfunction output shape for binary classification in multiclass
OneVsRestClassifier andmulticlassOneVsOneClassifier is nownsamples to
conform to scikitlearn conventions 9100 by Andreas Müller
• ThemultioutputMultiOutputClassifierpredictproba function used to return a 3d array
nsamples nclasses noutputs In the case where different target columns had different numbers
of classes a ValueError would be raised on trying to stack matrices with different dimensions This func
tion now returns a list of arrays where the length of the list is noutputs and each array is nsamples
nclasses for that particular output 8093 by Peter Bull
• Replace attribute namedsteps dict toutilsBunch inpipelinePipeline to enable tab com
pletion in interactive environment In the case conflict value on namedsteps anddict attributedict
behavior will be prioritized 8481 by Herilalaina Rakotoarison
Miscellaneous
• Deprecate the yparameter in transform andinversetransform The method should not accept y
parameter as it’s used at the prediction time 8174 by Tahar Zanouda Alexandre Gramfort and Raghav RV
• SciPy 0133 and NumPy 182 are now the minimum supported versions for scikitlearn The following
backported functions in utils have been removed or deprecated accordingly 8854 and 8874 by Naoya
Kanai
• Thestorecovariances andcovariances parameters of discriminantanalysis
QuadraticDiscriminantAnalysis has been renamed to storecovariance andcovariance
to be consistent with the corresponding parameter names of the discriminantanalysis
LinearDiscriminantAnalysis They will be removed in version 021 7998 by Jiacheng
Removed in 019
–utilsfixesargpartition
–utilsfixesarrayequal
–utilsfixesastype
–utilsfixesbincount
–utilsfixesexpit

scikitlearn user guide Release 0213
–utilsrandomchoice
–utilssparsetoolsconnectedcomponents
–utilsstatsrankdata
• Estimators with both methods decisionfunction andpredictproba are now required to have a monotonic relation between them The method checkdecisionprobaconsistency has been added inutilsestimatorchecks to check their consistency 7578 by Shubham Bhardwaj
• All checks in utilsestimatorchecks in particular utilsestimatorchecks checkestimator now accept estimator instances Most other checks do not accept estimator classes any more 9019 by Andreas Müller
• Ensure that estimators' attributes ending with are not set in the constructor but only in the fit method Most notably ensemble estimators deriving from ensembleBaseEnsemble now only have self estimators available after fit 7464 by Lars Buitinck and Loic Esteve

Code and Documentation Contributors

Thanks to everyone who has contributed to the maintenance and improvement of the project since version 018 in cluding

1174 Version 0182
June 20 2017
Last release with Python 26 support
Scikitlearn 018 is the last major release of scikitlearn to support Python 26 Later versions of scikitlearn will require Python 27 or above
Changelog
• Fixes for compatibility with NumPy 1130 7946 8355 by Loic Esteve
• Minor compatibility changes in the examples 9010 8040 9149
Code Contributors
Aman Dalmia Loic Esteve Nate Guerin Sergei Lebedev
1175 Version 0181
November 11 2016
Changelog
Enhancements
• Improved samplewithoutreplacement speed by utilizing numpyrandompermutation for most cases
As a result samples may differ in this release for a fixed random state Affected estimators
–ensembleBaggingClassifier
–ensembleBaggingRegressor
–linearmodelRANSACRegressor
–modelselectionRandomizedSearchCV
–randomprojectionSparseRandomProjection
This also affects the datasetsmakeclassification method

Bug fixes
• Fix issue where mingradnorm andniterwithoutprogress parameters were not being utilised bymanifoldTSNE 6497 by Sebastian Säger
• Fix bug for svm's decision values when decisionfunctionshape isovr insvmSVC svmSVC 's decisionfunction was incorrect from versions 0170 through 0180 7724 by Bing Tian Dai
• Attribute explainedvarianceratio of discriminantanalysis LinearDiscriminantAnalysis calculated with SVD and Eigen solver are now of the same length 7632 by JPFrancoia
• Fixes issue in Univariate feature selection where score functions were not accepting multilabel targets 7676 by Mohammed Affan
• Fixed setting parameters when calling fit multiple times on featureselectionSelectFromModel 7756 by Andreas Müller
• Fixes issue in partialfit method ofmulticlassOneVsRestClassifier when number of classes used inpartialfit was less than the total number of classes in the data 7786 by Srivatsan Ramesh
• Fixes issue in calibrationCalibratedClassifierCV where the sum of probabilities of each class for a data was not 1 and CalibratedClassifierCV now handles the case where the training set has less number of classes than the total data 7799 by Srivatsan Ramesh
• Fix a bug where sklearnfeatureselectionSelectFdr did not exactly implement Benjamini Hochberg procedure It formerly may have selected fewer features than it should 7490 by Peng Meng
•sklearnmanifoldLocallyLinearEmbedding now correctly handles integer inputs 6282 by Jake Vanderplas
• Theminweightfractionleaf parameter of treebased classifiers and regressors now assumes uniform sample weights by default if the sampleweight argument is not passed to the fit function Previously the parameter was silently ignored 7301 by Nelson Liu
• Numerical issue with linearmodelRidgeCV on centered data when nfeatures nsamples 6178 by Bertrand Thirion
• Tree splitting criterion classes' cloningpickling is now memory safe 7680 by Ibraim Ganiev
• Fixed a bug where decompositionNMF sets itsniters attribute in transform 7553 by Ekate rina Krivich
•sklearnlinearmodelLogisticRegressionCV now correctly handles string labels 5874 by Raghav RV
• Fixed a bug where sklearnmodelselectiontraintestsplit raised an error when stratify is a list of string labels 7593 by Raghav RV
• Fixed a bug where sklearnmodelselectionGridSearchCV andsklearn modelselectionRandomizedSearchCV were not pickleable because of a pickling bug in np maMaskedArray 7594 by Raghav RV
• All crossvalidation utilities in sklearnmodelselection now permit one time crossvalidation splitters for thecvparameter Also nondeterministic crossvalidation splitters where multiple calls to split produce dissimilar splits can be used as cvparameter The sklearnmodelselectionGridSearchCV will crossvalidate each parameter setting on the split produced by the first split call to the crossvalidation splitter 7660 by Raghav RV
• Fix bug where preprocessingMultiLabelBinarizerfittransform returned an invalid CSR matrix 7750 by CJ Carey

• Fixed a bug where metricspairwisecosinedistances could return a small negative distance
7732 by Artsion
API changes summary
Trees and forests
• Theminweightfractionleaf parameter of treebased classifiers and regressors now assumes uniform
sample weights by default if the sampleweight argument is not passed to the fit function Previously the
parameter was silently ignored 7301 by Nelson Liu
• Tree splitting criterion classes' cloningpickling is now memory safe 7680 by Ibraim Ganiev
Linear kernelized and related models
• Length of explainedvarianceratio ofdiscriminantanalysis
LinearDiscriminantAnalysis changed for both Eigen and SVD solvers The attribute has now
a length of minncomponents nclasses 1 7632 by JPFrancoia
• Numerical issue with linearmodelRidgeCV on centered data when nfeatures nsamples
6178 by Bertrand Thirion
1176 Version 018
September 28 2016
Last release with Python 26 support
Scikitlearn 018 will be the last version of scikitlearn to support Python 26 Later versions of scikitlearn will
require Python 27 or above
Model Selection Enhancements and API Changes
•The modelselection module
The new module sklearnmodelselection which groups together the functionalities of formerly
sklearncrossvalidation sklearngridsearch andsklearnlearningcurve intro
duces new possibilities such as nested crossvalidation and better manipulation of parameter searches with Pan
das
Many things will stay the same but there are some key differences Read below to know more about the changes
•Dataindependent CV splitters enabling nested crossvalidation
The new crossvalidation splitters defined in the sklearnmodelselection are no longer initialized
with any datadependent parameters such as y Instead they expose a split method that takes in the data and
yields a generator for the different splits
This change makes it possible to use the crossvalidation splitters to perform nested crossvalidation facilitated
bymodelselectionGridSearchCV andmodelselectionRandomizedSearchCV utilities
•The enhanced cvresults attribute
The newcvresults attribute of modelselectionGridSearchCV andmodelselection
RandomizedSearchCV introduced in lieu of the gridscores attribute is a dict of 1D arrays with
elements in each array corresponding to the parameter settings ie search candidates

Thecvresults dict can be easily imported into pandas as aDataFrame for exploring the search results
Thecvresults arrays include scores for each crossvalidation split with keys such as
split0testscore as well as their mean meantestscore and standard deviation
stdtestscore
The ranks for the search candidates based on their mean crossvalidation score is available at
cvresultsranktestscore
The parameter values for each parameter is stored separately as numpy masked object arrays The value for
that search candidate is masked if the corresponding parameter is not applicable Additionally a list of all the
parameter dicts are stored at cvresultsparams
•Parameters nfolds and niter renamed to nsplits
Some parameter names have changed The nfolds parameter in new modelselectionKFold
modelselectionGroupKFold see below for the name change and modelselection
StratifiedKFold is now renamed to nsplits Theniter parameter in modelselection
ShuffleSplit the new class modelselectionGroupShuffleSplit andmodelselection
StratifiedShuffleSplit is now renamed to nsplits
•Rename of splitter classes which accepts group labels along with data
The crossvalidation splitters LabelKFold LabelShuffleSplit LeaveOneLabelOut and
LeavePLabelOut have been renamed to modelselectionGroupKFold modelselection
GroupShuffleSplit modelselectionLeaveOneGroupOut andmodelselection
LeavePGroupsOut respectively
Note the change from singular to plural form in modelselectionLeavePGroupsOut
•Fit parameter labels renamed to groups
Thelabels parameter in the split method of the newly renamed splitters modelselection
GroupKFold modelselectionLeaveOneGroupOut modelselection
LeavePGroupsOut modelselectionGroupShuffleSplit is renamed to groups following the
new nomenclature of their class names
•Parameter nlabels renamed to ngroups
The parameter nlabels in the newly renamed modelselectionLeavePGroupsOut is changed to
ngroups
• Training scores and Timing information
cvresults also includes the training scores for each crossvalidation split with keys such
assplit0trainscore as well as their mean meantrainscore and stan
dard deviation stdtrainscore To avoid the cost of evaluating training score set
returntrainscoreFalse
Additionally the mean and standard deviation of the times taken to split train and score the model across all the
crossvalidation splits is available at the key meantime andstdtime respectively
Changelog
New features
Classifiers and Regressors
• The Gaussian Process module has been reimplemented and now offers classification and regression esti
mators through gaussianprocessGaussianProcessClassifier andgaussianprocess
GaussianProcessRegressor Among other things the new implementation supports kernel engineering

gradientbased hyperparameter optimization or sampling of functions from GP prior and GP posterior Extensive documentation and examples are provided By Jan Hendrik Metzen
• Added new supervised learning algorithm Multilayer Perceptron 3204 by Issam H Laradji
• AddedlinearmodelHuberRegressor a linear model robust to outliers 5291 by Manoj Kumar
• Added the multioutputMultiOutputRegressor metaestimator It converts single output regressors to multioutput regressors by fitting one regressor per output By Tim Head

Other estimators

• NewmixtureGaussianMixture andmixtureBayesianGaussianMixture replace former mixture models employing faster inference for sounder results 7295 by Wei Xue and Thierry Guillemot
• ClassdecompositionRandomizedPCA is now factored into decompositionPCA and it is available calling with parameter svdsolverrandomized The default number of niter for randomized has changed to 4 The old behavior of PCA is recovered by svdsolverfull An additional solver calls arpack and performs truncated nonrandomized SVD By default the best solver is selected depending on the size of the input and the number of components requested 5299 by Giorgio Patrini
• Added two functions for mutual information estimation featureselection mutualinfoclassif andfeatureselectionmutualinforegression These functions can be used in featureselectionSelectKBest andfeatureselection SelectPercentile as score functions By Andrea Bravi and Nikolay Mayorov
• Added the ensembleIsolationForest class for anomaly detection based on random forests By Nicolas Goix
• Addedalgorithmelkan toclusterKMeans implementing Elkan's fast KMeans algorithm By Andreas Müller

Model selection and evaluation

• Addedmetricsclusterfowlkesmallowsscore the Fowlkes Mallows Index which measures the similarity of two clusterings of a set of points By Arnaud Fouchet and Thierry Guillemot
• Addedmetricscalinskiharabazscore which computes the Calinski and Harabaz score to evaluate the resulting clustering of a set of points By Arnaud Fouchet and Thierry Guillemot
• Added new crossvalidation splitter modelselectionTimeSeriesSplit to handle time series data 6586 by YenChen Lin
• The crossvalidation iterators are replaced by crossvalidation splitters available from sklearn modelselection allowing for nested crossvalidation See Model Selection Enhancements and API Changes for more information 4294 by Raghav RV

Enhancements

Trees and ensembles

• Added a new splitting criterion for treeDecisionTreeRegressor the mean absolute error This criterion can also be used in ensembleExtraTreesRegressor ensemble RandomForestRegressor and the gradient boosting estimators 6667 by Nelson Liu
• Added weighted impuritybased early stopping criterion for decision tree growth 6954 by Nelson Liu
• The random forest extra tree and decision tree estimators now has a method decisionpath which returns the decision path of samples in the tree By Arnaud Joly
• A new example has been added unveiling the decision tree structure By Arnaud Joly

• Random forest extra trees decision trees and gradient boosting estimator accept the parameter minsamplessplit andminsamplesleaf provided as a percentage of the training samples By yelite and Arnaud Joly
• Gradient boosting estimators accept the parameter criterion to specify to splitting criterion used in built decision trees 6667 by Nelson Liu
• The memory footprint is reduced sometimes greatly for ensemblebaggingBaseBagging and classes that inherit from it ie ensembleBaggingClassifier ensembleBaggingRegressor and ensembleIsolationForest by dynamically generating attribute estimatorssamples only when it is needed By David Staub
• Addednjobs andsampleweight parameters for ensembleVotingClassifier to fit underlying estimators in parallel 5805 by Ibraim Ganiev

Linear kernelized and related models

• InlinearmodelLogisticRegression the SAG solver is now available in the multinomial case 5251 by Tom Dupre la Tour
•linearmodelRANSACRegressor svmLinearSVC andsvmLinearSVR now support sampleweight By Imaculate
• Add parameter loss tolinearmodelRANSACRegressor to measure the error on the samples for every trial By Manoj Kumar
• Prediction of outofsample events with Isotonic Regression isotonicIsotonicRegression is now much faster over 1000x in tests with synthetic data By Jonathan Arfa
• Isotonic regression isotonicIsotonicRegression now uses a better algorithm to avoid On2 behavior in pathological cases and is also generally faster 6691 By Antony Lee
•naivebayesGaussianNB now accepts dataindependent classpriors through the parameter priors By Guillaume Lemaitre
•linearmodelElasticNet andlinearmodelLasso now works with npfloat32 input data without converting it into npfloat64 This allows to reduce the memory consumption 6913 by YenChen Lin
•semisupervisedLabelPropagation andsemisupervisedLabelSpreading now accept arbitrary kernel functions in addition to strings knn andrbf 5762 by Utkarsh Upadhyay

Decomposition manifold learning and clustering

• Addedinversetransform function to decompositionNMF to compute data matrix of original shape By Anish Shah
•clusterKMeans andclusterMiniBatchKMeans now works with npfloat32 andnp float64 input data without converting it This allows to reduce the memory consumption by using np float32 6846 by Sebastian Säger and YenChen Lin

Preprocessing and feature selection

•preprocessingRobustScaler now accepts quantilerange parameter 5929 by Konstantin Pod shumok
•featureextractionFeatureHasher now accepts string values 6173 by Ryad Zenine and Devashish Deshpande
• Keyword arguments can now be supplied to func inpreprocessingFunctionTransformer by means of the kwargs parameter By Brian McFee
•featureselectionSelectKBest andfeatureselectionSelectPercentile now accept score functions that take X y as input and return only the scores By Nikolay Mayorov

Model evaluation and metaestimators
•multiclassOneVsOneClassifier andmulticlassOneVsRestClassifier now support
partialfit By Asish Panda and Philipp Dowling
• Added support for substituting or disabling pipelinePipeline andpipelineFeatureUnion com
ponents using the setparams interface that powers sklearngridsearch See Selecting dimension
ality reduction with Pipeline and GridSearchCV By Joel Nothman and Robert McGibbon
• The new cvresults attribute of modelselectionGridSearchCV andmodelselection
RandomizedSearchCV can be easily imported into pandas as a DataFrame Ref Model Selection En
hancements and API Changes for more information 6697 by Raghav RV
• Generalization of modelselectioncrossvalpredict One can pass method names such as pre
dictproba to be used in the cross validation framework instead of the default predict By Ori Ziv and Sears
Merritt
• The training scores and time taken for training followed by scoring for each search candidate are now available
at thecvresults dict See Model Selection Enhancements and API Changes for more information 7325
by Eugene Chen and Raghav RV
Metrics
• Addedlabels flag tometricslogloss to explicitly provide the labels when the number of classes in
ytrue andypred differ 7239 by Hong Guangguo with help from Mads Jensen and Nelson Liu
• Support sparse contingency matrices in cluster evaluation metricsclustersupervised to scale to a
large number of clusters 7419 by Gregory Stupp and Joel Nothman
• Addsampleweight parameter to metricsmatthewscorrcoef By Jatin Shah and Raghav RV
• Speed up metricssilhouettescore by using vectorized operations By Manoj Kumar
• Addsampleweight parameter to metricsconfusionmatrix By Bernardo Stein
Miscellaneous
• Addednjobs parameter to featureselectionRFECV to compute the score on the test folds in par
allel By Manoj Kumar
• Codebase does not contain CC cython generated files they are generated during build Distribution packages
will still contain generated CC files By Arthur Mensch
• Reduce the memory usage for 32bit float input arrays of utilssparsefuncmeanvarianceaxis
andutilssparsefuncincrmeanvarianceaxis by supporting cython fused types By
YenChen Lin
• Theignorewarnings now accept a category argument to ignore only the warnings of a specified type By
Thierry Guillemot
• Added parameter returnXy and return type data target tuple option toloadiris
dataset 7049 loadbreastcancer dataset 7152 loaddigits datasetloaddiabetes dataset
loadlinnerud datasetloadboston dataset 7154 by Manvendra Singh
• Simplification of the clone function deprecate support for estimators that modify parameters in init
5540 by Andreas Müller
• When unpickling a scikitlearn estimator in a different version than the one the estimator was trained with a
UserWarning is raised see the documentation on model persistence for more details 7248 By Andreas
Müller

scikitlearn user guide Release 0213
Bug fixes
Trees and ensembles
• Random forest extra trees decision trees and gradient boosting won’t accept anymore minsamplessplit1 as at least 2 samples are required to split a decision tree node By Arnaud Joly
•ensembleVotingClassifier now raises NotFittedError ifpredict transform or predictproba are called on the nonfitted estimator by Sebastian Raschka
• Fix bug where ensembleAdaBoostClassifier andensembleAdaBoostRegressor would per form poorly if the randomstate was fixed 7411 By Joel Nothman
• Fix bug in ensembles with randomization where the ensemble would not set randomstate on base estimators in a pipeline or similar nesting 7411 Note results for ensemble BaggingClassifier ensembleBaggingRegressor ensembleAdaBoostClassifier and ensembleAdaBoostRegressor will now differ from previous versions By Joel Nothman
Linear kernelized and related models
• Fixed incorrect gradient computation for losssquaredepsiloninsensitive in linearmodelSGDClassifier andlinearmodelSGDRegressor 6764 By Wenhua Yang
• Fix bug in linearmodelLogisticRegressionCV wheresolverliblinear did not accept classweightsbalanced 6817 By Tom Dupre la Tour
• Fix bug in neighborsRadiusNeighborsClassifier where an error occurred when there were out liers being labelled and a weight function specified 6902 By LeonieBorne
• FixlinearmodelElasticNet sparse decision function to match output with dense in the multioutput case
Decomposition manifold learning and clustering
•decompositionRandomizedPCA default number of iteratedpower is 4 instead of 3 5141 by Giorgio Patrini
•utilsextmathrandomizedsvd performs 4 power iterations by default instead or 0 In practice this is enough for obtaining a good approximation of the true eigenvaluesvectors in the presence of noise When ncomponents is small 1minXshape niter is set to 7 unless the user specifies a higher number This improves precision with few components 5299 by Giorgio Patrini
• Whitennonwhiten inconsistency between components of decompositionPCA anddecomposition RandomizedPCA now factored into PCA see the New features is fixed components are stored with no whitening 5299 by Giorgio Patrini
• Fixed bug in manifoldspectralembedding where diagonal of unnormalized Laplacian matrix was incorrectly set to 1 4995 by Peter Fischer
• Fixed incorrect initialization of utilsarpackeigsh on all occurrences Affects cluster biclusterSpectralBiclustering decompositionKernelPCA manifold LocallyLinearEmbedding andmanifoldSpectralEmbedding 5012 By Peter Fischer
• Attribute explainedvarianceratio calculated with the SVD solver of discriminantanalysisLinearDiscriminantAnalysis now returns correct results By JPFrancoia
Preprocessing and feature selection
•preprocessingdatatransformselected now always passes a copy of Xto transform function whencopyTrue 7194 By Caio Oliveira

Model evaluation and metaestimators
•modelselectionStratifiedKFold now raises error if all nlabels for individual classes is less than nfolds 6182 by Devashish Deshpande
• Fixed bug in modelselectionStratifiedShuffleSplit where train and test sample could overlap in some edge cases see 6121 for more details By Loic Esteve
• Fix in sklearnmodelselectionStratifiedShuffleSplit to return splits of size trainsize andtestsize in all cases 6472 By Andreas Müller
• Crossvalidation of OneVsOneClassifier andOneVsRestClassifier now works with precomputed kernels 7350 by Russell Smith
• Fix incomplete predictproba method delegation from modelselectionGridSearchCV to linearmodelSGDClassifier 7159 by Yichuan Liu
Metrics
• Fix bug in metricssilhouettescore in which clusters of size 1 were incorrectly scored They should get a score of 0 By Joel Nothman
• Fix bug in metricssilhouettesamples so that it now works with arbitrary labels not just those ranging from 0 to nclusters 1
• Fix bug where expected and adjusted mutual information were incorrect if cluster contingency cells exceeded 216 By Joel Nothman
•metricspairwisepairwisedistances now converts arrays to boolean arrays when required in scipyspatialdistance 5460 by Tom Dupre la Tour
• Fix sparse input support in metricssilhouettescore as well as example exam plestextdocumentclusteringpy By YenChen Lin
•metricsroccurve andmetricsprecisionrecallcurve no longer round yscore values when creating ROC curves this was causing problems for users with very small differences in scores 7353
Miscellaneous
•modelselectiontestssearchcheckparamgrid now works correctly with all types that extendsimplements Sequence except string including range Python 3x and xrange Python 2x 7323 by Viacheslav Kovalevskyi
•utilsextmathrandomizedrangefinder is more numerically stable when many power iterations are requested since it applies LU normalization by default If niter2 numerical issues are unlikely thus no normalization is applied Other normalization options are available none LU andQR 5141 by Giorgio Patrini
• Fix a bug where some formats of scipysparse matrix and estimators with them as parameters could not be passed to baseclone By Loic Esteve
•datasetsloadsvmlightfile now is able to read long int QID values 7101 by Ibraim Ganiev
API changes summary
Linear kernelized and related models
•residualmetric has been deprecated in linearmodelRANSACRegressor Useloss instead By Manoj Kumar
• Access to public attributes X andy has been deprecated in isotonicIsotonicRegression By Jonathan Arfa

Decomposition manifold learning and clustering
• The oldmixtureDPGMM is deprecated in favor of the new mixtureBayesianGaussianMixture with the parameter weightconcentrationpriortypedirichletprocess The new class solves the computational problems of the old class and computes the Gaussian mixture with a Dirich let process prior faster than before 7295 by Wei Xue and Thierry Guillemot
• The oldmixtureVBGMM is deprecated in favor of the new mixtureBayesianGaussianMixture with the parameter weightconcentrationpriortypedirichletdistribution The new class solves the computational problems of the old class and computes the Variational Bayesian Gaussian mixture faster than before 6651 by Wei Xue and Thierry Guillemot
• The oldmixtureGMM is deprecated in favor of the new mixtureGaussianMixture The new class computes the Gaussian mixture faster than before and some of computational problems have been solved 6666 by Wei Xue and Thierry Guillemot
Model evaluation and metaestimators
• Thesklearncrossvalidation sklearngridsearch andsklearnlearningcurve have been deprecated and the classes and functions have been reorganized into the sklearn modelselection module Ref Model Selection Enhancements and API Changes for more information 4294 by Raghav RV
• Thegridscores attribute of modelselectionGridSearchCV andmodelselection RandomizedSearchCV is deprecated in favor of the attribute cvresults Ref Model Selection En hancements and API Changes for more information 6697 by Raghav RV
• The parameters niter ornfolds in old CV splitters are replaced by the new parameter nsplits since it can provide a consistent and unambiguous interface to represent the number of traintest splits 7187 by YenChen Lin
•classes parameter was renamed to labels inmetricshammingloss 7260 by Sebastián Vanrell
• The splitter classes LabelKFold LabelShuffleSplit LeaveOneLabelOut and LeavePLabelsOut are renamed to modelselectionGroupKFold modelselection GroupShuffleSplit modelselectionLeaveOneGroupOut andmodelselection LeavePGroupsOut respectively Also the parameter labels in thesplit method of the newly renamed splittersmodelselectionLeaveOneGroupOut andmodelselectionLeavePGroupsOut is renamed to groups Additionally in modelselectionLeavePGroupsOut the parameter nlabels is renamed to ngroups 6660 by Raghav RV
• Error and loss names for scoring parameters are now prefixed by neg such as negmeansquarederror The unprefixed versions are deprecated and will be removed in version 020 7261 by Tim Head

1177 Version 0171
February 18 2016
Changelog
Bug fixes
• Upgrade vendored joblib to version 094 that fixes an important bug in joblibParallel that can silently yield to wrong results when working on datasets larger than 1MB httpsgithubcomjoblibjoblibblob094 CHANGESrst
• Fixed reading of Bunch pickles generated with scikitlearn version 016 This can affect users who have already downloaded a dataset with scikitlearn 016 and are loading it with scikitlearn 017 See 6196 for how this affected datasetsfetch20newsgroups By Loic Esteve
• Fixed a bug that prevented using ROC AUC score to perform grid search on several CPU cores on large arrays See 6147 By Olivier Grisel
• Fixed a bug that prevented to properly set the presort parameter in ensemble GradientBoostingRegressor See 5857 By Andrew McCulloh
• Fixed a joblib error when evaluating the perplexity of a decomposition LatentDirichletAllocation model See 6258 By ChyiKwei Yau

scikitlearn user guide Release 0213
1178 Version 017
November 5 2015
Changelog
New features
• All the Scaler classes but preprocessingRobustScaler can be fitted online by calling partialfit By Giorgio Patrini
• The new class ensembleVotingClassifier implements a “majority rule” “soft voting” ensemble classifier to combine estimators for classification By Sebastian Raschka
• The new class preprocessingRobustScaler provides an alternative to preprocessing StandardScaler for featurewise centering and range normalization that is robust to outliers By Thomas Unterthiner
• The new class preprocessingMaxAbsScaler provides an alternative to preprocessing MinMaxScaler for featurewise range normalization when the data is already centered or sparse By Thomas Unterthiner
• The new class preprocessingFunctionTransformer turns a Python function into a Pipeline compatible transformer object By Joe Jevnik
• The new classes crossvalidationLabelKFold andcrossvalidation LabelShuffleSplit generate traintest folds respectively similar to crossvalidationKFold and crossvalidationShuffleSplit except that the folds are conditioned on a label array By Brian McFee Jean Kossaifi and Gilles Louppe
•decompositionLatentDirichletAllocation implements the Latent Dirichlet Allocation topic model with online variational inference By ChyiKwei Yau with code based on an implementation by Matt Hoffman 3659
• The new solver sag implements a Stochastic Average Gradient descent and is available in both linearmodelLogisticRegression andlinearmodelRidge This solver is very efficient for large datasets By Danny Sullivan and Tom Dupre la Tour 4738
• The new solver cdimplements a Coordinate Descent in decompositionNMF Previous solver based on Projected Gradient is still available setting new parameter solver topg but is deprecated and will be removed in 019 along with decompositionProjectedGradientNMF and parameters sparseness eta beta andnlsmaxiter New parameters alpha andl1ratio control L1 and L2 regularization and shuffle adds a shuffling step in the cdsolver By Tom Dupre la Tour and Mathieu Blondel
Enhancements
•manifoldTSNE now supports approximate optimization via the BarnesHut method leading to much faster fitting By Christopher Erick Moody 4025
•clustermeanshiftMeanShift now supports parallel execution as implemented in the meanshift function By Martino Sorbaro
•naivebayesGaussianNB now supports fitting with sampleweight By Jan Hendrik Metzen
•dummyDummyClassifier now supports a prior fitting strategy By Arnaud Joly
• Added afitpredict method for mixtureGMM and subclasses By Cory Lorenz

scikitlearn user guide Release 0213
• Added the metricslabelrankingloss metric By Arnaud Joly
• Added the metricscohenkappascore metric
• Added a warmstart constructor parameter to the bagging ensemble models to increase the size of the en
semble By Tim Head
• Added option to use multioutput regression metrics without averaging By Konstantin Shmelkov and Michael
Eickenberg
• Addedstratify option tocrossvalidationtraintestsplit for stratified splitting By
Miroslav Batchkarov
• Thetreeexportgraphviz function now supports aesthetic improvements for tree
DecisionTreeClassifier andtreeDecisionTreeRegressor including options for coloring
nodes by their majority class or impurity showing variable names and using node proportions instead of raw
sample counts By Trevor Stephens
• Improved speed of newtoncg solver inlinearmodelLogisticRegression by avoiding loss com
putation By Mathieu Blondel and Tom Dupre la Tour
• Theclassweightauto heuristic in classifiers supporting classweight was deprecated and re
placed by the classweightbalanced option which has a simpler formula and interpretation By
Hanna Wallach and Andreas Müller
• Addclassweight parameter to automatically weight samples by class frequency for linearmodel
PassiveAggressiveClassifier By Trevor Stephens
• Added backlinks from the API reference pages to the user guide By Andreas Müller
• Thelabels parameter to sklearnmetricsf1score sklearnmetricsfbetascore
sklearnmetricsrecallscore andsklearnmetricsprecisionscore has been ex
tended It is now possible to ignore one or more labels such as where a multiclass problem has a majority
class to ignore By Joel Nothman
• Addsampleweight support tolinearmodelRidgeClassifier By Trevor Stephens
• Provide an option for sparse output from sklearnmetricspairwisecosinesimilarity By
Jaidev Deshpande
• Addminmaxscale to provide a function interface for MinMaxScaler By Thomas Unterthiner
•dumpsvmlightfile now handles multilabel datasets By ChihWei Chang
• RCV1 dataset loader sklearndatasetsfetchrcv1 By Tom Dupre la Tour
• The “Wisconsin Breast Cancer” classical twoclass classification dataset is now included in scikitlearn avail
able withsklearndatasetloadbreastcancer
• Upgraded to joblib 093 to benefit from the new automatic batching of short tasks This makes it possible for
scikitlearn to benefit from parallelism when many very short tasks are executed in parallel for instance by the
gridsearchGridSearchCV metaestimator with njobs 1 used with a large grid of parameters on
a small dataset By Vlad Niculae Olivier Grisel and Loic Esteve
• For more details about changes in joblib 093 see the release notes httpsgithubcomjoblibjoblibblobmaster
CHANGESrstrelease093
• Improved speed 3 times per iteration of decompositionDictLearning with coordinate descent
method from linearmodelLasso By Arthur Mensch
• Parallel processing threaded for queries of nearest neighbors using the balltree by Nikolay Mayorov
• Allowdatasetsmakemultilabelclassification to output a sparse y By Kashif Rasul

•clusterDBSCAN now accepts a sparse matrix of precomputed distances allowing memoryefficient distance precomputation By Joel Nothman
•treeDecisionTreeClassifier now exposes an apply method for retrieving the leaf indices samples are predicted as By Daniel Galvez and Gilles Louppe
• Speed up decision tree regressors random forest regressors extra trees regressors and gradient boosting estimators by computing a proxy of the impurity improvement during the tree growth The proxy quantity is such that the split that maximizes this value also maximizes the impurity improvement By Arnaud Joly Jacob Schreiber and Gilles Louppe
• Speed up tree based methods by reducing the number of computations needed when computing the impurity measure taking into account linear relationship of the computed statistics The effect is particularly visible with extra trees and on datasets with categorical or sparse features By Arnaud Joly
•ensembleGradientBoostingRegressor andensembleGradientBoostingClassifier now expose an apply method for retrieving the leaf indices each sample ends up in under each try By Jacob Schreiber
• Addsampleweight support tolinearmodelLinearRegression By Sonny Hu 4881
• Addniterwithoutprogress tomanifoldTSNE to control the stopping criterion By Santi Villalba 5186
• Added optional parameter randomstate inlinearmodelRidge to set the seed of the pseudo random generator used in sag solver By Tom Dupre la Tour
• Added optional parameter warmstart inlinearmodelLogisticRegression If set to True the solverslbfgs newtoncg andsag will be initialized with the coefficients computed in the previous fit By Tom Dupre la Tour
• Addedsampleweight support to linearmodelLogisticRegression for thelbfgs newtoncg andsag solvers By Valentin Stolbunov Support added to the liblinear solver By Manoj Kumar
• Added optional parameter presort toensembleGradientBoostingRegressor andensemble GradientBoostingClassifier keeping default behavior the same This allows gradient boosters to turn off presorting when building deep trees or using sparse data By Jacob Schreiber
• Alteredmetricsroccurve to drop unnecessary thresholds by default By Graham Clenaghan
• AddedfeatureselectionSelectFromModel metatransformer which can be used along with estimators that have coef orfeatureimportances attribute to select important features of the input data By Maheshakya Wijewardena Joel Nothman and Manoj Kumar
• Addedmetricspairwiselaplaciankernel By Clyde Fare
•covarianceGraphLasso allows separate control of the convergence criterion for the ElasticNet subproblem via the enettol parameter
• Improved verbosity in decompositionDictionaryLearning
•ensembleRandomForestClassifier andensembleRandomForestRegressor no longer explicitly store the samples used in bagging resulting in a much reduced memory footprint for storing random forest models
• Addedpositive option tolinearmodelLars andlinearmodellarspath to force coefficients to be positive 5131
• Added the Xnormsquared parameter to metricspairwiseeuclideandistances to provide precomputed squared norms for X
• Added the fitpredict method topipelinePipeline

• Added the preprocessingminmaxscale function

Bug fixes

• Fixed nondeterminism in dummyDummyClassifier with sparse multilabel output By Andreas Müller
• Fixed the output shape of linearmodelRANSACRegressor tonsamples By Andreas Müller
• Fixed bug in decompositionDictLearning whennjobs 0 By Andreas Müller
• Fixed bug where gridsearchRandomizedSearchCV could consume a lot of memory for large discrete grids By Joel Nothman
• Fixed bug in linearmodelLogisticRegressionCV wherepenalty was ignored in the final fit By Manoj Kumar
• Fixed bug in ensembleforestForestClassifier while computing oobscore and X is a sparsecscmatrix By Ankur Ankan
• All regressors now consistently handle and warn when given ythat is of shape nsamples 1 By Andreas Müller and Henry Lin 5431
• Fix inclusterKMeans cluster reassignment for sparse input by Lars Buitinck
• Fixed a bug in ldaLDA that could cause asymmetric covariance matrices when using shrinkage By Martin Billinger
• Fixedcrossvalidationcrossvalpredict for estimators with sparse predictions By Buddha Prakash
• Fixed the predictproba method oflinearmodelLogisticRegression to use softmax instead of onevsrest normalization By Manoj Kumar 5182
• Fixed the partialfit method of linearmodelSGDClassifier when called with averageTrue By Andrew Lamb 5282
• Dataset fetchers use different filenames under Python 2 and Python 3 to avoid pickling compatibility issues By Olivier Grisel 5355
• Fixed a bug in naivebayesGaussianNB which caused classification results to depend on scale By Jake Vanderplas
• Fixed temporarily linearmodelRidge which was incorrect when fitting the intercept in the case of sparse data The fix automatically changes the solver to ‘sag’ in this case 5360 by Tom Dupre la Tour
• Fixed a performance bug in decompositionRandomizedPCA on data with a large number of features and fewer samples 4478 By Andreas Müller Loic Esteve and Giorgio Patrini
• Fixed bug in crossdecompositionPLS that yielded unstable and platform dependent output and failed onfittransform By Arthur Mensch
• Fixes to the Bunch class used to store datasets
• Fixedensembleplotpartialdependence ignoring the percentiles parameter
• Providing a set as vocabulary in CountVectorizer no longer leads to inconsistent results when pickling
• Fixed the conditions on when a precomputed Gram matrix needs to be recomputed in linearmodel LinearRegression linearmodelOrthogonalMatchingPursuit linearmodelLasso andlinearmodelElasticNet
• Fixed inconsistent memory layout in the coordinate descent solver that affected linearmodel DictionaryLearning andcovarianceGraphLasso 5337 By Olivier Grisel

•manifoldLocallyLinearEmbedding no longer ignores the reg parameter
• Nearest Neighbor estimators with custom distance metrics can now be pickled 4362
• Fixed a bug in pipelineFeatureUnion wheretransformerweights were not properly handled
when performing gridsearches
• Fixed a bug in linearmodelLogisticRegression andlinearmodel
LogisticRegressionCV when using classweightbalanced orclassweightauto
By Tom Dupre la Tour
• Fixed bug 5495 when doing OVRSVCdecisionfunctionshape”ovr” Fixed by Elvis Dohmatob
API changes summary
• Attribute datamin datamax anddatarange inpreprocessingMinMaxScaler are depre
cated and won’t be available from 019 Instead the class now exposes datamin datamax and
datarange By Giorgio Patrini
• All Scaler classes now have an scale attribute the featurewise rescaling applied by their transform methods
The old attribute std inpreprocessingStandardScaler is deprecated and superseded by scale
it won’t be available in 019 By Giorgio Patrini
•svmSVC andsvmNuSVC now have an decisionfunctionshape parameter to make their decision
function of shape nsamples nclasses by settingdecisionfunctionshapeovr This
will be the default behavior starting in 019 By Andreas Müller
• Passing 1D data arrays as input to estimators is now deprecated as it caused confusion in how the array ele
ments should be interpreted as features or as samples All data arrays are now expected to be explicitly shaped
nsamples nfeatures By Vighnesh Birodkar
•ldaLDA andqdaQDA have been moved to discriminantanalysis
LinearDiscriminantAnalysis and discriminantanalysis
QuadraticDiscriminantAnalysis
• Thestorecovariance andtol parameters have been moved from the fit method to the constructor in
discriminantanalysisLinearDiscriminantAnalysis and thestorecovariances and
tol parameters have been moved from the fit method to the constructor in discriminantanalysis
QuadraticDiscriminantAnalysis
• Models inheriting from LearntSelectorMixin will no longer support the transform methods ie Ran
domForests GradientBoosting LogisticRegression DecisionTrees SVMs and SGD related models Wrap
these models around the metatransfomer featureselectionSelectFromModel to remove features
according to coefs orfeatureimportances which are below a certain threshold value instead
•clusterKMeans reruns clusterassignments in case of nonconvergence to ensure consistency of
predictX andlabels By Vighnesh Birodkar
• Classifier and Regressor models are now tagged as such using the estimatortype attribute
• Crossvalidation iterators always provide indices into training and test set not boolean masks
• Thedecisionfunction on all regressors was deprecated and will be removed in 019 Use predict
instead
•datasetsloadlfwpairs is deprecated and will be removed in 019 Use datasets
fetchlfwpairs instead
• The deprecated hmm module was removed
• The deprecated Bootstrap crossvalidation iterator was removed

scikitlearn user guide Release 0213
• The deprecated Ward andWardAgglomerative classes have been removed Use clustering
AgglomerativeClustering instead
•crossvalidationcheckcv is now a public function
• The property residues oflinearmodelLinearRegression is deprecated and will be removed in
019
• The deprecated njobs parameter of linearmodelLinearRegression has been moved to the con
structor
• Removed deprecated classweight parameter from linearmodelSGDClassifier ’sfit method
Use the construction parameter instead
• The deprecated support for the sequence of sequences or list of lists multilabel format was removed To convert
to and from the supported binary indicator matrix format use MultiLabelBinarizer
• The behavior of calling the inversetransform method ofPipelinepipeline will change in 019
It will no longer reshape onedimensional input to twodimensional input
• The deprecated attributes indicatormatrix multilabel andclasses ofpreprocessing
LabelBinarizer were removed
• Usinggamma0 insvmSVC andsvmSVR to automatically set the gamma to 1 nfeatures is dep
recated and will be removed in 019 Use gammaauto instead

1179 Version 0161
April 14 2015
117 Previous Releases 93

scikitlearn user guide Release 0213
Changelog
Bug fixes
• Allow input data larger than blocksize incovarianceLedoitWolf by Andreas Müller
• Fix a bug in isotonicIsotonicRegression deduplication that caused unstable result in calibrationCalibratedClassifierCV by Jan Hendrik Metzen
• Fix sorting of labels in func preprocessinglabelbinarize by Michael Heilman
• Fix several stability and convergence issues in crossdecompositionCCA and crossdecompositionPLSCanonical by Andreas Müller
• Fix a bug in clusterKMeans whenprecomputedistancesFalse on fortranordered data
• Fix a speed regression in ensembleRandomForestClassifier ’spredict andpredictproba by Andreas Müller
• Fix a regression where utilsshuffle converted lists and dataframes to arrays by Olivier Grisel
11710 Version 016
March 26 2015
Highlights
• Speed improvements notably in clusterDBSCAN reduced memory requirements bugfixes and better default settings
• Multinomial Logistic regression and a path algorithm in linearmodelLogisticRegressionCV
• Outof core learning of PCA via decompositionIncrementalPCA
• Probability callibration of classifiers using calibrationCalibratedClassifierCV
•clusterBirch clustering method for largescale datasets
• Scalable approximate nearest neighbors search with Localitysensitive hashing forests in neighbors LSHForest
• Improved error messages and better validation when using malformed input data
• More robust integration with pandas dataframes
Changelog
New features
• The new neighborsLSHForest implements localitysensitive hashing for approximate nearest neighbors search By Maheshakya Wijewardena
• AddedsvmLinearSVR This class uses the liblinear implementation of Support Vector Regression which is much faster for large sample sizes than svmSVR with linear kernel By Fabian Pedregosa and Qiang Luo
• Incremental fit for GaussianNB
• Addedsampleweight support todummyDummyClassifier anddummyDummyRegressor By Arnaud Joly

• Added the metricslabelrankingaverageprecisionscore metrics By Arnaud Joly
• Add themetricscoverageerror metrics By Arnaud Joly
• AddedlinearmodelLogisticRegressionCV By Manoj Kumar Fabian Pedregosa Gael Varoquaux
and Alexandre Gramfort
• Addedwarmstart constructor parameter to make it possible for any trained forest model to grow additional
trees incrementally By Laurent Direr
• Addedsampleweight support to ensembleGradientBoostingClassifier andensemble
GradientBoostingRegressor By Peter Prettenhofer
• AddeddecompositionIncrementalPCA an implementation of the PCA algorithm that supports out
ofcore learning with a partialfit method By Kyle Kastner
• Averaged SGD for SGDClassifier andSGDRegressor By Danny Sullivan
• Addedcrossvalpredict function which computes crossvalidated estimates By Luis Pedro Coelho
• AddedlinearmodelTheilSenRegressor a robust generalizedmedianbased estimator By Florian
Wilhelm
• Addedmetricsmedianabsoluteerror a robust metric By Gael Varoquaux and Florian Wilhelm
• AddclusterBirch an online clustering algorithm By Manoj Kumar Alexandre Gramfort and Joel Noth
man
• Added shrinkage support to discriminantanalysisLinearDiscriminantAnalysis using two
new solvers By Clemens Brunner and Martin Billinger
• AddedkernelridgeKernelRidge an implementation of kernelized ridge regression By Mathieu
Blondel and Jan Hendrik Metzen
• All solvers in linearmodelRidge now support sampleweight By Mathieu Blondel
• AddedcrossvalidationPredefinedSplit crossvalidation for fixed userprovided crossvalidation
folds By Thomas Unterthiner
• AddedcalibrationCalibratedClassifierCV an approach for calibrating the predicted probabili
ties of a classifier By Alexandre Gramfort Jan Hendrik Metzen Mathieu Blondel and Balazs Kegl
Enhancements
• Add option returndistance inhierarchicalwardtree to return distances between nodes for
both structured and unstructured versions of the algorithm By Matteo Visconti di Oleggio Castello The same
option was added in hierarchicallinkagetree By Manoj Kumar
• Add support for sample weights in scorer objects Metrics with sample weight support will automatically benefit
from it By Noel Dawe and Vlad Niculae
• Addednewtoncg andlbfgs solver support in linearmodelLogisticRegression By Manoj
Kumar
• Addselectionrandom parameter to implement stochastic coordinate descent for linearmodel
Lasso linearmodelElasticNet and related By Manoj Kumar
• Addsampleweight parameter to metricsjaccardsimilarityscore andmetrics
logloss By Jatin Shah
• Support sparse multilabel indicator representation in preprocessingLabelBinarizer and
multiclassOneVsRestClassifier by Hamzeh Alsalhi with thanks to Rohit Sivaprasad as
well as evaluation metrics by Joel Nothman

• Addsampleweight parameter to metricsjaccardsimilarityscore ByJatin Shah
• Add support for multiclass in metricshingeloss AddedlabelsNone as optional parameter By Saurabh Jha
• Addsampleweight parameter to metricshingeloss BySaurabh Jha
• Addmulticlassmultinomial option inlinearmodelLogisticRegression to implement a Logistic Regression solver that minimizes the crossentropy or multinomial loss instead of the default OnevsRest setting Supports lbfgs andnewtoncg solvers By Lars Buitinck and Manoj Kumar Solver optionnewtoncg by Simon Wu
•DictVectorizer can now perform fittransform on an iterable in a single pass when giving the option sortFalse By Dan Blanchard
•GridSearchCV andRandomizedSearchCV can now be configured to work with estimators that may fail and raise errors on individual folds This option is controlled by the errorscore parameter This does not affect errors raised on refit By Michal Romaniuk
• Adddigits parameter to metricsclassificationreport to allow report to show different precision of floating point numbers By Ian Gilmore
• Add a quantile prediction strategy to the dummyDummyRegressor By Aaron Staple
• Addhandleunknown option topreprocessingOneHotEncoder to handle unknown categorical features more gracefully during transform By Manoj Kumar
• Added support for sparse input data to decision trees and their ensembles By Fares Hedyati and Arnaud Joly
• Optimized clusterAffinityPropagation by reducing the number of memory allocations of large temporary datastructures By Antony Lee
• Parellization of the computation of feature importances in random forest By Olivier Grisel and Arnaud Joly
• Addniter attribute to estimators that accept a maxiter attribute in their constructor By Manoj Kumar
• Added decision function for multiclassOneVsOneClassifier By Raghav RV and Kyle Beauchamp
•neighborskneighborsgraph andradiusneighborsgraph support nonEuclidean metrics By Manoj Kumar
• Parameter connectivity inclusterAgglomerativeClustering and family now accept callables that return a connectivity matrix By Manoj Kumar
• Sparse support for paireddistances By Joel Nothman
•clusterDBSCAN now supports sparse input and sample weights and has been optimized the inner loop has been rewritten in Cython and radius neighbors queries are now computed in batch By Joel Nothman and Lars Buitinck
• Addclassweight parameter to automatically weight samples by class frequency for ensembleRandomForestClassifier treeDecisionTreeClassifier ensemble ExtraTreesClassifier andtreeExtraTreeClassifier By Trevor Stephens
•gridsearchRandomizedSearchCV now does sampling without replacement if all parameters are given as lists By Andreas Müller
• Parallelized calculation of pairwisedistances is now supported for scipy metrics and custom callables By Joel Nothman
• Allow the fitting and scoring of all clustering algorithms in pipelinePipeline By Andreas Müller
• More robust seeding and improved error messages in clusterMeanShift by Andreas Müller

• Make the stopping criterion for mixtureGMM mixtureDPGMM andmixtureVBGMM less dependent on the number of samples by thresholding the average loglikelihood change instead of its sum over all samples By Hervé Bredin
• The outcome of manifoldspectralembedding was made deterministic by flipping the sign of eigen vectors By Hasil Sharma
• Significant performance and memory usage improvements in preprocessingPolynomialFeatures By Eric Martin
• Numerical stability improvements for preprocessingStandardScaler andpreprocessing scale By Nicolas Goix
•svmSVC fitted on sparse input now implements decisionfunction By Rob Zinkov and Andreas Müller
•crossvalidationtraintestsplit now preserves the input type instead of converting to numpy arrays
Documentation improvements
• Added example of using FeatureUnion for heterogeneous input By Matt Terry
• Documentation on scorers was improved to highlight the handling of loss functions By Matt Pico
• A discrepancy between liblinear output and scikitlearn's wrappers is now noted By Manoj Kumar
• Improved documentation generation examples referring to a class or function are now shown in a gallery on the classfunction's API reference page By Joel Nothman
• More explicit documentation of sample generators and of data transformation By Joel Nothman
•sklearnneighborsBallTree andsklearnneighborsKDTree used to point to empty pages stating that they are aliases of BinaryTree This has been fixed to show the correct class docs By Manoj Kumar
• Added silhouette plots for analysis of KMeans clustering using metricssilhouettesamples and metricssilhouettescore See Selecting the number of clusters with silhouette analysis on KMeans clustering
Bug fixes
• Metaestimators now support ducktyping for the presence of decisionfunction predictproba and other methods This fixes behavior of gridsearchGridSearchCV gridsearchRandomizedSearchCV pipelinePipeline featureselectionRFE featureselectionRFECV when nested By Joel Nothman
• Thescoring attribute of gridsearch and crossvalidation methods is no longer ignored when a gridsearchGridSearchCV is given as a base estimator or the base estimator doesn't have predict
• The function hierarchicalwardtree now returns the children in the same order for both the structured and unstructured versions By Matteo Visconti di Oleggio Castello
•featureselectionRFECV now correctly handles cases when step is not equal to 1 By Nikolay Mayorov
• ThedecompositionPCA now undoes whitening in its inversetransform Also itscomponents now always have unit length By Michael Eickenberg
• Fix incomplete download of the dataset when datasetsdownload20newsgroups is called By Manoj Kumar

• Various fixes to the Gaussian processes subpackage by Vincent Dubourg and Jan Hendrik Metzen
• Callingpartialfit withclassweightauto throws an appropriate error message and suggests
a work around By Danny Sullivan
•RBFSampler withgammag formerly approximated rbfkernel withgammag2 the definition of
gamma is now consistent which may substantially change your results if you use a fixed value If you cross
validated over gamma it probably doesn't matter too much By Dougal Sutherland
• Pipeline object delegate the classes attribute to the underlying estimator It allows for instance to make
bagging of a pipeline object By Arnaud Joly
•neighborsNearestCentroid now uses the median as the centroid when metric is set to manhattan
It was using the mean before By Manoj Kumar
• Fix numerical stability issues in linearmodelSGDClassifier andlinearmodel
SGDRegressor by clipping large gradients and ensuring that weight decay rescaling is always positive for
large l2 regularization and large learning rate values By Olivier Grisel
• Whencomputefulltree is set to "auto" the full tree is built when nclusters is high and
is early stopped when nclusters is low while the behavior should be viceversa in cluster
AgglomerativeClustering and friends This has been fixed By Manoj Kumar
• Fix lazy centering of data in linearmodelenetpath andlinearmodellassopath It was
centered around one It has been changed to be centered around the origin By Manoj Kumar
• Fix handling of precomputed affinity matrices in clusterAgglomerativeClustering when using
connectivity constraints By Cathy Deng
• Correctpartialfit handling of classprior forsklearnnaivebayesMultinomialNB and
sklearnnaivebayesBernoulliNB By Trevor Stephens
• Fixed a crash in metricsprecisionrecallfscoresupport when using unsorted labels in the
multilabel setting By Andreas Müller
• Avoid skipping the first nearest neighbor in the methods radiusneighbors kneighbors
kneighborsgraph andradiusneighborsgraph insklearnneighbors
NearestNeighbors and family when the query data is not the same as fit data By Manoj Kumar
• Fix logdensity calculation in the mixtureGMM with tied covariance By Will Dawson
• Fixed a scaling error in featureselectionSelectFdr where a factor nfeatures was missing By
Andrew Tulloch
• Fix zero division in neighborsKNeighborsRegressor and related classes when using distance weight
ing and having identical data points By GarretR
• Fixed round off errors with non positivedefinite covariance matrices in GMM By Alexis Mignon
• Fixed a error in the computation of conditional probabilities in naivebayesBernoulliNB By Hanna
Wallach
• Make the method radiusneighbors ofneighborsNearestNeighbors return the samples lying
on the boundary for algorithmbrute By Yan Yi
• Flip sign of dualcoef ofsvmSVC to make it consistent with the documentation and
decisionfunction By Artem Sobolev
• Fixed handling of ties in isotonicIsotonicRegression We now use the weighted average of targets
secondary method By Andreas Müller and Michael Bommarito

API changes summary
•GridSearchCV andcrossvalscore and other metaestimators don’t convert pandas DataFrames into arrays any more allowing DataFrame specific operations in custom estimators
•multiclassfitovr multiclasspredictovr predictprobaovr multiclass fitovo multiclasspredictovo multiclassfitecoc andmulticlass predictecoc are deprecated Use the underlying estimators instead
• Nearest neighbors estimators used to take arbitrary keyword arguments and pass these to their distance metric This will no longer be supported in scikitlearn 018 use the metricparams argument instead
•njobs parameter of the fit method shifted to the constructor of the LinearRegression class
• Thepredictproba method ofmulticlassOneVsRestClassifier now returns two probabilities per sample in the multiclass case this is consistent with other estimators and with the method’s documenta tion but previous versions accidentally returned only the positive probability Fixed by Will Lamond and Lars Buitinck
• Change default value of precompute in ElasticNet andLasso to False Setting precompute to “auto” was found to be slower when nsamples nfeatures since the computation of the Gram matrix is computationally expensive and outweighs the benefit of fitting the Gram for just one alpha precomputeauto is now deprecated and will be removed in 018 By Manoj Kumar
• Exposepositive option inlinearmodelenetpath andlinearmodelenetpath which constrains coefficients to be positive By Manoj Kumar
• Users should now supply an explicit average parameter to sklearnmetricsf1score sklearn metricsfbetascore sklearnmetricsrecallscore andsklearnmetrics precisionscore when performing multiclass or multilabel ie not binary classification By Joel Nothman
•scoring parameter for cross validation now accepts f1micro f1macro orf1weighted f1 is now for binary classification only Similar changes apply to precision andrecall By Joel Nothman
• Thefitintercept normalize andreturnmodels parameters in linearmodelenetpath andlinearmodellassopath have been removed They were deprecated since 014
• From now onwards all estimators will uniformly raise NotFittedError utilsvalidation NotFittedError when any of the predict like methods are called before the model is fit By Raghav RV
• Input data validation was refactored for more consistent input validation The checkarrays function was replaced by checkarray andcheckXy By Andreas Müller
• AllowXNone in the methods radiusneighbors kneighbors kneighborsgraph and radiusneighborsgraph insklearnneighborsNearestNeighbors and family If set to None then for every sample this avoids setting the sample itself as the first nearest neighbor By Manoj Kumar
• Add parameter includeself inneighborskneighborsgraph andneighbors radiusneighborsgraph which has to be explicitly set by the user If set to True then the sample itself is considered as the first nearest neighbor
•thresh parameter is deprecated in favor of new tol parameter in GMMDPGMM andVBGMM See Enhancements section for details By Hervé Bredin
• Estimators will treat input with dtype object as numeric when possible By Andreas Müller
• Estimators now raise ValueError consistently when fitted on empty data less than 1 sample or less than 1 feature for 2D input By Olivier Grisel

• Theshuffle option of linearmodelSGDClassifier linearmodelSGDRegressor linearmodelPerceptron linearmodelPassiveAggressiveClassifier and linearmodelPassiveAggressiveRegressor now defaults to True
•clusterDBSCAN now uses a deterministic initialization The randomstate parameter is deprecated By Erich Schubert

11711 Version 0152

September 4 2014

Bug fixes

• Fixed handling of the pparameter of the Minkowski distance that was previously ignored in nearest neighbors models By Nikolay Mayorov
• Fixed duplicated alphas in linearmodelLassoLars with early stopping on 32 bit Python By Olivier Grisel and Fabian Pedregosa
• Fixed the build under Windows when scikitlearn is built with MSVC while NumPy is built with MinGW By Olivier Grisel and Federico Vaggi
• Fixed an array index overflow bug in the coordinate descent solver By Gael Varoquaux
• Better handling of numpy 19 deprecation warnings By Gael Varoquaux
• Removed unnecessary data copy in clusterKMeans By Gael Varoquaux
• Explicitly close open files to avoid ResourceWarnings under Python 3 By Calvin Giles

• Thetransform ofdiscriminantanalysisLinearDiscriminantAnalysis now projects the input on the most discriminant directions By Martin Billinger
• Fixed potential overflow in treesaferealloc by Lars Buitinck
• Performance optimization in isotonicIsotonicRegression By Robert Bradshaw
•nose is nonlonger a runtime dependency to import sklearn only for running the tests By Joel Nothman
• Many documentation and website fixes by Joel Nothman Lars Buitinck Matt Pico and others

11712 Version 0151

August 1 2014

Bug fixes

• Madecrossvalidationcrossvalscore usecrossvalidationKFold instead of crossvalidationStratifiedKFold on multioutput classification problems By Nikolay Mayorov
• Support unseen labels preprocessingLabelBinarizer to restore the default behavior of 0141 for backward compatibility By Hamzeh Alsalhi
• Fixed the clusterKMeans stopping criterion that prevented early convergence detection By Edward Raff and Gael Varoquaux
• Fixed the behavior of multiclassOneVsOneClassifier in case of ties at the perclass vote level by computing the correct perclass sum of prediction scores By Andreas Müller
• Madecrossvalidationcrossvalscore andgridsearchGridSearchCV accept Python lists as input data This is especially useful for crossvalidation and model selection of text processing pipelines By Andreas Müller
• Fixed data input checks of most estimators to accept input data that implements the NumPy array protocol This is the case for for pandasSeries andpandasDataFrame in recent versions of pandas By Gael Varoquaux
• Fixed a regression for linearmodelSGDClassifier withclassweightauto on data with noncontiguous labels By Olivier Grisel

11713 Version 015

July 15 2014

Highlights

• Many speed and memory improvements all across the code
• Huge speed and memory improvements to random forests and extra trees that also benefit better from parallel computing
• Incremental fit to BernoulliRBM
• AddedclusterAgglomerativeClustering for hierarchical agglomerative clustering with average linkage complete linkage and ward strategies
• AddedlinearmodelRANSACRegressor for robust regression models

• Added dimensionality reduction with manifoldTSNE which can be used to visualize highdimensional data
Changelog
New features
• AddedensembleBaggingClassifier andensembleBaggingRegressor metaestimators for
ensembling any kind of base estimator See the Bagging section of the user guide for details and examples
By Gilles Louppe
• New unsupervised feature selection algorithm featureselectionVarianceThreshold by Lars
Buitinck
• AddedlinearmodelRANSACRegressor metaestimator for the robust fitting of regression models By
Johannes Schönberger
• AddedclusterAgglomerativeClustering for hierarchical agglomerative clustering with average
linkage complete linkage and ward strategies by Nelle Varoquaux and Gael Varoquaux
• Shorthand constructors pipelinemakepipeline andpipelinemakeunion were added by Lars
Buitinck
• Shuffle option for crossvalidationStratifiedKFold By Jeffrey Blackburne
• Incremental learning partialfit for Gaussian Naive Bayes by Imran Haque
• Addedpartialfit toBernoulliRBM By Danny Sullivan
• Addedlearningcurve utility to chart performance with respect to training size See Plotting Learning
Curves By Alexander Fabisch
• Add positive option in LassoCV andElasticNetCV By Brian Wignall and Alexandre Gramfort
• AddedlinearmodelMultiTaskElasticNetCV andlinearmodelMultiTaskLassoCV By
Manoj Kumar
• AddedmanifoldTSNE By Alexander Fabisch
Enhancements
• Add sparse input support to ensembleAdaBoostClassifier andensemble
AdaBoostRegressor metaestimators By Hamzeh Alsalhi
• Memory improvements of decision trees by Arnaud Joly
• Decision trees can now be built in bestfirst manner by using maxleafnodes as the stopping criteria
Refactored the tree code to use either a stack or a priority queue for tree building By Peter Prettenhofer and
Gilles Louppe
• Decision trees can now be fitted on fortran and cstyle arrays and noncontinuous arrays without the need to
make a copy If the input array has a different dtype than npfloat32 a fortran style copy will be made
since fortranstyle memory layout has speed advantages By Peter Prettenhofer and Gilles Louppe
• Speed improvement of regression trees by optimizing the the computation of the mean square error criterion
This lead to speed improvement of the tree forest and gradient boosting tree modules By Arnaud Joly
• Theimgtograph andgridtograph functions in sklearnfeatureextractionimage now
returnnpndarray instead ofnpmatrix whenreturnasnpndarray See the Notes section for
more information on compatibility

• Changed the internal storage of decision trees to use a struct array This fixed some small bugs while improving code and providing a small speed gain By Joel Nothman
• Reduce memory usage and overhead when fitting and predicting with forests of randomized trees in parallel withnjobs 1 by leveraging new threading backend of joblib 08 and releasing the GIL in the tree fitting Cython code By Olivier Grisel and Gilles Louppe
• Speed improvement of the sklearnensemblegradientboosting module By Gilles Louppe and Peter Prettenhofer
• Various enhancements to the sklearnensemblegradientboosting module awarmstart ar gument to fit additional trees a maxleafnodes argument to fit GBM style trees a monitor fit argument to inspect the estimator during training and refactoring of the verbose code By Peter Prettenhofer
• FastersklearnensembleExtraTrees by caching feature values By Arnaud Joly
• Faster depthbased tree building algorithm such as decision tree random forest extra trees or gradient tree boosting with depth based growing strategy by avoiding trying to split on found constant features in the sample subset By Arnaud Joly
• Addminweightfractionleaf prepruning parameter to treebased methods the minimum weighted fraction of the input samples required to be at a leaf node By Noel Dawe
• Addedmetricspairwisedistancesargminmin by Philippe Gervais
• Added predict method to clusterAffinityPropagation andclusterMeanShift by Mathieu Blondel
• Vector and matrix multiplications have been optimised throughout the library by Denis Engemann and Alexan dre Gramfort In particular they should take less memory with older NumPy versions prior to 172
• Precisionrecall and ROC examples now use traintestsplit and have more explanation of why these metrics are useful By Kyle Kastner
• The training algorithm for decompositionNMF is faster for sparse matrices and has much lower memory complexity meaning it will scale up gracefully to large datasets By Lars Buitinck
• Added svdmethod option with default value to “randomized” to decompositionFactorAnalysis to save memory and significantly speedup computation by Denis Engemann and Alexandre Gramfort
• Changed crossvalidationStratifiedKFold to try and preserve as much of the original ordering of samples as possible so as not to hide overfitting on datasets with a nonnegligible level of samples dependency By Daniel Nouri and Olivier Grisel
• Add multioutput support to gaussianprocessGaussianProcess by John Novak
• Support for precomputed distance matrices in nearest neighbor estimators by Robert Layton and Joel Nothman
• Norm computations optimized for NumPy 16 and later versions by Lars Buitinck In particular the kmeans algorithm no longer needs a temporary data structure the size of its input
•dummyDummyClassifier can now be used to predict a constant output value By Manoj Kumar
•dummyDummyRegressor has now a strategy parameter which allows to predict the mean the median of the training set or a constant output value By Maheshakya Wijewardena
• Multilabel classification output in multilabel indicator format is now supported by metrics rocaucscore andmetricsaverageprecisionscore by Arnaud Joly
• Significant performance improvements more than 100x speedup for large problems in isotonic IsotonicRegression by Andrew Tulloch
• Speed and memory usage improvements to the SGD algorithm for linear models it now uses threads not separate processes when njobs1 By Lars Buitinck

• Grid search and cross validation allow NaNs in the input arrays so that preprocessors such as preprocessingImputer can be trained within the cross validation loop avoiding potentially skewed results
• Ridge regression can now deal with sample weights in feature space only sample space until then By Michael Eickenberg Both solutions are provided by the Cholesky solver
• Several classification and regression metrics now support weighted samples with the new sampleweight argument metricsaccuracyscore metricszerooneloss metricsprecisionscore metricsaverageprecisionscore metrics f1score metricsfbetascore metricsrecallscore metricsrocaucscore metricsexplainedvariancescore metricsmeansquarederror metrics meanabsoluteerror metricsr2score By Noel Dawe
• Speed up of the sample generator datasetsmakemultilabelclassification By Joel Nothman

Documentation improvements

• The Working With Text Data tutorial has now been worked in to the main documentation's tutorial section Includes exercises and skeletons for tutorial presentation Original tutorial created by several authors including Olivier Grisel Lars Buitinck and many others Tutorial integration into the scikitlearn documentation by Jaques Grobler
• Added Computational Performance documentation Discussion and examples of prediction latency throughput and different factors that have influence over speed Additional tips for building faster models and choosing a relevant compromise between speed and predictive power By Eustache Diemert

Bug fixes

• Fixed bug in decompositionMiniBatchDictionaryLearning partialfit was not working properly
• Fixed bug in linearmodelstochasticgradient l1ratio was used as 10 l1ratio

• Fixed bug in multiclassOneVsOneClassifier with string labels
• Fixed a bug in LassoCV andElasticNetCV they would not precompute the Gram matrix with precomputeTrue orprecomputeauto andnsamples nfeatures By Manoj Kumar
• Fixed incorrect estimation of the degrees of freedom in featureselectionfregression when vari ates are not centered By Virgile Fritsch
• Fixed a race condition in parallel processing with predispatch all for instance in crossvalscore By Olivier Grisel
• Raise error in clusterFeatureAgglomeration andclusterWardAgglomeration when no samples are given rather than returning meaningless clustering
• Fixed bug in gradientboostingGradientBoostingRegressor withlosshuber gamma might have not been initialized
• Fixed feature importances as computed with a forest of randomized trees when fit with sampleweight None andor with bootstrapTrue By Gilles Louppe

API changes summary
•sklearnhmm is deprecated Its removal is planned for the 017 release
• Use of covarianceEllipticEnvelop has now been removed after deprecation Please use covarianceEllipticEnvelope instead
•clusterWard is deprecated Use clusterAgglomerativeClustering instead
•clusterWardClustering is deprecated Use
•clusterAgglomerativeClustering instead
•crossvalidationBootstrap is deprecated crossvalidationKFold or crossvalidationShuffleSplit are recommended instead
• Direct support for the sequence of sequences or list of lists multilabel format is deprecated To convert to and from the supported binary indicator matrix format use MultiLabelBinarizer By Joel Nothman
• Add score method to PCA following the model of probabilistic PCA and deprecate ProbabilisticPCA model whose score implementation is not correct The computation now also exploits the matrix inversion lemma for faster computation By Alexandre Gramfort
• The score method of FactorAnalysis now returns the average loglikelihood of the samples Use scoresamples to get loglikelihood of each sample By Alexandre Gramfort
• Generating boolean masks the setting indicesFalse from crossvalidation generators is deprecated Sup port for masks will be removed in 017 The generators have produced arrays of indices by default since 010 By Joel Nothman
• 1d arrays containing strings with dtypeobject as used in Pandas are now considered valid classification targets This fixes a regression from version 013 in some classifiers By Joel Nothman
• Fix wrong explainedvarianceratio attribute in RandomizedPCA By Alexandre Gramfort
• Fit alphas for each l1ratio instead of meanl1ratio inlinearmodelElasticNetCV and linearmodelLassoCV This changes the shape of alphas fromnalphas tonl1ratio nalphas if thel1ratio provided is a 1D array like object of length greater than one By Manoj Kumar
• FixlinearmodelElasticNetCV andlinearmodelLassoCV when fitting intercept and input data is sparse The automatic grid of alphas was not computed correctly and the scaling with normalize was wrong By Manoj Kumar
• Fix wrong maximal number of features drawn maxfeatures at each split for decision trees random forests and gradient tree boosting Previously the count for the number of drawn features started only after one non constant features in the split This bug fix will affect computational and generalization performance of those algorithms in the presence of constant features To get back previous generalization performance you should modify the value of maxfeatures By Arnaud Joly
• Fix wrong maximal number of features drawn maxfeatures at each split for ensemble ExtraTreesClassifier andensembleExtraTreesRegressor Previously only non constant features in the split was counted as drawn Now constant features are counted as drawn Furthermore at least one feature must be non constant in order to make a valid split This bug fix will affect computational and gen eralization performance of extra trees in the presence of constant features To get back previous generalization performance you should modify the value of maxfeatures By Arnaud Joly
• Fixutilscomputeclassweight whenclassweightauto Previously it was broken for input of noninteger dtype and the weighted array that was returned was wrong By Manoj Kumar
• FixcrossvalidationBootstrap to returnValueError whenntrain ntest n By Ronald Phlypo

11714 Version 014
August 7 2013
Changelog
• Missing values with sparse and dense matrices can be imputed with the transformer preprocessing
Imputer by Nicolas Trésegnie
• The core implementation of decisions trees has been rewritten from scratch allowing for faster tree induction
and lower memory consumption in all treebased estimators By Gilles Louppe
• AddedensembleAdaBoostClassifier andensembleAdaBoostRegressor by Noel Dawe and
Gilles Louppe See the AdaBoost section of the user guide for details and examples
• AddedgridsearchRandomizedSearchCV andgridsearchParameterSampler for random
ized hyperparameter optimization By Andreas Müller
• Added biclustering algorithms sklearnclusterbiclusterSpectralCoclustering and
sklearnclusterbiclusterSpectralBiclustering data generation methods sklearn
datasetsmakebiclusters andsklearndatasetsmakecheckerboard and scoring met
rics sklearnmetricsconsensusscore By Kemal Eren
• Added Restricted Boltzmann Machines neuralnetworkBernoulliRBM By Yann Dauphin

• Python 3 support by Justin Vincent Lars Buitinck Subhodeep Moitra and Olivier Grisel All tests now pass under Python 33
• Ability to pass one penalty alpha value per target in linearmodelRidge by eickenberg and Mathieu Blondel
• Fixedsklearnlinearmodelstochasticgradientpy L2 regularization issue minor practical significance By Norbert Crombach and Mathieu Blondel
• Added an interactive version of Andreas Müller's Machine Learning Cheat Sheet for scikitlearn to the documentation See Choosing the right estimator By Jaques Grobler
•gridsearchGridSearchCV andcrossvalidationcrossvalscore now support the use of advanced scoring function such as area under the ROC curve and fbeta scores See The scoring parameter defining model evaluation rules for details By Andreas Müller and Lars Buitinck Passing a function from sklearnmetrics asscorefunc is deprecated
• Multilabel classification output is now supported by metricsaccuracyscore metricszerooneloss metricsf1score metricsfbetascore metrics classificationreport metricsprecisionscore andmetricsrecallscore by Arnaud Joly
• Two new metrics metricshammingloss andmetricsjaccardsimilarityscore are added with multilabel support by Arnaud Joly
• Speed and memory usage improvements in featureextractiontextCountVectorizer and featureextractiontextTfidfVectorizer by Jochen Wersdörfer and Roman Sinayev
• Themindf parameter in featureextractiontextCountVectorizer and featureextractiontextTfidfVectorizer which used to be 2 has been reset to 1 to avoid unpleasant surprises empty vocabularies for novice users who try it out on tiny document collections A value of at least 2 is still recommended for practical use
•svmLinearSVC linearmodelSGDClassifier andlinearmodelSGDRegressor now have asparsify method that converts their coef into a sparse matrix meaning stored models trained using these estimators can be made much more compact
•linearmodelSGDClassifier now produces multiclass probability estimates when trained under log loss or modified Huber loss
• Hyperlinks to documentation in example code on the website by Martin Luessi
• Fixed bug in preprocessingMinMaxScaler causing incorrect scaling of the features for nondefault featurerange settings By Andreas Müller
•maxfeatures intreeDecisionTreeClassifier treeDecisionTreeRegressor and all derived ensemble estimators now supports percentage values By Gilles Louppe
• Performance improvements in isotonicIsotonicRegression by Nelle Varoquaux
•metricsaccuracyscore has an option normalize to return the fraction or the number of correctly classified sample by Arnaud Joly
• Addedmetricslogloss that computes log loss aka crossentropy loss By Jochen Wersdörfer and Lars Buitinck
• A bug that caused ensembleAdaBoostClassifier 's to output incorrect probabilities has been fixed
• Feature selectors now share a mixin providing consistent transform inversetransform and getsupport methods By Joel Nothman
• A fittedgridsearchGridSearchCV orgridsearchRandomizedSearchCV can now generally be pickled By Joel Nothman

• Refactored and vectorized implementation of metricsroccurve andmetrics
precisionrecallcurve By Joel Nothman
• The new estimator sklearndecompositionTruncatedSVD performs dimensionality reduction using
SVD on sparse matrices and can be used for latent semantic analysis LSA By Lars Buitinck
• Added selfcontained example of outofcore learning on text data Outofcore classification of text documents
By Eustache Diemert
• The default number of components for sklearndecompositionRandomizedPCA is now correctly
documented to be nfeatures This was the default behavior so programs using it will continue to work as
they did
•sklearnclusterKMeans now fits several orders of magnitude faster on sparse data the speedup depends
on the sparsity By Lars Buitinck
• Reduce memory footprint of FastICA by Denis Engemann and Alexandre Gramfort
• Verbose output in sklearnensemblegradientboosting now uses a column format and prints
progress in decreasing frequency It also shows the remaining time By Peter Prettenhofer
•sklearnensemblegradientboosting provides outofbag improvement oobimprovement
rather than the OOB score for model selection An example that shows how to use OOB estimates to select the
number of trees was added By Peter Prettenhofer
• Most metrics now support string labels for multiclass classification by Arnaud Joly and Lars Buitinck
• New OrthogonalMatchingPursuitCV class by Alexandre Gramfort and Vlad Niculae
• Fixed a bug in sklearncovarianceGraphLassoCV the ‘alphas’ parameter now works as expected
when given a list of values By Philippe Gervais
• Fixed an important bug in sklearncovarianceGraphLassoCV that prevented all folds provided by
a CV object to be used only the first 3 were used When providing a CV object execution time may thus
increase significantly compared to the previous version bug results are correct now By Philippe Gervais
•crossvalidationcrossvalscore and thegridsearch module is now tested with multi
output data by Arnaud Joly
•datasetsmakemultilabelclassification can now return the output in label indicator multil
abel format by Arnaud Joly
• Knearest neighbors neighborsKNeighborsRegressor andneighbors
RadiusNeighborsRegressor and radius neighbors neighborsRadiusNeighborsRegressor
andneighborsRadiusNeighborsClassifier support multioutput data by Arnaud Joly
• Random state in LibSVMbased estimators svmSVC NuSVC OneClassSVM svmSVR svmNuSVR
can now be controlled This is useful to ensure consistency in the probability estimates for the classifiers trained
withprobabilityTrue By Vlad Niculae
• Outofcore learning support for discrete naive Bayes classifiers sklearnnaivebayes
MultinomialNB andsklearnnaivebayesBernoulliNB by adding the partialfit
method by Olivier Grisel
• New website design and navigation by Gilles Louppe Nelle Varoquaux Vincent Michel and Andreas Müller
• Improved documentation on multiclass multilabel and multioutput classification by Yannick Schwartz and
Arnaud Joly
• Better input and error handling in the metrics module by Arnaud Joly and Joel Nothman
• Speed optimization of the hmm module by Mikhail Korobov
• Significant speed improvements for sklearnclusterDBSCAN by cleverless

API changes summary
• Theaucscore was renamed rocaucscore
• Testing scikitlearn with sklearntest is deprecated Use nosetests sklearn from the command
line
• Feature importances in treeDecisionTreeClassifier treeDecisionTreeRegressor and all
derived ensemble estimators are now computed on the fly when accessing the featureimportances
attribute Setting computeimportancesTrue is no longer required By Gilles Louppe
•linearmodellassopath andlinearmodelenetpath can return its results in the same format
as that oflinearmodellarspath This is done by setting the returnmodels parameter to False
By Jaques Grobler and Alexandre Gramfort
•gridsearchIterGrid was renamed to gridsearchParameterGrid
• Fixed bug in KFold causing imperfect class balance in some cases By Alexandre Gramfort and Tadej Janež
•sklearnneighborsBallTree has been refactored and a sklearnneighborsKDTree has been
added which shares the same interface The Ball Tree now works with a wide variety of distance metrics
Both classes have many new methods including singletree and dualtree queries breadthfirst and depthfirst
searching and more advanced queries such as kernel density estimation and 2point correlation functions By
Jake Vanderplas
• Support for scipyspatialcKDTree within neighbors queries has been removed and the functionality replaced
with the new KDTree class
•sklearnneighborsKernelDensity has been added which performs efficient kernel density estima
tion with a variety of kernels
•sklearndecompositionKernelPCA now always returns output with ncomponents components
unless the new parameter removezeroeig is set toTrue This new behavior is consistent with the way
kernel PCA was always documented previously the removal of components with zero eigenvalues was tacitly
performed on all data
•gcvmodeauto no longer tries to perform SVD on a densified sparse matrix in sklearn
linearmodelRidgeCV
• Sparse matrix support in sklearndecompositionRandomizedPCA is now deprecated in favor of the
newTruncatedSVD
•crossvalidationKFold andcrossvalidationStratifiedKFold now enforce nfolds
 2 otherwise a ValueError is raised By Olivier Grisel
•datasetsloadfiles ’scharset andcharseterrors parameters were renamed encoding and
decodeerrors
• Attribute oobscore insklearnensembleGradientBoostingRegressor and
sklearnensembleGradientBoostingClassifier is deprecated and has been replaced by
oobimprovement
• Attributes in OrthogonalMatchingPursuit have been deprecated copyX Gram and precomputegram
renamed precompute for consistency See 2224
•sklearnpreprocessingStandardScaler now converts integer input to float and raises a warning
Previously it rounded for dense integer input
•sklearnmulticlassOneVsRestClassifier now has a decisionfunction method This
will return the distance of each sample from the decision boundary for each class as long as the underlying
estimators implement the decisionfunction method By Kyle Kastner
• Better input validation warning on unexpected shapes for y

11715 Version 0131
February 23 2013
The 0131 release only fixes some bugs and does not add any new functionality
Changelog
• Fixed a testing error caused by the function crossvalidationtraintestsplit being interpreted
as a test by Yaroslav Halchenko
• Fixed a bug in the reassignment of small clusters in the clusterMiniBatchKMeans by Gael Varoquaux
• Fixed default value of gamma indecompositionKernelPCA by Lars Buitinck
• Updated joblib to 070d by Gael Varoquaux
• Fixed scaling of the deviance in ensembleGradientBoostingClassifier by Peter Prettenhofer
• Better tiebreaking in multiclassOneVsOneClassifier by Andreas Müller
• Other small improvements to tests and documentation

11716 Version 013
January 21 2013
New Estimator Classes
•dummyDummyClassifier anddummyDummyRegressor two dataindependent predictors by Mathieu Blondel Useful to sanitycheck your estimators See Dummy estimators in the user guide Multioutput support added by Arnaud Joly
•decompositionFactorAnalysis a transformer implementing the classical factor analysis by Christian Osendorfer and Alexandre Gramfort See Factor Analysis in the user guide
•featureextractionFeatureHasher a transformer implementing the “hashing trick” for fast lowmemory feature extraction from string fields by Lars Buitinck and featureextractiontext HashingVectorizer for text documents by Olivier Grisel See Feature hashing andVectorizing a large text corpus with the hashing trick for the documentation and sample usage
•pipelineFeatureUnion a transformer that concatenates results of several other transformers by Andreas Müller See FeatureUnion composite feature spaces in the user guide
•randomprojectionGaussianRandomProjection randomprojection SparseRandomProjection and the function randomprojection johnsonlindenstraussmindim The first two are transformers implementing Gaussian and sparse random projection matrix by Olivier Grisel and Arnaud Joly See Random Projection in the user guide
•kernelapproximationNystroem a transformer for approximating arbitrary kernels by Andreas Müller See Nystroem Method for Kernel Approximation in the user guide

•preprocessingOneHotEncoder a transformer that computes binary encodings of categorical features
by Andreas Müller See Encoding categorical features in the user guide
•linearmodelPassiveAggressiveClassifier and linearmodel
PassiveAggressiveRegressor predictors implementing an efficient stochastic optimization for
linear models by Rob Zinkov and Mathieu Blondel See Passive Aggressive Algorithms in the user guide
•ensembleRandomTreesEmbedding a transformer for creating highdimensional sparse representations
using ensembles of totally random trees by Andreas Müller See Totally Random Trees Embedding in the user
guide
•manifoldSpectralEmbedding and function manifoldspectralembedding implementing
the “laplacian eigenmaps” transformation for nonlinear dimensionality reduction by Wei Li See Spectral
Embedding in the user guide
•isotonicIsotonicRegression by Fabian Pedregosa Alexandre Gramfort and Nelle Varoquaux
Changelog
•metricszerooneloss formerlymetricszeroone now has option for normalized output that
reports the fraction of misclassifications rather than the raw number of misclassifications By Kyle Beauchamp
•treeDecisionTreeClassifier and all derived ensemble models now support sample weighting by
Noel Dawe and Gilles Louppe
• Speedup improvement when using bootstrap samples in forests of randomized trees by Peter Prettenhofer and
Gilles Louppe
• Partial dependence plots for Gradient Tree Boosting inensemble
partialdependencepartialdependence by Peter Prettenhofer See
sphxglrautoexamplesensembleplotpartialdependencepy for an example
• The table of contents on the website has now been made expandable by Jaques Grobler
•featureselectionSelectPercentile now breaks ties deterministically instead of returning all
equally ranked features
•featureselectionSelectKBest andfeatureselectionSelectPercentile are more
numerically stable since they use scores rather than pvalues to rank results This means that they might
sometimes select different features than they did previously
• Ridge regression and ridge classification fitting with sparsecg solver no longer has quadratic memory com
plexity by Lars Buitinck and Fabian Pedregosa
• Ridge regression and ridge classification now support a new fast solver called lsqr by Mathieu Blondel
• Speed up of metricsprecisionrecallcurve by Conrad Lee
• Added support for readingwriting svmlight files with pairwise preference attribute qid in svmlight file format
indatasetsdumpsvmlightfile anddatasetsloadsvmlightfile by Fabian Pedregosa
• Faster and more robust metricsconfusionmatrix andClustering performance evaluation by Wei Li
•crossvalidationcrossvalscore now works with precomputed kernels and affinity matrices by
Andreas Müller
• LARS algorithm made more numerically stable with heuristics to drop regressors too correlated as well as to
stop the path when numerical noise becomes predominant by Gael Varoquaux
• Faster implementation of metricsprecisionrecallcurve by Conrad Lee
• New kernel metricschi2kernel by Andreas Müller often used in computer vision applications

• Fix of longstanding bug in naivebayesBernoulliNB fixed by Shaun Jackman
• Implemented predictproba inmulticlassOneVsRestClassifier by Andrew Winterman
• Improve consistency in gradient boosting estimators ensembleGradientBoostingRegressor and ensembleGradientBoostingClassifier use the estimator treeDecisionTreeRegressor instead of the treetreeTree data structure by Arnaud Joly
• Fixed a floating point exception in the decision trees module by Seberg
• Fixmetricsroccurve fails when ytrue has only one class by Wei Li
• Add the metricsmeanabsoluteerror function which computes the mean absolute error The metricsmeansquarederror metricsmeanabsoluteerror andmetricsr2score metrics support multioutput by Arnaud Joly
• Fixedclassweight support insvmLinearSVC andlinearmodelLogisticRegression by Andreas Müller The meaning of classweight was reversed as erroneously higher weight meant less positives of a given class in earlier releases
• Improve narrative documentation and consistency in sklearnmetrics for regression and classification metrics by Arnaud Joly
• Fixed a bug in sklearnsvmSVC when using csrmatrices with unsorted indices by Xinfan Meng and An dreas Müller
•MiniBatchKMeans Add random reassignment of cluster centers with little observations attached to them by Gael Varoquaux

API changes summary

• Renamed all occurrences of natoms toncomponents for consistency This applies to decompositionDictionaryLearning decomposition MiniBatchDictionaryLearning decompositiondictlearning decomposition dictlearningonline
• Renamed all occurrences of maxiters tomaxiter for consistency This applies to semisupervisedLabelPropagation andsemisupervisedlabelpropagation LabelSpreading
• Renamed all occurrences of learnrate tolearningrate for consistency in ensemble BaseGradientBoosting andensembleGradientBoostingRegressor
• The module sklearnlinearmodelsparse is gone Sparse matrix support was already integrated into the “regular” linear models
•sklearnmetricsmeansquareerror which incorrectly returned the accumulated error was re moved Use meansquarederror instead
• Passingclassweight parameters to fit methods is no longer supported Pass them to estimator construc tors instead
• GMMs no longer have decode andrvs methods Use the score predict orsample methods instead
• Thesolver fit option in Ridge regression and classification is now deprecated and will be removed in v014 Use the constructor option instead
•featureextractiontextDictVectorizer now returns sparse matrices in the CSR format in stead of COO
• Renamed kincrossvalidationKFold andcrossvalidationStratifiedKFold to nfolds renamednbootstraps toniter incrossvalidationBootstrap

• Renamed all occurrences of niterations toniter for consistency This applies to crossvalidationShuffleSplit crossvalidationStratifiedShuffleSplit utilsrandomizedrangefinder andutilsrandomizedsvd
• Replaced rho inlinearmodelElasticNet andlinearmodelSGDClassifier by l1ratio Therho parameter had different meanings l1ratio was introduced to avoid confu sion It has the same meaning as previously rho inlinearmodelElasticNet and1rho in linearmodelSGDClassifier
•linearmodelLassoLars andlinearmodelLars now store a list of paths in the case of multiple targets rather than an array of paths
• The attribute gmm ofhmmGMMHMM was renamed to gmm to adhere more strictly with the API
•clusterspectralembedding was moved to manifoldspectralembedding
• Renamed eigtol inmanifoldspectralembedding clusterSpectralClustering to eigentol renamedmode toeigensolver
• Renamed mode inmanifoldspectralembedding andclusterSpectralClustering to eigensolver
•classes andnclasses attributes of treeDecisionTreeClassifier and all derived ensemble models are now flat in case of single output problems and nested in case of multioutput problems
• Theestimators attribute of ensemblegradientboostingGradientBoostingRegressor andensemblegradientboostingGradientBoostingClassifier is now an array of class’treeDecisionTreeRegressor’
• Renamed chunksize tobatchsize indecompositionMiniBatchDictionaryLearning anddecompositionMiniBatchSparsePCA for consistency
•svmSVC andsvmNuSVC now provide a classes attribute and support arbitrary dtypes for labels y Also the dtype returned by predict now reflects the dtype of yduringfit used to be npfloat
• Changed default testsize in crossvalidationtraintestsplit to None added pos sibility to infer testsize fromtrainsize incrossvalidationShuffleSplit and crossvalidationStratifiedShuffleSplit
• Renamed function sklearnmetricszeroone tosklearnmetricszerooneloss Be aware that the default behavior in sklearnmetricszerooneloss is different from sklearn metricszeroone normalizeFalse is changed to normalizeTrue
• Renamed function metricszeroonescore tometricsaccuracyscore
•datasetsmakecircles now has the same number of inner and outer points
• In the Naive Bayes classifiers the classprior parameter was moved from fit toinit

11717 Version 0121
October 8 2012
The 0121 release is a bugfix release with no additional features but is instead a set of bug fixes
Changelog
• Improved numerical stability in spectral embedding by Gael Varoquaux
• Doctest under windows 64bit by Gael Varoquaux
• Documentation fixes for elastic net by Andreas Müller and Alexandre Gramfort
• Proper behavior with fortranordered NumPy arrays by Gael Varoquaux
• Make GridSearchCV work with nonCSR sparse matrix by Lars Buitinck
• Fix parallel computing in MDS by Gael Varoquaux

• Fix Unicode support in count vectorizer by Andreas Müller
• Fix MinCovDet breaking with Xshape 3 1 by Virgile Fritsch
• Fix clone of SGD objects by Peter Prettenhofer
• Stabilize GMM by Virgile Fritsch
People
• 14 Peter Prettenhofer

• 1 Gilles Louppe
• 1 Mathieu Blondel
11718 Version 012
September 4 2012
Changelog
• Various speed improvements of the decision trees module by Gilles Louppe
•ensembleGradientBoostingRegressor andensembleGradientBoostingClassifier
now support feature subsampling via the maxfeatures argument by Peter Prettenhofer
• Added Huber and Quantile loss functions to ensembleGradientBoostingRegressor by Peter Pret
tenhofer
•Decision trees andforests of randomized trees now support multioutput classification and regression problems
by Gilles Louppe
• AddedpreprocessingLabelEncoder a simple utility class to normalize labels or transform non
numerical labels by Mathieu Blondel
• Added the epsiloninsensitive loss and the ability to make probabilistic predictions with the modified huber loss
inStochastic Gradient Descent by Mathieu Blondel
• Added Multidimensional Scaling MDS by Nelle Varoquaux
• SVMlight file format loader now detects compressed gzipbzip2 files and decompresses them on the fly by
Lars Buitinck
• SVMlight file format serializer now preserves double precision floating point values by Olivier Grisel
• A common testing framework for all estimators was added by Andreas Müller
• Understandable error messages for estimators that do not accept sparse input by Gael Varoquaux
• Speedups in hierarchical clustering by Gael Varoquaux In particular building the tree now supports early
stopping This is useful when the number of clusters is not small compared to the number of samples

• Add MultiTaskLasso and MultiTaskElasticNet for joint feature selection by Alexandre Gramfort
• Addedmetricsaucscore andmetricsaverageprecisionscore convenience functions by
Andreas Müller
• Improved sparse matrix support in the Feature selection module by Andreas Müller
• New word boundariesaware character ngram analyzer for the Text feature extraction module by kernc
• Fixed bug in spectral clustering that led to single point clusters by Andreas Müller
• InfeatureextractiontextCountVectorizer added an option to ignore infrequent words
mindf by Andreas Müller
• Add support for multiple targets in some linear models ElasticNet Lasso and OrthogonalMatchingPursuit by
Vlad Niculae and Alexandre Gramfort
• Fixes indecompositionProbabilisticPCA score function by Wei Li
• Fixed feature importance computation in Gradient Tree Boosting
API changes summary
• The oldscikitslearn package has disappeared all code should import from sklearn instead which
was introduced in 09
• Inmetricsroccurve thethresholds array is now returned with it's order reversed in order to keep
it consistent with the order of the returned fpr andtpr
• Inhmm objects like hmmGaussianHMM hmmMultinomialHMM etc all parameters must be passed to
the object when initialising it and not through fit Nowfit will only accept the data as an input parameter
• For all SVM classes a faulty behavior of gamma was fixed Previously the default gamma value was only
computed the first time fit was called and then stored It is now recalculated on every call to fit
• AllBase classes are now abstract meta classes so that they can not be instantiated
•clusterwardtree now also returns the parent array This is necessary for earlystopping in which case
the tree is not completely built
• InfeatureextractiontextCountVectorizer the parameters minn andmaxn were joined to
the parameter ngramrange to enable gridsearching both at once
• InfeatureextractiontextCountVectorizer words that appear only in one document are now
ignored by default To reproduce the previous behavior set mindf1
• Fixed API inconsistency linearmodelSGDClassifierpredictproba now returns 2d array
when fit on two classes
• Fixed API inconsistency discriminantanalysisQuadraticDiscriminantAnalysis
decisionfunction anddiscriminantanalysisLinearDiscriminantAnalysis
decisionfunction now return 1d arrays when fit on two classes
• Grid of alphas used for fitting linearmodelLassoCV andlinearmodelElasticNetCV is now
stored in the attribute alphas rather than overriding the init parameter alphas
• Linear models when alpha is estimated by crossvalidation store the estimated value in the alpha attribute
rather than just alpha orbestalpha
•ensembleGradientBoostingClassifier now supports ensemble
GradientBoostingClassifierstagedpredictproba and ensemble
GradientBoostingClassifierstagedpredict

•svmsparseSVC and other sparse SVM classes are now deprecated The all classes in the Support Vector Machines module now automatically select the sparse or dense representation base on the input
• All clustering algorithms now interpret the array Xgiven tofit as input data in particular cluster SpectralClustering andclusterAffinityPropagation which previously expected affinity matrices
• For clustering algorithms that take the desired number of clusters as a parameter this parameter is now called nclusters

11719 Version 011
May 7 2012
Changelog
Highlights
• Gradient boosted regression trees Gradient Tree Boosting for classification and regression by Peter Pretten
hofer and Scott White
• Simple dictbased feature loader with support for categorical variables featureextraction
DictVectorizer by Lars Buitinck
• Added Matthews correlation coefficient metricsmatthewscorrcoef and added macro and micro av
erage options to metricsprecisionscore metricsrecallscore andmetricsf1score
by Satrajit Ghosh
•Out of Bag Estimates of generalization error for Ensemble methods by Andreas Müller
• Randomized sparse linear models for feature selection by Alexandre Gramfort and Gael Varoquaux
•Label Propagation for semisupervised learning by Clay Woolam Note the semisupervised API is still work
in progress and may change

• Added BICAIC model selection to classical Gaussian mixture models and unified the API with the remainder of scikitlearn by Bertrand Thirion
• AddedsklearncrossvalidationStratifiedShuffleSplit which is a sklearn crossvalidationShuffleSplit with balanced splits by Yannick Schwartz
•sklearnneighborsNearestCentroid classifier added along with a shrinkthreshold parameter which implements shrunken centroid classification by Robert Layton

Other changes

• Merged dense and sparse implementations of Stochastic Gradient Descent module and exposed utility extension types for sequential datasets seqdataset and weight vectors weightvector by Peter Prettenhofer
• Addedpartialfit support for onlineminibatch learning and warmstart to the Stochastic Gradient Descent module by Mathieu Blondel
• Dense and sparse implementations of Support Vector Machines classes and linearmodel LogisticRegression merged by Lars Buitinck
• Regressors can now be used as base estimator in the Multiclass and multilabel algorithms module by Mathieu Blondel
• Added njobs option to metricspairwisepairwisedistances andmetricspairwise pairwisekernels for parallel computation by Mathieu Blondel
•Kmeans can now be run in parallel using the njobs argument to either Kmeans orKMeans by Robert Layton
• Improved Crossvalidation evaluating estimator performance andTuning the hyperparameters of an estimator documentation and introduced the new crossvalidationtraintestsplit helper function by Olivier Grisel
•svmSVC memberscoef andintercept changed sign for consistency with decisionfunction forkernellinear coef was fixed in the onevsone case by Andreas Müller
• Performance improvements to efficient leaveoneout crossvalidated Ridge regression esp for the nsamples nfeatures case inlinearmodelRidgeCV by Reuben FletcherCostin
• Refactoring and simplification of the Text feature extraction API and fixed a bug that caused possible negative IDF by Olivier Grisel
• Beam pruning option in BaseHMM module has been removed since it is difficult to Cythonize If you are interested in contributing a Cython version you can use the python version in the git history as a reference
• Classes in Nearest Neighbors now support arbitrary Minkowski metric for nearest neighbors searches The metric can be specified by argument p

API changes summary

•covarianceEllipticEnvelop is now deprecated Please use covarianceEllipticEnvelope instead
•NeighborsClassifier andNeighborsRegressor are gone in the module Nearest Neighbors Use the classes KNeighborsClassifier RadiusNeighborsClassifier KNeighborsRegressor andorRadiusNeighborsRegressor instead
• Sparse classes in the Stochastic Gradient Descent module are now deprecated

• InmixtureGMM mixtureDPGMM andmixtureVBGMM parameters must be passed to an object when initialising it and not through fit Nowfit will only accept the data as an input parameter
• methods rvs anddecode inGMM module are now deprecated sample andscore orpredict should be used instead
• attributescores andpvalues in univariate feature selection objects are now deprecated scores or pvalues should be used instead
• InLogisticRegression LinearSVC SVC andNuSVC theclassweight parameter is now an ini tialization parameter not a parameter to fit This makes grid searches over this parameter possible
• LFWdata is now always shape nsamples nfeatures to be consistent with the Olivetti faces dataset Use images andpairs attribute to access the natural images shapes instead
• InsvmLinearSVC the meaning of the multiclass parameter changed Options now are ovr and crammersinger withovr being the default This does not change the default behavior but hopefully is less confusing
• Class featureselectiontextVectorizer is deprecated and replaced by featureselectiontextTfidfVectorizer
• The preprocessor analyzer nested structure for text feature extraction has been removed All those features are now directly passed as flat constructor arguments to featureselectiontextTfidfVectorizer andfeatureselectiontextCountVectorizer in particular the following parameters are now used
•analyzer can beword orchar to switch the default analysis scheme or use a specific python callable as previously
•tokenizer andpreprocessor have been introduced to make it still possible to customize those steps with the new API
•input explicitly control how to interpret the sequence passed to fit andpredict filenames file objects or direct byte or Unicode strings
• charset decoding is explicit and strict by default
• thevocabulary fitted or not is now stored in the vocabulary attribute to be consistent with the project conventions
• Class featureselectiontextTfidfVectorizer now derives directly from featureselectiontextCountVectorizer to make grid search trivial
• methodsrvs inBaseHMM module are now deprecated sample should be used instead
• Beam pruning option in BaseHMM module is removed since it is difficult to be Cythonized If you are inter ested you can look in the history codes by git
• The SVMlight format loader now supports files with both zerobased and onebased column indices since both occur “in the wild”
• Arguments in class ShuffleSplit are now consistent with StratifiedShuffleSplit Arguments testfraction andtrainfraction are deprecated and renamed to testsize andtrainsize and can accept both float andint
• Arguments in class Bootstrap are now consistent with StratifiedShuffleSplit Arguments ntest andntrain are deprecated and renamed to testsize andtrainsize and can accept both float andint
• Argument padded to classes in Nearest Neighbors to specify an arbitrary Minkowski metric for nearest neigh bors searches

11720 Version 010
January 11 2012
Changelog
• Python 25 compatibility was dropped the minimum Python version needed to use scikitlearn is now 26
•Sparse inverse covariance estimation using the graph Lasso with associated crossvalidated estimator by Gael Varoquaux
• New Tree module by Brian Holt Peter Prettenhofer Satrajit Ghosh and Gilles Louppe The module comes with complete documentation and examples
• Fixed a bug in the RFE module by Gilles Louppe issue 378
• Fixed a memory leak in Support Vector Machines module by Brian Holt issue 367
• Faster tests by Fabian Pedregosa and others
• Silhouette Coefficient cluster analysis evaluation metric added as sklearnmetrics silhouettescore by Robert Layton
• Fixed a bug in Kmeans in the handling of the ninit parameter the clustering algorithm used to be run ninit times but the last solution was retained instead of the best solution by Olivier Grisel
• Minor refactoring in Stochastic Gradient Descent module consolidated dense and sparse predict methods En hanced test time performance by converting model parameters to fortranstyle arrays after fitting only multi class
• Adjusted Mutual Information metric added as sklearnmetricsadjustedmutualinfoscore by Robert Layton
• Models like SVCSVRLinearSVCLogisticRegression from libsvmliblinear now support scaling of C regular ization parameter by the number of samples by Alexandre Gramfort
• New Ensemble Methods module by Gilles Louppe and Brian Holt The module comes with the random forest algorithm and the extratrees method along with documentation and examples

•Novelty and Outlier Detection outlier and novelty detection by Virgile Fritsch
•Kernel Approximation a transform implementing kernel approximation for fast SGD on nonlinear kernels by Andreas Müller
• Fixed a bug due to atom swapping in Orthogonal Matching Pursuit OMP by Vlad Niculae
•Sparse coding with a precomputed dictionary by Vlad Niculae
•Mini Batch KMeans performance improvements by Olivier Grisel
•Kmeans support for sparse matrices by Mathieu Blondel
• Improved documentation for developers and for the sklearnutils module by Jake Vanderplas
• Vectorized 20newsgroups dataset loader sklearndatasetsfetch20newsgroupsvectorized by Mathieu Blondel
•Multiclass and multilabel algorithms by Lars Buitinck
• Utilities for fast computation of mean and variance for sparse matrices by Mathieu Blondel
• Makesklearnpreprocessingscale andsklearnpreprocessingScaler work on sparse matrices by Olivier Grisel
• Feature importances using decision trees andor forest of trees by Gilles Louppe
• Parallel implementation of forests of randomized trees by Gilles Louppe
•sklearncrossvalidationShuffleSplit can subsample the train sets as well as the test sets by Olivier Grisel
• Errors in the build of the documentation fixed by Andreas Müller

API changes summary

Here are the code migration instructions when upgrading from scikitlearn version 09

• Some estimators that may overwrite their inputs to save memory previously had overwrite parameters these have been replaced with copy parameters with exactly the opposite meaning
This particularly affects some of the estimators in linearmodel The default behavior is still to copy everything passed in
• The SVMlight dataset loader sklearndatasetsloadsvmlightfile no longer supports loading two files at once use loadsvmlightfiles instead Also the unused buffermb parameter is gone
• Sparse estimators in the Stochastic Gradient Descent module use dense parameter vector coef instead of sparsecoef This significantly improves test time performance
• The Covariance estimation module now has a robust estimator of covariance the Minimum Covariance Deter minant estimator
• Cluster evaluation metrics in metricscluster have been refactored but the changes are backwards compat ible They have been moved to the metricsclustersupervised along with metricscluster unsupervised which contains the Silhouette Coefficient
• Thepermutationtestscore function now behaves the same way as crossvalscore ie uses the mean score across the folds
• Cross Validation generators now use integer indices indicesTrue by default instead of boolean masks This make it more intuitive to use with sparse matrix data

• The functions used for sparse coding sparseencode andsparseencodeparallel have been com
bined intosklearndecompositionsparseencode and the shapes of the arrays have been trans
posed for consistency with the matrix factorization setting as opposed to the regression setting
• Fixed an offbyone error in the SVMlightLibSVM file format handling files generated using sklearn
datasetsdumpsvmlightfile should be regenerated They should continue to work but acciden
tally had one extra column of zeros prepended
•BaseDictionaryLearning class replaced by SparseCodingMixin
•sklearnutilsextmathfastsvd has been renamed sklearnutilsextmath
randomizedsvd and the default oversampling is now fixed to 10 additional random vectors instead
of doubling the number of components to extract The new behavior follows the reference paper

11721 Version 09
September 21 2011
scikitlearn 09 was released on September 2011 three months after the 08 release and includes the new modules Manifold learning The Dirichlet Process as well as several new algorithms and documentation improvements This release also includes the dictionarylearning work developed by Vlad Niculae as part of the Google Summer of Code program
117 Previous Releases 133

Changelog
• New Manifold learning module by Jake Vanderplas and Fabian Pedregosa
• New Dirichlet Process Gaussian Mixture Model by Alexandre Passos

scikitlearn user guide Release 0213
•Nearest Neighbors module refactoring by Jake Vanderplas general refactoring support for sparse matrices in input speed and documentation improvements See the next section for a full list of API changes
• Improvements on the Feature selection module by Gilles Louppe refactoring of the RFE classes documentation rewrite increased efficiency and minor API changes
•Sparse principal components analysis SparsePCA and MiniBatchSparsePCA by Vlad Niculae Gael Varoquaux and Alexandre Gramfort
• Printing an estimator now behaves independently of architectures and Python version thanks to Jean Kossaifi
•Loader for libsvmsvmlight format by Mathieu Blondel and Lars Buitinck
• Documentation improvements thumbnails in example gallery by Fabian Pedregosa
• Important bugfixes in Support Vector Machines module segfaults bad performance by Fabian Pedregosa
• Added Multinomial Naive Bayes andBernoulli Naive Bayes by Lars Buitinck
• Text feature extraction optimizations by Lars Buitinck
• ChiSquare feature selection featureselectionunivariateselectionchi2 by Lars Buitinck
•Generated datasets module refactoring by Gilles Louppe
•Multiclass and multilabel algorithms by Mathieu Blondel
• Ball tree rewrite by Jake Vanderplas
• Implementation of DBSCAN algorithm by Robert Layton
• Kmeans predict and transform by Robert Layton
• Preprocessing module refactoring by Olivier Grisel
• Faster mean shift by Conrad Lee
• NewBootstrap Random permutations crossvalidation aka Shuffle Split and various other improvements in cross validation schemes by Olivier Grisel and Gael Varoquaux
• Adjusted Rand index and VMeasure clustering evaluation metrics by Olivier Grisel
• AddedOrthogonal Matching Pursuit by Vlad Niculae
• Added 2Dpatch extractor utilities in the Feature extraction module by Vlad Niculae
• Implementation of linearmodelLassoLarsCV crossvalidated Lasso solver using the Lars algorithm andlinearmodelLassoLarsIC BICAIC model selection in Lars by Gael Varoquaux and Alexandre Gramfort
• Scalability improvements to metricsroccurve by Olivier Hervieu
• Distance helper functions metricspairwisepairwisedistances andmetricspairwise pairwisekernels by Robert Layton
•MiniBatch KMeans by Nelle Varoquaux and Peter Prettenhofer
• mldata utilities by Pietro Berkes
• olivettifaces by David WardeFarley

API changes summary

Here are the code migration instructions when upgrading from scikitlearn version 08

scikitlearn user guide Release 0213
• Thescikitslearn package was renamed sklearn There is still a scikitslearn package alias for
backward compatibility
Thirdparty projects with a dependency on scikitlearn 09 should upgrade their codebase For instance under
Linux MacOSX just run make a backup first
find name py xargs sed i s bscikitslearn bsklearng
• Estimators no longer accept model parameters as fit arguments instead all parameters must be only
be passed as constructor arguments or using the now public setparams method inherited from base
BaseEstimator
Some estimators can still accept keyword arguments on the fit but this is restricted to datadependent values
eg a Gram matrix or an affinity matrix that are precomputed from the Xdata matrix
• Thecrossval package has been renamed to crossvalidation although there is also a crossval
package alias in place for backward compatibility
Thirdparty projects with a dependency on scikitlearn 09 should upgrade their codebase For instance under
Linux MacOSX just run make a backup first
find name py xargs sed i s bcrossval bcrossvalidationg
• Thescorefunc argument of the sklearncrossvalidationcrossvalscore function is
now expected to accept ytest andypredicted as only arguments for classification and regression tasks
orXtest for unsupervised estimators
•gamma parameter for support vector machine algorithms is set to 1 nfeatures by default instead of 1
 nsamples
• Thesklearnhmm has been marked as orphaned it will be removed from scikitlearn in version 011 unless
someone steps up to contribute documentation examples and fix lurking numerical stability issues
•sklearnneighbors has been made into a submodule The two previously available estimators
NeighborsClassifier andNeighborsRegressor have been marked as deprecated Their function
ality has been divided among five new classes NearestNeighbors for unsupervised neighbors searches
KNeighborsClassifier RadiusNeighborsClassifier for supervised classification problems
andKNeighborsRegressor RadiusNeighborsRegressor for supervised regression problems
•sklearnballtreeBallTree has been moved to sklearnneighborsBallTree Using the
former will generate a warning
•sklearnlinearmodelLARS and related classes LassoLARS LassoLARSCV etc have been re
named tosklearnlinearmodelLars
• All distance metrics and kernels in sklearnmetricspairwise now have a Y parameter which by
default is None If not given the result is the distance or kernel similarity between each sample in Y If given
the result is the pairwise distance or kernel similarity between samples in X to Y
•sklearnmetricspairwisel1distance is now called manhattandistance and by default
returns the pairwise distance For the component wise distance set the parameter sumoverfeatures to
False
Backward compatibility package aliases and other deprecated classes and functions will be removed in version 011

scikitlearn user guide Release 0213
11722 Version 08
May 11 2011
scikitlearn 08 was released on May 2011 one month after the first “international” scikitlearn coding sprint and is marked by the inclusion of important modules Hierarchical clustering Cross decomposition Nonnegative matrix factorization NMF or NNMF initial support for Python 3 and by important enhancements and bug fixes
Changelog
Several new modules where introduced during this release
• New Hierarchical clustering module by Vincent Michel Bertrand Thirion Alexandre Gramfort and Gael Varoquaux
•Kernel PCA implementation by Mathieu Blondel
• labeledfacesinthewild by Olivier Grisel
• New Cross decomposition module by Edouard Duchesnay
•Nonnegative matrix factorization NMF or NNMF module Vlad Niculae
• Implementation of the Oracle Approximating Shrinkage algorithm by Virgile Fritsch in the Covariance estimationmodule
Some other modules benefited from significant improvements or cleanups
• Initial support for Python 3 builds and imports cleanly some modules are usable while others have failing tests by Fabian Pedregosa
•decompositionPCA is now usable from the Pipeline object by Olivier Grisel
• Guide How to optimize for speed by Olivier Grisel
• Fixes for memory leaks in libsvm bindings 64bit safer BallTree by Lars Buitinck
• bug and style fixing in Kmeans algorithm by Jan Schlüter
• Add attribute converged to Gaussian Mixture Models by Vincent Schut
• Implemented transform predictlogproba indiscriminantanalysis LinearDiscriminantAnalysis By Mathieu Blondel
• Refactoring in the Support Vector Machines module and bug fixes by Fabian Pedregosa Gael Varoquaux and Amit Aides
• Refactored SGD module removed code duplication better variable naming added interface for sample weight by Peter Prettenhofer
• Wrapped BallTree with Cython by Thouis Ray Jones
• Added function svml1minc by Paolo Losi
• Typos doc style etc by Yaroslav Halchenko Gael Varoquaux Olivier Grisel Yann Malet Nicolas Pinto Lars Buitinck and Fabian Pedregosa

11723 Version 07
March 2 2011
scikitlearn 07 was released in March 2011 roughly three months after the 06 release This release is marked by the speed improvements in existing algorithms like kNearest Neighbors and KMeans algorithm and by the inclusion of an efficient algorithm for computing the Ridge Generalized Cross Validation solution Unlike the preceding release no new modules where added to this release
Changelog
• Performance improvements for Gaussian Mixture Model sampling Jan Schlüter
• Implementation of efficient leaveoneout crossvalidated Ridge in linearmodelRidgeCV Mathieu Blondel

• Better handling of collinearity and early stopping in linearmodellarspath Alexandre Gramfort and Fabian Pedregosa
• Fixes for liblinear ordering of labels and sign of coefficients Dan Yamins Paolo Losi Mathieu Blondel and Fabian Pedregosa
• Performance improvements for Nearest Neighbors algorithm in highdimensional spaces Fabian Pedregosa
• Performance improvements for clusterKMeans Gael Varoquaux and James Bergstra
• Sanity checks for SVMbased classes Mathieu Blondel
• Refactoring of neighborsNeighborsClassifier andneighborskneighborsgraph added different algorithms for the kNearest Neighbor Search and implemented a more stable algorithm for finding barycenter weights Also added some developer documentation for this module see notesneighbors for more information Fabian Pedregosa
• Documentation improvements Added pcaRandomizedPCA andlinearmodel LogisticRegression to the class reference Also added references of matrices used for clustering and other fixes Gael Varoquaux Fabian Pedregosa Mathieu Blondel Olivier Grisel Virgile Fritsch Emmanuelle Gouillart
• Binded decisionfunction in classes that make use of liblinear dense and sparse variants like svm LinearSVC orlinearmodelLogisticRegression Fabian Pedregosa
• Performance and API improvements to metricseuclideandistances and topca RandomizedPCA James Bergstra
• Fix compilation issues under NetBSD Kamel Ibn Hassen Derouiche
• Allow input sequences of different lengths in hmmGaussianHMM Ron Weiss
• Fix bug in affinity propagation caused by incorrect indexing Xinfan Meng

11724 Version 06
December 21 2010
scikitlearn 06 was released on December 2010 It is marked by the inclusion of several new modules and a general renaming of old ones It is also marked by the inclusion of new example including applications to realworld datasets
Changelog
• New stochastic gradient descent module by Peter Prettenhofer The module comes with complete documentation and examples
• Improved svm module memory consumption has been reduced by 50 heuristic to automatically set class weights possibility to assign weights to samples see SVM Weighted samples for an example
• New Gaussian Processes module by Vincent Dubourg This module also has great documenta
tion and some very neat examples See examplegaussianprocessplotgpregressionpy or exam
plegaussianprocessplotgpprobabilisticclassificationafterregressionpy for a taste of what can be done
• It is now possible to use liblinear's Multiclass SVC option multiclass in svmLinearSVC
• New features and performance improvements of text feature extraction
• Improved sparse matrix support both in main classes gridsearchGridSearchCV as in modules sklearnsvmsparse and sklearnlinearmodelsparse
• Lots of cool new examples and a new section that uses realworld datasets was created These include Faces recognition example using eigenfaces and SVMs Species distribution modeling Libsvm GUI Wikipedia princi
pal eigenvector and others
• Faster Least Angle Regression algorithm It is now 2x faster than the R version on worst case and up to 10x times faster on some cases
• Faster coordinate descent algorithm In particular the full path version of lasso linearmodel lassopath is more than 200x times faster than before
• It is now possible to get probability estimates from a linearmodelLogisticRegression model
• module renaming the glm module has been renamed to linearmodel the gmm module has been included into the more general mixture model and the sgd module has been included in linearmodel
• Lots of bug fixes and documentation improvements

11725 Version 05
October 11 2010
Changelog
New classes
• Support for sparse matrices in some classifiers of modules svm andlinearmodel seesvm
sparseSVC svmsparseSVR svmsparseLinearSVC linearmodelsparseLasso
linearmodelsparseElasticNet
• NewpipelinePipeline object to compose different estimators
• Recursive Feature Elimination routines in module Feature selection
• Addition of various classes capable of cross validation in the linearmodel module linearmodel
LassoCV linearmodelElasticNetCV etc
• New more efficient LARS algorithm implementation The Lasso variant of the algorithm is also implemented
Seelinearmodellarspath linearmodelLars andlinearmodelLassoLars
• New Hidden Markov Models module see classes hmmGaussianHMM hmmMultinomialHMM hmm
GMMHMM
• New module featureextraction see class reference
• New FastICA algorithm in module sklearnfastica
Documentation
• Improved documentation for many modules now separating narrative documentation from the class reference
As an example see documentation for the SVM module and the complete class reference
Fixes
• API changes adhere variable names to PEP8 give more meaningful names
• Fixes for svm module to run on a shared memory context multiprocessing
• It is again possible to generate latex and thus PDF from the sphinx docs

scikitlearn user guide Release 0213
Examples
• new examples using some of the mlcomp datasets sphxglrautoexamplesmlcompsparsedocumentclassification pysince removed and Classification of text documents using sparse features
• Many more examples See here the full list of examples
External dependencies
• Joblib is now a dependency of this package although it is shipped with sklearnexternalsjoblib
Removed modules
• Module ann Artificial Neural Networks has been removed from the distribution Users wanting this sort of algorithms should take a look into pybrain
Misc
• New sphinx theme for the web page
Authors

11726 Version 04
August 26 2010
117 Previous Releases 143

Changelog
Major changes in this release include
• Coordinate Descent algorithm Lasso ElasticNet refactoring speed improvements roughly 100x times faster
• Coordinate Descent Refactoring and bug fixing for consistency with R's package GLMNET
• New metrics module
• New GMM module contributed by Ron Weiss
• Implementation of the LARS algorithm without Lasso variant for now
• featureselection module redesign
• Migration to GIT as version control system
• Removal of obsolete attrselect module
• Rename of private compiled extensions added underscore
• Removal of legacy unmaintained code
• Documentation improvements both docstring and rst
• Improvement of the build system to optionally link with MKL Also provide a lite BLAS implementation in case no systemwide BLAS is found
• Lots of new examples
• Many many bug fixes
Authors
The committer list for this release is the following preceded by number of commits
• 143 Fabian Pedregosa
• 35 Alexandre Gramfort
• 34 Olivier Grisel
• 11 Gael Varoquaux
• 5 Yaroslav Halchenko
• 2 Vincent Michel
• 1 Chris Filo Gorgolewski
11727 Earlier versions
Earlier versions included contributions by Fred Mailhot David Cooke David Huard Dave Morrill Ed Schofield Travis Oliphant Pearu Peterson

118 Roadmap
1181 Purpose of this document
This document list general directions that core contributors are interested to see developed in scikitlearn The fact that an item is listed here is in no way a promise that it will happen as resources are limited Rather it is an indication that help is welcomed on this topic
1182 Statement of purpose Scikitlearn in 2018
Eleven years after the inception of Scikitlearn much has changed in the world of machine learning Key changes include
• Computational tools The exploitation of GPUs distributed programming frameworks like ScalaSpark etc
• Highlevel Python libraries for experimentation processing and data management Jupyter notebook Cython Pandas Dask Numba
• Changes in the focus of machine learning research artificial intelligence applications where input structure is key with deep learning representation learning reinforcement learning domain transfer etc
A more subtle change over the last decade is that due to changing interests in ML PhD students in machine learning are more likely to contribute to PyTorch Dask etc than to Scikitlearn so our contributor pool is very different to a decade ago
Scikitlearn remains very popular in practice for trying out canonical machine learning techniques particularly for applications in experimental science and in data science A lot of what we provide is now very mature But it can be costly to maintain and we cannot therefore include arbitrary new implementations Yet Scikitlearn is also essential in defining an API framework for the development of interoperable machine learning components external to the core library
Thus our main goals in this era are to
• continue maintaining a highquality welldocumented collection of canonical tools for data processing and machine learning within the current scope ie rectangular data largely invariant to column and row order predicting targets with simple structure
• improve the ease for users to develop and publish external components
• improve interoperability with modern data science tools eg Pandas Dask and infrastructures eg distributed processing
Many of the more finegrained goals can be found under the API tag on the issue tracker
1183 Architectural general goals
The list is numbered not as an indication of the order of priority but to make referring to specific points easier Please add new entries only at the bottom
1 Everything in Scikitlearn should conform to our API contract
•Pipeline andFeatureUnion modify their input parameters in fit Fixing this requires making sure we have a good grasp of their use cases to make sure all current functionality is maintained 8157 7382
2 Improved handling of Pandas DataFrames and SparseDataFrames
• document current handling
• column reordering issue 7242

• avoiding unnecessary conversion to ndarray
• returning DataFrames from transformers 5523
• getting DataFrames from dataset loaders
• Sparse currently not considered
3 Improved handling of categorical features
• Treebased models should be able to handle both continuous and categorical features 4899
• In dataset loaders
• As generic transformers to be used with ColumnTransforms eg ordinal encoding supervised by correla
tion with target variable
4 Improved handling of missing data
• Making sure metaestimators are lenient towards missing data
• Nontrivial imputers
• Learners directly handling missing data
• An amputation sample generator to make parts of a dataset go missing
• Handling mixtures of categorical and continuous variables
5 Passing around information that is not X y Sample properties
• We need to be able to pass sample weights to scorers in cross validation
• We should have standardgeneralised ways of passing samplewise properties around in metaestimators
4497 7646
6 Passing around information that is not X y Feature properties
• Feature names or descriptions should ideally be available to fit for eg 6425 6424
• Perfeature handling eg “is this a nominal ordinal English language text” should also not need to be
provided to estimator constructors ideally but should be available as metadata alongside X 8480
7 Passing around information that is not X y Target information
• We have problems getting the full set of classes to all components when the data is splitsampled 6231
8100
• We have no way to handle a mixture of categorical and continuous targets
8 Make it easier for external users to write Scikitlearncompatible components
• More flexible estimator checks that do not select by estimator name 6599 6715
• Example of how to develop a metaestimator
• More selfsufficient running of scikitlearncontrib or a similar resource
9 Support resampling and sample reduction
• Allow subsampling of majority classes in a pipeline 3855
• Implement random forests with resampling 8732
10 Better interfaces for interactive development
• repr and HTML visualisations of estimators 6323
• Include plotting tools not just as examples 9173

11 Improved tools for model diagnostics and basic inference
• alternative feature importances implementations eg methods or wrappers
• better ways to handle validation sets when fitting
• better ways to find thresholds create decision rules 8614
12 Better tools for selecting hyperparameters with transductive estimators
• Grid search and cross validation are not applicable to most clustering tasks Stabilitybased selection is more relevant
13 Improved tracking of fitting
• Verbose is not very friendly and should use a standard logging library 6929
• Callbacks or a similar system would facilitate logging and early stopping
14 Distributed parallelism
• Joblib can now plug onto several backends some of them can distribute the computation across computers
• However we want to stay high level in scikitlearn
15 A way forward for more out of core
• Dask enables easy outofcore computation While the dask model probably cannot be adaptable to all machinelearning algorithms most machine learning is on smaller data than ETL hence we can maybe adapt to very large scale while supporting only a fraction of the patterns
16 Better support for manual and automatic pipeline building
• Easier way to construct complex pipelines and valid search spaces 7608 5082 8243
• provide search ranges for common estimators
• cf searchgrid
17 Support for working with pretrained models
• Estimator “freezing” In particular right now it’s impossible to clone a CalibratedClassifierCV with prefit 8370 6451
18 Backwardscompatible deserialization of some estimators
• Currently serialization with pickle breaks across versions While we may not be able to get around other limitations of pickle re security etc it would be great to offer crossversion safety from version 10 Note Gael and Olivier think that this can cause heavy maintenance burden and we should manage the tradeoffs A possible alternative is presented in the following point
19 Documentation and tooling for model lifecycle management
• Document good practices for model deployments and lifecycle before deploying a model snapshot the code versions numpy scipy scikitlearn custom code repo the training script and an alias on how to retrieve historical training data snapshot a copy of a small validation set snapshot of the predictions predicted probabilities for classifiers on that validation set
• Document and tools to make it easy to manage upgrade of scikitlearn versions
–Try to load the old pickle if it works use the validation set prediction snapshot to detect that the serialized model still behave the same
–If joblibload pickleload not work use the versioned control training script historical training set to retrain the model and use the validation set prediction snapshot to assert that it is possible to recover the previous predictive performance if this is not the case there is probably a bug in scikitlearn that needs to be reported

20 Optional Improve scikitlearn common tests suite to make sure that at least for frequently used models have stable predictions acrossversions to be discussed
• Extend documentation to mention how to deploy models in Pythonfree environments for instance ONNX and use the above best practices to assess predictive consistency between scikitlearn and ONNX prediction functions on validation set
• Document good practices to detect temporal distribution drift for deployed model and good practices for retraining on fresh data without causing catastrophic predictive performance regressions
21 More didactic documentation
• More and more options have been added to scikitlearn As a result the documentation is crowded which makes it hard for beginners to get the big picture Some work could be done in prioritizing the information
1184 Subpackagespecific goals
sklearncluster
• kmeans variants for nonEuclidean distances if we can show these have benefits beyond hierarchical clustering
sklearnensemble
• a stacking implementation
sklearnmodelselection
• multimetric scoring is slow 9326
• perhaps we want to be able to get back more than multiple metrics
• the handling of random states in CV splitters is a poor design and contradicts the validation of similar parameters in estimators
• exploit warmstarting and path algorithms so the benefits of EstimatorCV objects can be accessed via GridSearchCV and used in Pipelines 1626
• Crossvalidation should be able to be replaced by OOB estimates whenever a crossvalidation iterator is used
• Redundant computations in pipelines should be avoided related to point above cf daskml
sklearnneighbors
• Ability to substitute a customapproximateprecomputed nearest neighbors implementation for ours in allmost contexts that nearest neighbors are used for learning 10463
sklearnpipeline
• Performance issues with Pipelinememory
• see “Everything in Scikitlearn should conform to our API contract” above
119 Scikitlearn governance and decisionmaking
The purpose of this document is to formalize the governance process used by the scikitlearn project to clarify how decisions are made and how the various elements of our community interact This document establishes a decision making structure that takes into account feedback from all members of the community and strives to find consensus while avoiding any deadlocks

This is a meritocratic consensusbased community project Anyone with an interest in the project can join the com munity contribute to the project design and participate in the decision making process This document describes how that participation takes place and how to set about earning merit within the project community

1191 Roles And Responsibilities

Contributors

Contributors are community members who contribute in concrete ways to the project Anyone can become a contrib utor and contributions can take many forms – not only code – as detailed in the contributors guide

Core developers

Core developers are community members who have shown that they are dedicated to the continued development of the project through ongoing engagement with the community They have shown they can be trusted to maintain Scikit learn with care Being a core developer allows contributors to more easily carry on with their project related activities by giving them direct access to the project's repository and is represented as being an organization member on the scikitlearn GitHub organization Core developers are expected to review code contributions can merge approved pull requests can cast votes for and against merging a pullrequest and can be involved in deciding major changes to the API

New core developers can be nominated by any existing core developers Once they have been nominated there will be a vote by the current core developers V oting on new core developers is one of the few activities that takes place on the project's private management list While it is expected that most votes will be unanimous a twothirds majority of the cast votes is enough The vote needs to be open for at least 1 week

Core developers that have not contributed to the project commits or GitHub comments in the past 12 months will be asked if they want to become emeritus core developers and recant their commit and voting rights until they become active again The list of core developers active and emeritus with dates at which they became active is public on the scikitlearn website

Technical Committee

The Technical Committee TC members are core developers who have additional responsibilities to ensure the smooth running of the project TC members are expected to participate in strategic planning and approve changes to the governance model The purpose of the TC is to ensure a smooth progress from the bigpicture perspective Indeed changes that impact the full project require a synthetic analysis and a consensus that is both explicit and informed In cases that the core developer community which includes the TC members fails to reach such a consensus in the required time frame the TC is the entity to resolve the issue Membership of the TC is by nomination by a core developer A nomination will result in discussion which cannot take more than a month and then a vote by the core developers which will stay open for a week TC membership votes are subject to a twothird majority of all cast votes as well as a simple majority approval of all the current TC members TC members who do not actively engage with the TC duties are expected to resign

The initial Technical Committee of scikitlearn consists of Alexandre Gramfort Olivier Grisel Andreas Müller Joel Nothman Hanmin Qin Gaël Varoquaux and Roman Yurchak

1192 Decision Making Process

Decisions about the future of the project are made through discussion with all members of the community All non sensitive project management discussion takes place on the project contributors' mailing list and the issue tracker Occasionally sensitive discussion occurs on a private list

Scikitlearn uses a “consensus seeking” process for making decisions The group tries to find a resolution that has no open objections among core developers At any point during the discussion any coredeveloper can call for a vote which will conclude one month from the call for the vote Any vote must be backed by a SLEP If no option can gather two thirds of the votes cast the decision is escalated to the TC which in turn will use consensus seeking with the fallback option of a simple majority vote if no consensus can be found within a month This is what we hereafter may refer to as “the decision making process”

Decisions in addition to adding core developers and TC membership as above are made according to the following rules

•Minor Documentation changes such as typo fixes or addition correction of a sentence but no change of the scikitlearnorg landing page or the “about” page Requires 1 by a core developer no 1 by a core developer lazy consensus happens on the issue or pull request page Core developers are expected to give “reasonable time” to others to give their opinion on the pull request if they’re not confident others would agree

•Code changes and major documentation changes require 1 by two core developers no 1 by a core developer lazy consensus happens on the issue of pullrequest page

•Changes to the API principles and changes to dependencies or supported versions happen via a Enhance ment proposals SLEPs and follows the decisionmaking process outlined above

•Changes to the governance model use the same decision process outlined above

If a veto 1 vote is cast on a lazy consensus the proposer can appeal to the community and core developers and the change can be approved or rejected using the decision making procedure outlined above

1193 Enhancement proposals SLEPs

For all votes a proposal must have been made public and discussed before the vote Such proposal must be a consol idated document in the form of a ‘ScikitLearn Enhancement Proposal’ SLEP rather than a long discussion on an issue A SLEP must be submitted as a pullrequest to enhancement proposals using the SLEP template

CHAPTER
TWO
SCIKITLEARN TUTORIALS
21 An introduction to machine learning with scikitlearn
Section contents
In this section we introduce the machine learning vocabulary that we use throughout scikitlearn and give a simple learning example
211 Machine learning the problem setting
In general a learning problem considers a set of n samples of data and then tries to predict properties of unknown data If each sample is more than a single number and for instance a multidimensional entry aka multivariate data it is said to have several attributes or features
Learning problems fall into a few categories
• supervised learning in which the data comes with additional attributes that we want to predict Click here to go to the scikitlearn supervised learning pageThis problem can be either
–classification samples belong to two or more classes and we want to learn from already labeled data how to predict the class of unlabeled data An example of a classification problem would be handwritten digit recognition in which the aim is to assign each input vector to one of a finite number of discrete categories Another way to think of classification is as a discrete as opposed to continuous form of supervised learning where one has a limited number of categories and for each of the n samples provided one is to try to label them with the correct category or class
–regression if the desired output consists of one or more continuous variables then the task is called regression An example of a regression problem would be the prediction of the length of a salmon as a function of its age and weight
• unsupervised learning in which the training data consists of a set of input vectors x without any corresponding target values The goal in such problems may be to discover groups of similar examples within the data where it is called clustering or to determine the distribution of data within the input space known as density estima tion or to project the data from a highdimensional space down to two or three dimensions for the purpose of visualization Click here to go to the ScikitLearn unsupervised learning page

Training set and testing set
Machine learning is about learning some properties of a data set and then testing those properties against another data set A common practice in machine learning is to evaluate an algorithm by splitting a data set into two We call one of those sets the training set on which we learn some properties we call the other set the testing set on which we test the learned properties
212 Loading an example dataset
scikitlearn comes with a few standard datasets for instance the iris and digits datasets for classification and the boston house prices dataset for regression
In the following we start a Python interpreter from our shell and then load the iris anddigits datasets Our notational convention is that denotes the shell prompt while denotes the Python interpreter prompt
```
 python
 from sklearn import datasets
 iris  datasetsloadiris
 digits  datasetsloaddigits
```
A dataset is a dictionarylike object that holds all the data and some metadata about the data This data is stored in thedata member which is a nsamples nfeatures array In the case of supervised problem one or more response variables are stored in the target member More details on the different datasets can be found in the dedicated section
For instance in the case of the digits dataset digitsdata gives access to the features that can be used to classify the digits samples
```
printdigitsdata
 0 0 5  0 0 0
 0 0 0  10 0 0
 0 0 0  16 9 0

 0 0 1  6 0 0
 0 0 2  12 0 0
 0 0 10  12 1 0
```
anddigitstarget gives the ground truth for the digit dataset that is the number corresponding to each digit image that we are trying to learn
```
digitstarget
array0 1 2  8 9 8
```
Shape of the data arrays
The data is always a 2D array shape nsamples nfeatures although the original data may have had a different shape In the case of the digits each original sample is an image of shape 8 8 and can be accessed using
```
digitsimages0
array 0 0 5 13 9 1 0 0
 0 0 13 15 10 15 5 0
 0 3 15 2 0 11 8 0
 0 4 12 0 0 8 8 0
 0 5 8 0 0 9 8 0
 0 4 11 0 1 12 7 0
 0 2 14 5 10 12 0 0
 0 0 6 13 10 0 0 0
```

Thesimple example on this dataset illustrates how starting from the original problem one can shape the data for consumption in scikitlearn

Loading from external datasets

To load from an external dataset please refer to loading external datasets

213 Learning and predicting

In the case of the digits dataset the task is to predict given an image which digit it represents We are given samples of each of the 10 possible classes the digits zero through nine on which we fitan estimator to be able to predict the classes to which unseen samples belong

In scikitlearn an estimator for classification is a Python object that implements the methods fitX y and predictT

An example of an estimator is the class sklearnsvmSVC which implements support vector classification The estimator's constructor takes as arguments the model's parameters

For now we will consider the estimator as a black box

```
 from sklearn import svm
clf  svmSVCgamma0001 C100
```

Choosing the parameters of the model

In this example we set the value of gamma manually To find good values for these parameters we can use tools such as grid search andcross validation

Theclf for classifier estimator instance is first fitted to the model that is it must learn from the model This is done by passing our training set to the fit method For the training set we'll use all the images from our dataset except for the last image which we'll reserve for our predicting We select the training set with the 1 Python syntax which produces a new array that contains all but the last item from digitsdata

```
clffitdigitsdata1 digitstarget1
SVCC1000 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gamma0001 kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
```

Now you can predict new values In this case you'll predict using the last image from digitsdata By predicting you'll determine the image from the training set that best matches the last image

```
clfpredictdigitsdata1
array8
```

The corresponding image is
As you can see it is a challenging task after all the images
are of poor resolution Do you agree with the classifier
A complete example of this classification problem is available as an example that you can run and study Recognizing
handwritten digits
214 Model persistence
It is possible to save a model in scikitlearn by using Python’s builtin persistence model pickle
```
 from sklearn import svm
 from sklearn import datasets
clf  svmSVCgammascale
iris  datasetsloadiris
X y  irisdata iristarget
clffitX y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
 import pickle
s  pickledumpsclf
clf2  pickleloadss
clf2predictX01
array0
y0
0
```
In the specific case of scikitlearn it may be more interesting to use joblib’s replacement for pickle joblibdump
joblibload which is more efficient on big data but it can only pickle to the disk and not to a string
```
 from joblib import dump load
dumpclf filenamejoblib
```
Later you can reload the pickled model possibly in another Python process with
```
clf  loadfilenamejoblib
```
Notejoblibdump andjoblibload functions also accept filelike object instead of filenames More infor
mation on data persistence with Joblib is available here
Note that pickle has some security and maintainability issues Please refer to section Model persistence for more
detailed information about model persistence with scikitlearn

215 Conventions
scikitlearn estimators follow certain rules to make their behavior more predictive These are described in more detail in the Glossary of Common Terms and API Elements
Type casting
Unless otherwise specified input will be cast to float64
```
 import numpy as np
 from sklearn import randomprojection
rng  nprandomRandomState0
X  rngrand10 2000
X  nparrayX dtypefloat32
Xdtype
dtypefloat32
transformer  randomprojectionGaussianRandomProjection
Xnew  transformerfittransformX
Xnewdtype
dtypefloat64
```
In this example Xisfloat32 which is cast to float64 byfittransformX
Regression targets are cast to float64 and classification targets are maintained
```
 from sklearn import datasets
 from sklearnsvm import SVC
iris  datasetsloadiris
clf  SVCgammascale
clffitirisdata iristarget
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
listclfpredictirisdata3
0 0 0
clffitirisdata iristargetnamesiristarget
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
listclfpredictirisdata3
setosa setosa setosa
```
Here the first predict returns an integer array since iristarget an integer array was used in fit The secondpredict returns a string array since iristargetnames was for fitting
Refitting and updating parameters
Hyperparameters of an estimator can be updated after it has been constructed via the setparams method Calling fit more than once will overwrite what was learned by any previous fit

```
 import numpy as np
 from sklearndatasets import loadiris
 from sklearnsvm import SVC
X y  loadirisreturnXy True
clf  SVC
clfsetparamskernellinearfitX y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammaautodeprecated
kernellinear maxiter1 probabilityFalse randomstateNone
shrinkingTrue tol0001 verboseFalse
clfpredictX5
array0 0 0 0 0
clfsetparamskernelrbf gammascalefitX y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
clfpredictX5
array0 0 0 0 0
```
Here the default kernel rbf is first changed to linear viaSVCsetparams after the estimator has been constructed and changed back to rbf to refit the estimator and to make a second prediction

Multiclass vs multilabel fitting

When using multiclass classifiers the learning and prediction task that is performed is dependent on the format of the target data fit upon

```
 from sklearnsvm import SVC
 from sklearnmulticlass import OneVsRestClassifier
 from sklearnpreprocessing import LabelBinarizer
X  1 2 2 4 4 5 3 2 3 1
y  0 0 1 1 2
classif  OneVsRestClassifierestimatorSVCgammascale
 randomstate0
classiffitX ypredictX
array0 0 1 1 2
```
In the above case the classifier is fit on a 1d array of multiclass labels and the predict method therefore provides corresponding multiclass predictions It is also possible to fit upon a 2d array of binary label indicators

```
y  LabelBinarizerfittransformy
classiffitX ypredictX
array1 0 0
1 0 0
0 1 0
0 0 0
0 0 0
```
Here the classifier is fit on a 2d binary label representation of y using the LabelBinarizer In this case predict returns a 2d array representing the corresponding multilabel predictions

Note that the fourth and fifth instances returned all zeroes indicating that they matched none of the three labels fit upon With multilabel outputs it is similarly possible for an instance to be assigned multiple labels

```
 from sklearnpreprocessing import MultiLabelBinarizer
y  0 1 0 2 1 3 0 2 3 2 4
y  MultiLabelBinarizerfittransformy
classiffitX ypredictX
array1 1 0 0 0
1 0 1 0 0
0 1 0 1 0
1 0 1 0 0
1 0 1 0 0
```

In this case the classifier is fit upon instances each assigned multiple labels The MultiLabelBinarizer is used to binarize the 2d array of multilabels to fit upon As a result predict returns a 2d array with multiple predicted labels for each instance

22 A tutorial on statisticallearning for scientific data processing

Statistical learning

Machine learning is a technique with a growing importance as the size of the datasets experimental sciences are fac ing is rapidly growing Problems it tackles range from building a prediction function linking different observations to classifying observations or learning the structure in an unlabeled dataset

This tutorial will explore statistical learning the use of machine learning techniques with the goal of statistical inference drawing conclusions on the data at hand

Scikitlearn is a Python module integrating classic machine learning algorithms in the tightlyknit world of scientific Python packages NumPy SciPy matplotlib

221 Statistical learning the setting and the estimator object in scikitlearn

Datasets

Scikitlearn deals with learning information from one or more datasets that are represented as 2D arrays They can be understood as a list of multidimensional observations We say that the first axis of these arrays is the samples axis while the second is the features axis

A simple example shipped with scikitlearn iris dataset

```
 from sklearn import datasets
iris  datasetsloadiris
data  irisdata
datashape
150 4
```

It is made of 150 observations of irises each described by 4 features their sepal and petal length and width as detailed iniris DESCR

When the data is not initially in the nsamples nfeatures shape it needs to be preprocessed in order to
be used by scikitlearn
An example of reshaping data would be the digits dataset
The digits dataset is made of 1797 8x8 images of handwritten digits
digits datasetsloaddigits
digitsimagesshape
1797 8 8
 import matplotlibpyplot as plt
pltimshowdigitsimages1 cmappltcmgrayr
matplotlibimageAxesImage object at
To use this dataset with scikitlearn we transform each 8x8 image into a feature vector of length 64
data digitsimagesreshapedigitsimagesshape0 1
Estimators objects
Fitting data the main API implemented by scikitlearn is that of the estimator An estimator is any object that learns
from data it may be a classification regression or clustering algorithm or a transformer that extractsfilters useful
features from raw data
All estimator objects expose a fit method that takes a dataset usually a 2d array
estimatorfitdata
Estimator parameters All the parameters of an estimator can be set when it is instantiated or by modifying the
corresponding attribute
estimator Estimatorparam11 param22
estimatorparam1
1
Estimated parameters When data is fitted with an estimator parameters are estimated from the data at hand All the
estimated parameters are attributes of the estimator object ending by an underscore
estimatorestimatedparam

scikitlearn user guide Release 0213
222 Supervised learning predicting an output variable from highdimensional ob
servations
The problem solved in supervised learning
Supervised learning consists in learning the link between two datasets the observed data Xand an external variable
ythat we are trying to predict usually called “target” or “labels” Most often yis a 1D array of length nsamples
All supervised estimators in scikitlearn implement a fitX y method to fit the model and a predictX
method that given unlabeled observations X returns the predicted labels y
Vocabulary classification and regression
If the prediction task is to classify the observations in a set of finite labels in other words to “name” the objects
observed the task is said to be a classification task On the other hand if the goal is to predict a continuous target
variable it is said to be a regression task
When doing classification in scikitlearn yis a vector of integers or strings
Note See the Introduction to machine learning with scikitlearn Tutorial for a quick runthrough on the basic
machine learning vocabulary used within scikitlearn
Nearest neighbor and the curse of dimensionality
Classifying irises
22 A tutorial on statisticallearning for scientific data processing 159

The iris dataset is a
classification task consisting in identifying 3 different types of irises Setosa Versicolour and Virginica from their
petal and sepal length and width

```
 import numpy as np
 from sklearn import datasets
iris  datasetsloadiris
irisX  irisdata
irisy  iristarget
npuniqueirisy
array0 1 2
```

kNearest neighbors classifier
The simplest possible classifier is the nearest neighbor given a new observation Xtest find in the training set ie
the data used to train the estimator the observation with the closest feature vector Please see the Nearest Neighbors
section of the online Scikitlearn documentation for more information about this type of classifier
Training set and testing set
While experimenting with any learning algorithm it is important not to test the prediction of an estimator on the
data used to fit the estimator as this would not be evaluating the performance of the estimator on new data This is
why datasets are often split into train andtestdata

scikitlearn user guide Release 0213

The curse of dimensionality
For an estimator to be effective you need the distance between neighboring points to be less than some value which depends on the problem In one dimension this requires on average ~1points In the context of the above NN example if the data is described by just one feature with values ranging from 0 to 1 and with training observations then new data will be no further away than 1 Therefore the nearest neighbor decision rule will be efficient as soon as1is small compared to the scale of betweenclass feature variations
If the number of features is you now require ~1points Let’s say that we require 10 points in one dimension now10points are required in dimensions to pave the 01space As becomes large the number of training points required for a good estimator grows exponentially
For example if each point is just a single number 8 bytes then an effective NN estimator in a paltry ~20 dimensions would require more training data than the current estimated size of the entire internet ±1000 Exabytes or

so
This is called the curse of dimensionality and is a core problem that machine learning addresses
Linear model from regression to sparsity
Diabetes dataset
The diabetes dataset consists of 10 physiological variables age sex weight blood pressure measure on 442
patients and an indication of disease progression after one year
diabetes datasetsloaddiabetes

05855512036503 05830717085554 057058999437
```

Note Capturing in the fitted parameters noise that prevents the model to generalize to new data is called overfitting

The bias introduced by the ridge regression is called a regularization

Sparsity

Fitting only features 1 and 2

Note A representation of the full diabetes dataset would involve 11 dimensions 10 feature dimensions and one of the target variable It is hard to develop an intuition on such representation but it may be useful to keep in mind that it would be a fairly empty space

We can see that although feature 2 has a strong coefficient on the full model it conveys little information on ywhen considered with feature 1

To improve the conditioning of the problem ie mitigating the The curse of dimensionality it would be interesting to select only the informative features and set noninformative ones like feature 2 to 0 Ridge regression will decrease their contribution but not set them to zero Another penalization approach called Lasso least absolute shrinkage and selection operator can set some coefficients to zero Such methods are called sparse method and sparsity can be seen as an application of Occam’s razor prefer simpler models

```

Different algorithms for the same problem
Different algorithms can be used to solve the same mathematical problem For instance the Lasso object in scikit
learn solves the lasso regression problem using a coordinate descent method that is efficient on large datasets
However scikitlearn also provides the LassoLars object using the LARS algorithm which is very efficient for
problems in which the weight vector estimated is very sparse ie problems with very few observations
Classification
For classification as in the labeling iris task linear regression is not
the right approach as it will give too much weight to data far from the decision frontier A linear approach is to fit a
sigmoid function or logistic function

Support vector machines SVMs
Linear SVMs
Support Vector Machines belong to the discriminant model family they try to find a combination of samples to build a plane maximizing the margin between the two classes Regularization is set by the Cparameter a small value for C means the margin is calculated using many or all of the observations around the separating line more regularization a large value for Cmeans the margin is calculated on observations close to the separating line less regularization
Unregularized SVM Regularized SVM default

Example
•Plot different SVM classifiers in the iris dataset
SVMs can be used in regression – SVR Support Vector Regression– or in classification – SVC Support Vector Clas
sification

Train 0 1 4 5 6 7 8 9 test 2 3
Train 0 1 2 3 6 7 8 9 test 4 5
Train 0 1 2 3 4 5 8 9 test 6 7
Train 0 1 2 3 4 5 6 7 test 8 9
The crossvalidation can then be performed easily
```
svcfitXdigitstrain ydigitstrainscoreXdigitstest ydigitstest
 for train test inkfoldsplitXdigits
```
0963 0922 0963 0963 0930
The crossvalidation score can be directly calculated using the crossvalscore helper Given an estimator the crossvalidation object and the input dataset the crossvalscore splits the data repeatedly into a training and a testing set trains the estimator using the training set and computes the scores based on the testing set for each iteration of crossvalidation
By default the estimator’s score method is used to compute the individual scores
Refer the metrics module to learn more on the available scoring methods
```
crossvalscoresvc Xdigits ydigits cvkfold njobs1
```
array096388889 092222222 09637883 09637883 093036212
njobs1 means that the computation will be dispatched on all the CPUs of the computer
Alternatively the scoring argument can be provided to specify an alternative scoring method
```

Leave P observations out Generates traintest indices based on predefined splits
Exercise
On the
digits dataset plot the crossvalidation score of a SVC estimator with an linear kernel as a function of parameter C
use a logarithmic grid of points from 1 to 10
import numpy as np
from sklearnmodelselection import crossvalscore
from sklearn import datasets svm
digits datasetsloaddigits
X digitsdata
y digitstarget
svc svmSVCkernellinear
Cs nplogspace10 0 10

Solution Crossvalidation on Digits Dataset Exercise
Gridsearch and crossvalidated estimators
Gridsearch
scikitlearn provides an object that given data computes the score during the fit of an estimator on a parameter grid and chooses the parameters to maximize the crossvalidation score This object takes an estimator during the construction and exposes an estimator API

```
 from sklearnmodelselection import GridSearchCV crossvalscore
Cs  nplogspace6 1 10
clf  GridSearchCVestimatorsvc paramgriddictCCs
 njobs1
clffitXdigits1000 ydigits1000
GridSearchCVcvNone
clfbestscore
0925
clfbestestimatorC
00077
 Prediction performance on test set is not as good as on train set
clfscoreXdigits1000 ydigits1000
0943
```

By default the GridSearchCV uses a 3fold crossvalidation However if it detects that a classifier is passed rather than a regressor it uses a stratified 3fold The default will change to a 5fold crossvalidation in version 022
Nested crossvalidation

```
crossvalscoreclf Xdigits ydigits
array0938 0963 0944
```

Two crossvalidation loops are performed in parallel one by the GridSearchCV estimator to set gamma and the other one by crossvalscore to measure the prediction performance of the estimator The resulting scores are unbiased estimates of the prediction score on new data
Warning You cannot nest objects with parallel computing njobs different than 1
Crossvalidated estimators
Crossvalidation to set a parameter can be done more efficiently on an algorithmbyalgorithm basis This is why for certain estimators scikitlearn exposes Crossvalidation evaluating estimator performance estimators that set their parameter automatically by crossvalidation

```
 from sklearn import linearmodel datasets
lasso  linearmodelLassoCVcv3
diabetes  datasetsloaddiabetes
Xdiabetes  diabetesdata
ydiabetes  diabetestarget

X diabetesdata150
Solution Crossvalidation on diabetes Dataset Exercise
224 Unsupervised learning seeking representations of the data
Clustering grouping observations together
The problem solved in clustering
Given the iris dataset if we knew that there were 3 types of iris but did not have access to a taxonomist to label
them we could try a clustering task split the observations into wellseparated group called clusters

scikitlearn user guide Release 0213
Kmeans clustering
Note that there exist a lot of different clustering criteria and associated algorithms The simplest clustering algorithm isKmeans
```
 from sklearn import cluster datasets
iris  datasetsloadiris
Xiris  irisdata
yiris  iristarget
kmeans  clusterKMeansnclusters3
kmeansfitXiris
KMeansalgorithmauto copyxTrue initkmeans
printkmeanslabels10
1 1 1 1 1 0 0 0 0 0 2 2 2 2 2
printyiris10
0 0 0 0 0 1 1 1 1 1 2 2 2 2 2
```
Warning There is absolutely no guarantee of recovering a ground truth First choosing the right number of clusters is hard Second the algorithm is sensitive to initialization and can fall into local minima although scikit learn employs several tricks to mitigate this issue
Bad initialization 8 clusters Ground truth
Don’t overinterpret clustering results
Application example vector quantization
Clustering in general and KMeans in particular can be seen as a way of choosing a small number of exemplars to compress the information The problem is sometimes known as vector quantization For instance this can be used

Hierarchical agglomerative clustering Ward
AHierarchical clustering method is a type of cluster analysis that aims to build a hierarchy of clusters In general the various approaches of this technique are either
•Agglomerative bottomup approaches each observation starts in its own cluster and clusters are iteratively merged in such a way to minimize a linkage criterion This approach is particularly interesting when the clus ters of interest are made of only a few observations When the number of clusters is large it is much more computationally efficient than kmeans
•Divisive topdown approaches all observations start in one cluster which is iteratively split as one moves down the hierarchy For estimating large numbers of clusters this approach is both slow due to all observations starting as one cluster which it splits recursively and statistically illposed
Connectivityconstrained clustering
With agglomerative clustering it is possible to specify which samples can be clustered together by giving a connec tivity graph Graphs in scikitlearn are represented by their adjacency matrix Often a sparse matrix is used This can be useful for instance to retrieve connected regions sometimes also referred to as connected components when

transform andinversetransform methods
Some estimators expose a transform method for instance to reduce the dimensionality of the dataset
Decompositions from a signal to components and loadings
Components and loadings
If X is our multivariate data then the problem that we are trying to solve is to rewrite it on a different observational basis we want to learn loadings L and a set of components C such that X L C Different criteria exist to choose the components
Principal component analysis PCA
Principal component analysis PCA selects the successive components that explain the maximum variance in the signal

The point cloud spanned by the observations above is very flat in one direction one of the three univariate features
can almost be exactly computed using the other two PCA finds the directions in which the data is not flat
When used to transform data PCA can reduce the dimensionality of the data by projecting on a principal subspace
```
 Create a signal with only 2 useful dimensions

23 Working With Text Data
The goal of this guide is to explore some of the main scikitlearn tools on a single practical task analyzing a
collection of text documents newsgroups posts on twenty different topics
In this section we will see how to
• load the file contents and the categories
• extract feature vectors suitable for machine learning
• train a linear model to perform categorization
• use a grid search strategy to find a good configuration of both the feature extraction components and the classifier
231 Tutorial setup
To get started with this tutorial you must first install scikitlearn and all of its required dependencies
Please refer to the installation instructions page for more information and for systemspecific instructions
The source of this tutorial can be found within your scikitlearn folder
scikitlearndoctutorialtextanalytics
The source can also be found on Github
The tutorial folder should contain the following subfolders
•rst files the source of the tutorial document written with sphinx
•data folder to put the datasets used during the tutorial
•skeletons sample incomplete scripts for the exercises
•solutions solutions of the exercises
You can already copy the skeletons into a new folder somewhere on your harddrive named
sklearntutworkspace where you will edit your own files for the exercises while keeping the original
skeletons intact
```
 cp r skeletons workdirectorysklearntutworkspace
```

Machine learning algorithms need data Go to each TUTORIALHOMEdata subfolder and run the
fetchdatapy script from there after having read them first
For instance
```
 cd TUTORIALHOMEdatalanguages
 less fetchdatapy
 python fetchdatapy
```
232 Loading the 20 newsgroups dataset
The dataset is called “Twenty Newsgroups” Here is the official description quoted from the website
The 20 Newsgroups data set is a collection of approximately 20000 newsgroup documents partitioned
nearly evenly across 20 different newsgroups To the best of our knowledge it was originally collected
by Ken Lang probably for his paper “Newsweeder Learning to filter netnews” though he does not explic
itly mention this collection The 20 newsgroups collection has become a popular data set for experiments
in text applications of machine learning techniques such as text classification and text clustering
In the following we will use the builtin dataset loader for 20 newsgroups from scikitlearn Alternatively it is possible
to download the dataset manually from the website and use the sklearndatasetsloadfiles function by
pointing it to the 20newsbydatetrain subfolder of the uncompressed archive folder
In order to get faster execution times for this first example we will work on a partial dataset with only 4 categories out
of the 20 available in the dataset
```
categories  altatheism socreligionchristian
 compgraphics scimed
```
We can now load the list of files matching those categories as follows
```
 from sklearndatasets import fetch20newsgroups
twentytrain  fetch20newsgroupssubsettrain
 categoriescategories shuffle True randomstate42
```
The returned dataset is a scikitlearn “bunch” a simple holder object with fields that can be both accessed
as pythondict keys orobject attributes for convenience for instance the targetnames holds the list of the
requested category names
```
twentytraintargetnames
```
```
altatheism compgraphics scimed socreligionchristian
```
The files themselves are loaded in memory in the data attribute For reference the filenames are also available
```

scikitlearn user guide Release 0213
Supervised learning algorithms will require a category label for each document in the training set In this case the category is the name of the newsgroup which also happens to be the name of the folder holding the individual documents
For speed and space efficiency reasons scikitlearn loads the target attribute as an array of integers that corresponds to the index of the category name in the targetnames list The category integer id of each sample is stored in thetarget attribute

You might have noticed that the samples were shuffled randomly when we called fetch20newsgroups
shuffleTrue randomstate42 this is useful if you wish to select only a subset of samples to quickly
train a model and get a first idea of the results before retraining on the complete dataset later
233 Extracting features from text files
In order to perform machine learning on text documents we first need to turn the text content into numerical feature vectors
Bags of words
The most intuitive way to do so is to use a bags of words representation
1 Assign a fixed integer id to each word occurring in any document of the training set for instance by building a dictionary from words to integer indices
2 For each document i count the number of occurrences of each word wand store it in Xi j as the value of featurejwherejis the index of word win the dictionary
The bags of words representation implies that nfeatures is the number of distinct words in the corpus this number is typically larger than 100000
Ifnsamples 10000 storingXas a NumPy array of type float32 would require 10000 x 100000 x 4 bytes 4GB in RAM which is barely manageable on today’s computers
Fortunately most values in X will be zeros since for a given document less than a few thousand distinct words will be used For this reason we say that bags of words are typically highdimensional sparse datasets We can save a lot of memory by only storing the nonzero parts of the feature vectors in memory

scipysparse matrices are data structures that do exactly this and scikitlearn has builtin support for these structures

Tokenizing text with scikitlearn

Text preprocessing tokenizing and filtering of stopwords are all included in CountVectorizer which builds a dictionary of features and transforms documents to feature vectors

```
from sklearnfeatureextractiontext import CountVectorizer
countvect CountVectorizer
Xtraincounts countvectfittransformtwentytraindata
Xtraincountsshape
```

```
2257 35788
```

CountVectorizer supports counts of Ngrams of words or consecutive characters Once fitted the vectorizer has built a dictionary of feature indices

```
countvectvocabularygetualgorithm
```

```
4690
```

The index value of a word in the vocabulary is linked to its frequency in the whole training corpus

From occurrences to frequencies

Occurrence count is a good start but there is an issue longer documents will have higher average count values than shorter documents even though they might talk about the same topics

To avoid these potential discrepancies it suffices to divide the number of occurrences of each word in a document by the total number of words in the document these new features are called tffor Term Frequencies

Another refinement on top of tf is to downscale weights for words that occur in many documents in the corpus and are therefore less informative than those that occur only in a smaller portion of the corpus

This downscaling is called tf–idf for “Term Frequency times Inverse Document Frequency”

Both tfandtf–idf can be computed as follows using TfidfTransformer

```
from sklearnfeatureextractiontext import TfidfTransformer
tftransformer TfidfTransformeruseidf FalsefitXtraincounts
Xtraintf tftransformertransformXtraincounts
Xtraintfshape
```

```
2257 35788
```

In the above examplecode we firstly use the fit method to fit our estimator to the data and secondly the transform method to transform our countmatrix to a tfidf representation These two steps can be com bined to achieve the same end result faster by skipping redundant processing This is done through using the fittransform method as shown below and as mentioned in the note in the previous section

```
tfidftransformer TfidfTransformer
Xtraintfidf tfidftransformerfittransformXtraincounts
Xtraintfidfshape
```

```
2257 35788
```

234 Training a classifier
Now that we have our features we can train a classifier to try to predict the category of a post Let’s start with a naïve Bayes classifier which provides a nice baseline for this task scikitlearn includes several variants of this classifier the one most suitable for word counts is the multinomial variant

```
 from sklearnnaivebayes import MultinomialNB
clf  MultinomialNBfitXtraintfidf twentytraintarget
```

To try to predict the outcome on a new document we need to extract the features using almost the same feature extracting chain as before The difference is that we call transform instead offittransform on the transformers since they have already been fit to the training set

```
docsnew  God is love OpenGL on the GPU is fast
Xnewcounts  countvecttransformdocsnew
Xnewtfidf  tfidftransformertransformXnewcounts
predicted  clfpredictXnewtfidf
 for doc category inzipdocsnew predicted
 printrs  doc twentytraintargetnamescategory

God is love  socreligionchristian
OpenGL on the GPU is fast  compgraphics
```

235 Building a pipeline
In order to make the vectorizer transformer classifier easier to work with scikitlearn provides a Pipeline class that behaves like a compound classifier

```
 from sklearnpipeline import Pipeline
textclf  Pipeline
 vect CountVectorizer
 tfidf TfidfTransformer
 clf MultinomialNB
```

The names vect tfidf andclf classifier are arbitrary We will use them to perform grid search for suitable hyperparameters below We can now train the model with a single command

```
textclffittwentytraindata twentytraintarget
Pipeline
```

236 Evaluation of the performance on the test set
Evaluating the predictive accuracy of the model is equally easy

```
 import numpy as np
twentytest  fetch20newsgroupssubsettest
 categoriescategories shuffle True randomstate42
docstest  twentytestdata
predicted  textclfpredictdocstest
npmeanpredicted  twentytesttarget
08348
```

We achieved 835 accuracy Let’s see if we can do better with a linear support vector machine SVM which is widely regarded as one of the best text classification algorithms although it’s also a bit slower than naïve Bayes We can change the learner by simply plugging a different classifier object into our pipeline

```
 from sklearnlinearmodel import SGDClassifier
textclf  Pipeline
 vect CountVectorizer
 tfidf TfidfTransformer
 clf SGDClassifierlosshinge penaltyl2
 alpha1e3 randomstate42
 maxiter5 tol None

textclffittwentytraindata twentytraintarget
Pipeline
predicted  textclfpredictdocstest
npmeanpredicted  twentytesttarget
09101
```

We achieved 913 accuracy using the SVM scikitlearn provides further utilities for more detailed perfor mance analysis of the results

```
 from sklearn import metrics

As expected the confusion matrix shows that posts from the newsgroups on atheism and Christianity are more often confused for one another than with computer graphics

237 Parameter tuning using grid search

We’ve already encountered some parameters such as useidf in theTfidfTransformer Classifiers tend to have many parameters as well eg MultinomialNB includes a smoothing parameter alpha andSGDClassifier has a penalty parameter alpha and configurable loss and penalty terms in the objective function see the module documentation or use the Python help function to get a description of these

Instead of tweaking the parameters of the various components of the chain it is possible to run an exhaustive search of the best parameters on a grid of possible values We try out all classifiers on either words or bigrams with or without idf and with a penalty parameter of either 001 or 0001 for the linear SVM

scikitlearn user guide Release 0213
```
 from sklearnmodelselection import GridSearchCV
parameters
 vectngramrange 1 1 1 2
 tfidfuseidf  TrueFalse
 clfalpha 1e2 1e3
```

Obviously such an exhaustive search can be expensive If we have multiple CPU cores at our disposal we can tell the grid searcher to try these eight parameter combinations in parallel with the njobs parameter If we give this parameter a value of 1 grid search will detect how many cores are installed and use them all
```
gsclf  GridSearchCVtextclf parameters cv5 iid False njobs1
```
The grid search instance behaves like a normal scikitlearn model Let's perform the search on a smaller subset of the training data to speed up the computation
```

```
gsclfbestscore
09
 for paramname insortedparameterskeys
 printsr  paramname gsclfbestparamsparamname

clfalpha 0001
tfidfuseidf True
vectngramrange 1 1
```
A more detailed summary of the search is available at gsclfcvresults
Thecvresults parameter can be easily imported into pandas as a DataFrame for further inspection

Exercises

To do the exercises copy the content of the 'skeletons' folder as a new folder named 'workspace'
```
 cp r skeletons workspace
```
You can then edit the content of the workspace without fear of losing the original exercise instructions
Then fire an ipython shell and run the workinprogress script with
```
1 run workspaceexerciseXXscriptpy arg1 arg2 arg3
```
If an exception is triggered use debug to fireup a post mortem ipdb session
Refine the implementation and iterate until the exercise is solved
For each exercise the skeleton file provides all the necessary import statements boilerplate code to load the data and sample code to evaluate the predictive accuracy of the model

238 Exercise 1 Language identification
• Write a text classification pipeline using a custom preprocessor and CharNGramAnalyzer using data from Wikipedia articles as training set
• Evaluate the performance on some held out test set
ipython command line
run workspaceexercise01languagetrainmodelpy datalanguagesparagraphs
239 Exercise 2 Sentiment Analysis on movie reviews
• Write a text classification pipeline to classify movie reviews as either positive or negative
• Find a good set of parameters using grid search
• Evaluate the performance on a held out test set
ipython command line
run workspaceexercise02sentimentpy datamoviereviewstxtsentoken
2310 Exercise 3 CLI text classification utility
Using the results of the previous exercises and the cPickle module of the standard library write a command line utility that detects the language of some text provided on stdin and estimate the polarity positive or negative if the text is written in English
Bonus point if the utility is able to give a confidence level for its predictions
2311 Where to from here
Here are a few suggestions to help further your scikitlearn intuition upon the completion of this tutorial
• Try playing around with the analyzer andtoken normalisation underCountVectorizer
• If you don’t have labels try using Clustering on your problem
• If you have multiple labels per document eg categories have a look at the Multiclass and multilabel section
• Try using Truncated SVD for latent semantic analysis
• Have a look at using Outofcore Classification to learn from data that would not fit into the computer main memory
• Have a look at the Hashing Vectorizer as a memory efficient alternative to CountVectorizer
24 Choosing the right estimator
Often the hardest part of solving a machine learning problem can be finding the right estimator for the job
Different estimators are better suited for different types of data and different problems
The flowchart below is designed to give users a bit of a rough guide on how to approach problems with regard to which estimators to try on your data

scikitlearn user guide Release 0213
Click on any estimator in the chart below to see its documentation
25 External Resources Videos and Talks
For written tutorials see the Tutorial section of the documentation
251 New to Scientific Python
For those that are still new to the scientific Python ecosystem we highly recommend the Python Scientific Lecture Notes This will help you find your footing a bit and will definitely improve your scikitlearn experience A basic understanding of NumPy arrays is recommended to make the most of scikitlearn
252 External Tutorials
There are several online tutorials available which are geared toward specific subject areas
• Machine Learning for NeuroImaging in Python
• Machine Learning for Astronomical Data Analysis
253 Videos
• An introduction to scikitlearn Part I and Part II at Scipy 2013 by Gael Varoquaux Jake Vanderplas and Olivier Grisel Notebooks on github
• Introduction to scikitlearn by Gael Varoquaux at ICML 2010
A three minute video from a very early stage of scikitlearn explaining the basic idea and approach we are following
• Introduction to statistical learning with scikitlearn by Gael Varoquaux at SciPy 2011
An extensive tutorial consisting of four sessions of one hour The tutorial covers the basics of ma chine learning many algorithms and how to apply them using scikitlearn The material correspond ing is now in the scikitlearn documentation section A tutorial on statisticallearning for scientific data processing
• Statistical Learning for Text Classification with scikitlearn and NLTK and slides by Olivier Grisel at PyCon 2011
Thirty minute introduction to text classification Explains how to use NLTK and scikitlearn to solve realworld text classification tasks and compares against cloudbased solutions
• Introduction to Interactive Predictive Analytics in Python with scikitlearn by Olivier Grisel at PyCon 2012
3hours long introduction to prediction tasks using scikitlearn
• scikitlearn Machine Learning in Python by Jake Vanderplas at the 2012 PyData workshop at Google
Interactive demonstration of some scikitlearn features 75 minutes
• scikitlearn tutorial by Jake Vanderplas at PyData NYC 2012
Presentation using the online tutorial 45 minutes

Note Doctest Mode
The codeexamples in the above tutorials are written in a pythonconsole format If you wish to easily execute these examples in IPython use
doctestmode
in the IPythonconsole You can then simply copy and paste the examples directly into IPython without having to worry about removing the manually

CHAPTER
THREE
USER GUIDE
31 Supervised learning
311 Generalized Linear Models
The following are a set of methods intended for regression in which the target value is expected to be a linear combi
nation of the features In mathematical notation if □is the predicted value
□□ □ □0□1□1□□□□
Across the module we designate the vector □ □1 □ □ascoef and□0asintercept
To perform classification with generalized linear models see Logistic regression
Ordinary Least Squares
LinearRegression fits a linear model with coefficients □ □1 □ □to minimize the residual sum of squares
between the observed targets in the dataset and the targets predicted by the linear approximation Mathematically it
solves a problem of the form
min
□□□−□2
2
LinearRegression will take in its fit method arrays X y and will store the coefficients □of the linear model
in itscoef member

```
 from sklearn import linearmodel
reg  linearmodelLinearRegression
regfit0 0 1 1 2 2 0 1 2

LinearRegressioncopyXTrue fitinterceptTrue njobsNone
normalizeFalse
regcoef
array05 05
```
The coefficient estimates for Ordinary Least Squares rely on the independence of the features When features are correlated and the columns of the design matrix □have an approximate linear dependence the design matrix becomes close to singular and as a result the leastsquares estimate becomes highly sensitive to random errors in the observed target producing a large variance This situation of multicollinearity can arise for example when data are collected without an experimental design

Examples

•Linear Regression Example

Ordinary Least Squares Complexity

The least squares solution is computed using the singular value decomposition of X If X is a matrix of shape nsamples nfeatures this method has a cost of □□samples □2
features assuming that □samples≥□features

Ridge Regression

Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients The ridge coefficients minimize a penalized residual sum of squares

min
□□□−□2
2□□2
2

The complexity parameter □≥0controls the amount of shrinkage the larger the value of □ the greater the amount of shrinkage and thus the coefficients become more robust to collinearity

As with other linear models Ridge will take in its fit method arrays X y and will store the coefficients □of the linear model in its coef member

```
 from sklearn import linearmodel
reg  linearmodelRidgealpha5
regfit0 0 0 0 1 1 0 1 1
Ridgealpha05 copyXTrue fitinterceptTrue maxiterNone
normalizeFalse randomstateNone solverauto tol0001
regcoef
array034545455 034545455
regintercept
013636
```
Examples
•Plot Ridge coefficients as a function of the regularization
•Classification of text documents using sparse features
Ridge Complexity
This method has the same order of complexity as Ordinary Least Squares
Setting the regularization parameter generalized CrossValidation
RidgeCV implements ridge regression with builtin crossvalidation of the alpha parameter The object works in the same way as GridSearchCV except that it defaults to Generalized CrossValidation GCV an efficient form of leaveoneout crossvalidation
```
 import numpy as np
 from sklearn import linearmodel
reg  linearmodelRidgeCValphasnplogspace6 6 13
regfit0 0 0 0 1 1 0 1 1
RidgeCValphasarray1e06 1e05 1e04 1e03 1e02 1e01 1e00 1e01
1e02 1e03 1e04 1e05 1e06
cvNone fitinterceptTrue gcvmodeNone normalizeFalse
scoringNone storecvvaluesFalse
regalpha
001
```
Specifying the value of the cvattribute will trigger the use of crossvalidation with GridSearchCV for example cv10 for 10fold crossvalidation rather than Generalized CrossValidation

• “Notes on Regularized Least Squares” Rifkin Lippert technical report course slides
Lasso
TheLasso is a linear model that estimates sparse coefficients It is useful in some contexts due to its tendency to prefer solutions with fewer nonzero coefficients effectively reducing the number of features upon which the given solution is dependent For this reason Lasso and its variants are fundamental to the field of compressed sensing

Under certain conditions it can recover the exact set of nonzero coefficients see Compressive sensing tomography reconstruction with L1 prior Lasso
Mathematically it consists of a linear model with an added regularization term The objective function to minimize is
min
□1
2□samples□□−□2
2□□1
The lasso estimate thus solves the minimization of the leastsquares penalty with □□1added where □is a constant and□1is the ℓ1norm of the coefficient vector
The implementation in the class Lasso uses coordinate descent as the algorithm to fit the coefficients See Least Angle Regression for another implementation
```
 from sklearn import linearmodel
reg  linearmodelLassoalpha01
regfit0 0 1 1 0 1
Lassoalpha01 copyXTrue fitinterceptTrue maxiter1000
normalizeFalse positiveFalse precomputeFalse randomstateNone
selectioncyclic tol00001 warmstartFalse
regpredict1 1
array08
```
The function lassopath is useful for lowerlevel tasks as it computes the coefficients along the full path of possible values
Examples
•Lasso and Elastic Net for Sparse Signals
•Compressive sensing tomography reconstruction with L1 prior Lasso
Note Feature selection with Lasso
As the Lasso regression yields sparse models it can thus be used to perform feature selection as detailed in L1based feature selection
The following two references explain the iterations used in the coordinate descent solver of scikitlearn as well as the duality gap computation used for convergence control
References
• “Regularization Path For Generalized linear Models by Coordinate Descent” Friedman Hastie Tibshirani J Stat Softw 2010 Paper
• “An InteriorPoint Method for LargeScale L1Regularized Least Squares” S J Kim K Koh M Lustig S Boyd and D Gorinevsky in IEEE Journal of Selected Topics in Signal Processing 2007 Paper
Setting regularization parameter
Thealpha parameter controls the degree of sparsity of the estimated coefficients

Using crossvalidation
scikitlearn exposes objects that set the Lasso alpha parameter by crossvalidation LassoCV andLassoLarsCV
LassoLarsCV is based on the Least Angle Regression algorithm explained below
For highdimensional datasets with many collinear features LassoCV is most often preferable However
LassoLarsCV has the advantage of exploring more relevant values of alpha parameter and if the number of
samples is very small compared to the number of features it is often faster than LassoCV
Informationcriteria based model selection
Alternatively the estimator LassoLarsIC proposes to use the Akaike information criterion AIC and the Bayes
Information criterion BIC It is a computationally cheaper alternative to find the optimal value of alpha as the regu
larization path is computed only once instead of k1 times when using kfold crossvalidation However such criteria
needs a proper estimation of the degrees of freedom of the solution are derived for large samples asymptotic results
and assume the model is correct ie that the data are actually generated by this model They also tend to break when
the problem is badly conditioned more features than samples
Examples
•Lasso model selection CrossValidation AIC BIC

Comparison with the regularization parameter of SVM
The equivalence between alpha and the regularization parameter of SVM Cis given by alpha 1 C or alpha 1 nsamples C depending on the estimator and the exact objective function optimized by the model
Multitask Lasso
TheMultiTaskLasso is a linear model that estimates sparse coefficients for multiple regression problems jointly yis a 2D array of shape nsamples ntasks The constraint is that the selected features are the same for all the regression problems also called tasks
The following figure compares the location of the nonzero entries in the coefficient matrix W obtained with a simple Lasso or a MultiTaskLasso The Lasso estimates yield scattered nonzeros while the nonzeros of the MultiTaskLasso are full columns
Fitting a timeseries model imposing that any active feature be active at all times
Examples
•Joint feature selection with multitask Lasso
Mathematically it consists of a linear model trained with a mixed ℓ1ℓ2norm for regularization The objective function

to minimize is
min
□1
2□samples□□−□2
Fro□□21
where Fro indicates the Frobenius norm
□Fro√∑
□□□2
□□
and$\ell 1\ell 2$reads
□21∑
□√∑
□□2
□□
The implementation in the class MultiTaskLasso uses coordinate descent as the algorithm to fit the coefficients
ElasticNet
ElasticNet is a linear regression model trained with both $\ell 1$and$\ell 2$norm regularization of the coefficients This combination allows for learning a sparse model where few of the weights are nonzero like Lasso while still maintaining the regularization properties of Ridge We control the convex combination of $\ell 1$and$\ell 2$using thel1ratio parameter
Elasticnet is useful when there are multiple features which are correlated with one another Lasso is likely to pick one of these at random while elasticnet is likely to pick both
A practical advantage of tradingoff between Lasso and Ridge is that it allows ElasticNet to inherit some of Ridge's stability under rotation
The objective function to minimize is in this case
min
□1
2□samples□□−□2
2□□□1□1−□
2□2
2
The classElasticNetCV can be used to set the parameters alpha □ andl1ratio □ by crossvalidation

Examples
•Lasso and Elastic Net for Sparse Signals
•Lasso and Elastic Net
The following two references explain the iterations used in the coordinate descent solver of scikitlearn as well as the duality gap computation used for convergence control

The classMultiTaskElasticNetCV can be used to set the parameters alpha □ andl1ratio □ by cross validation
Least Angle Regression
Leastangle regression LARS is a regression algorithm for highdimensional data developed by Bradley Efron Trevor Hastie Iain Johnstone and Robert Tibshirani LARS is similar to forward stepwise regression At each step it finds the feature most correlated with the target When there are multiple features having equal correlation instead of continuing along the same feature it proceeds in a direction equiangular between the features
The advantages of LARS are
• It is numerically efficient in contexts where the number of features is significantly greater than the number of samples
• It is computationally just as fast as forward selection and has the same order of complexity as ordinary least squares
• It produces a full piecewise linear solution path which is useful in crossvalidation or similar attempts to tune the model
• If two features are almost equally correlated with the target then their coefficients should increase at approxi mately the same rate The algorithm thus behaves as intuition would expect and also is more stable

• It is easily modified to produce solutions for other estimators like the Lasso
The disadvantages of the LARS method include
• Because LARS is based upon an iterative refitting of the residuals it would appear to be especially sensitive to the effects of noise This problem is discussed in detail by Weisberg in the discussion section of the Efron et al 2004 Annals of Statistics article
The LARS model can be used using estimator Lars or its lowlevel implementation larspath or larspathgram
LARS Lasso
LassoLars is a lasso model implemented using the LARS algorithm and unlike the implementation based on coordinate descent this yields the exact solution which is piecewise linear as a function of the norm of its coefficients
```
 from sklearn import linearmodel
reg  linearmodelLassoLarsalpha1
regfit0 0 1 1 0 1
LassoLarsalpha01 copyXTrue eps fitinterceptTrue
fitpathTrue maxiter500 normalizeTrue positiveFalse
precomputeauto verboseFalse
regcoef
array0717157 0
```
Examples
•Lasso path using LARS
The Lars algorithm provides the full path of the coefficients along the regularization parameter almost for free thus a common operation is to retrieve the path with one of the functions larspath orlarspathgram
Mathematical formulation
The algorithm is similar to forward stepwise regression but instead of including features at each step the estimated coefficients are increased in a direction equiangular to each one’s correlations with the residual

Instead of giving a vector result the LARS solution consists of a curve denoting the solution for each value of the ℓ1norm of the parameter vector The full coefficients path is stored in the array coefpath which has size nfeatures maxfeatures1 The first column is always zero

Orthogonal Matching Pursuit OMP

OrthogonalMatchingPursuit andorthogonalmp implements the OMP algorithm for approximating the fit of a linear model with constraints imposed on the number of nonzero coefficients ie the ℓ0pseudonorm

Being a forward feature selection method like Least Angle Regression orthogonal matching pursuit can approximate the optimum solution vector with a fixed number of nonzero elements

arg min

□□−□□2

2subject to□0≤□nonzerocoefs

Alternatively orthogonal matching pursuit can target a specific error instead of a specific number of nonzero coeffi cients This can be expressed as

arg min

□□0subject to□−□□2

2≤tol

OMP is based on a greedy algorithm that includes at each step the atom most highly correlated with the current residual It is similar to the simpler matching pursuit MP method but better in that at each iteration the residual is recomputed using an orthogonal projection on the space of the previously chosen dictionary elements

Examples

•Orthogonal Matching Pursuit

Bayesian Regression

Bayesian regression techniques can be used to include regularization parameters in the estimation procedure the regularization parameter is not set in a hard sense but tuned to the data at hand

This can be done by introducing uninformative priors over the hyper parameters of the model The ℓ2regularization used in Ridge Regression is equivalent to finding a maximum a posteriori estimation under a Gaussian prior over the coefficients □with precision □−1 Instead of setting lambda manually it is possible to treat it as a random variable to be estimated from the data

To obtain a fully probabilistic model the output □is assumed to be Gaussian distributed around □□

□□□ □ □ □□□□ □

where □is again treated as a random variable that is to be estimated from the data
The advantages of Bayesian Regression are
• It adapts to the data at hand
• It can be used to include regularization parameters in the estimation procedure
The disadvantages of Bayesian regression include
• Inference of the model can be time consuming
References
• A good introduction to Bayesian methods is given in C Bishop Pattern Recognition and Machine learning
• Original Algorithm is detailed in the book Bayesian learning for neural networks by Rad
ford M Neal
Bayesian Ridge Regression
BayesianRidge estimates a probabilistic model of the regression problem as described above The prior for the coefficient □is given by a spherical Gaussian
□□□ □□0 □−1I□
The priors over □and□are chosen to be gamma distributions the conjugate prior for the precision of the Gaussian
The resulting model is called Bayesian Ridge Regression and is similar to the classical Ridge
The parameters □□and□are estimated jointly during the fit of the model the regularization parameters □and□ being estimated by maximizing the log marginal likelihood The scikitlearn implementation is based on the algorithm described in Appendix A of Tipping 2001 where the update of the parameters □and□is done as suggested in MacKay 1992
The remaining hyperparameters are the parameters □1□2□1and□2of the gamma priors over □and□ These are usually chosen to be noninformative By default □1□2□1□2 10−6
Bayesian Ridge Regression is used for regression

```
 from sklearn import linearmodel
X  0 0 1 1 2 2 3 3
Y  0 1 2 3
reg  linearmodelBayesianRidge
regfitX Y
BayesianRidgealpha11e06 alpha21e06 computescoreFalse copyXTrue
fitinterceptTrue lambda11e06 lambda21e06 niter300
normalizeFalse tol0001 verboseFalse
```
After being fitted the model can then be used to predict new values
```
regpredict1 0
array050000013
```
The coefficients □of the model can be accessed
```
regcoef
array049999993 049999993
```
Due to the Bayesian framework the weights found are slightly different to the ones found by Ordinary Least Squares However Bayesian Ridge Regression is more robust to illposed problems

Examples

•Bayesian Ridge Regression

Automatic Relevance Determination ARD

ARDRegression is very similar to Bayesian Ridge Regression but can lead to sparser coefficients □12 ARDRegression poses a different prior over □ by dropping the assumption of the Gaussian being spherical Instead the distribution over □is assumed to be an axisparallel elliptical Gaussian distribution This means each coefficient □□is drawn from a Gaussian distribution centered on zero and with a precision □□ □□□ □□0 □−1 with diag □ □□1 □ □

In contrast to Bayesian Ridge Regression each coordinate of □□has its own standard deviation □□ The prior over all □□is chosen to be the same gamma distribution given by hyperparameters □1and□2

ARD is also known in the literature as Sparse Bayesian Learning andRelevance Vector Machine34

References
Logistic regression
Logistic regression despite its name is a linear model for classification rather than regression Logistic regression is also known in the literature as logit regression maximumentropy classification MaxEnt or the loglinear classifier In this model the probabilities describing the possible outcomes of a single trial are modeled using a logistic function Logistic regression is implemented in LogisticRegression This implementation can fit binary OnevsRest or multinomial logistic regression with optional ℓ1ℓ2or ElasticNet regularization
Note Regularization is applied by default which is common in machine learning but not in statistics Another advantage of regularization is that it improves numerical stability No regularization amounts to setting C to a very high value
As an optimization problem binary class ℓ2penalized logistic regression minimizes the following cost function
min
□□1
2□□□□□Σ
□1logexp−□□□□
□□□ 1
Similarly ℓ1regularized logistic regression solves the following optimization problem
min
□□‖□‖1□□Σ
□1logexp−□□□□
□□□ 1
ElasticNet regularization is a combination of ℓ1andℓ2 and minimizes the following cost function
min
□□1−□
2□□□□‖□‖1□□Σ
□1logexp−□□□□
□□□ 1

where controls the strength of ℓ1regularization vs ℓ2regularization it corresponds to the l1ratio parameter
Note that in this notation it’s assumed that the target takes values in the set −11at trial We can also see that
ElasticNet is equivalent to ℓ1when 1and equivalent to ℓ2when 0
The solvers implemented in the class LogisticRegression are “liblinear” “newtoncg” “lbfgs” “sag” and
“saga”
The solver “liblinear” uses a coordinate descent CD algorithm and relies on the excellent C LIBLINEAR library
which is shipped with scikitlearn However the CD algorithm implemented in liblinear cannot learn a true multi
nomial multiclass model instead the optimization problem is decomposed in a “onevsrest” fashion so separate
binary classifiers are trained for all classes This happens under the hood so LogisticRegression instances us
ing this solver behave as multiclass classifiers For ℓ1regularization sklearnsvml1minc allows to calculate
the lower bound for C in order to get a non “null” all feature weights to zero model
The “lbfgs” “sag” and “newtoncg” solvers only support ℓ2regularization or no regularization and are found to
converge faster for some highdimensional data Setting multiclass to “multinomial” with these solvers learns
a true multinomial logistic regression model5 which means that its probability estimates should be better calibrated
than the default “onevsrest” setting
The “sag” solver uses Stochastic Average Gradient descent6 It is faster than other solvers for large datasets when
both the number of samples and the number of features are large
The “saga” solver7is a variant of “sag” that also supports the nonsmooth penaltyl1 This is there
fore the solver of choice for sparse multinomial logistic regression It is also the only solver that supports
penaltyelasticnet
The “lbfgs” is an optimization algorithm that approximates the Broyden–Fletcher–Goldfarb–Shanno algorithm8
which belongs to quasiNewton methods The “lbfgs” solver is recommended for use for small datasets but for
larger datasets its performance suffers9
The following table summarizes the penalties supported by each solver
Solvers
Penalties ‘liblinear’ ‘lbfgs’ ‘newtoncg’ ‘sag’ ‘saga’
Multinomial L2 penalty no yes yes yes yes
OVR L2 penalty yes yes yes yes yes
Multinomial L1 penalty no no no no yes
OVR L1 penalty yes no no no yes
ElasticNet no no no no yes
No penalty ‘none’ no yes yes yes yes
Behaviors
Penalize the intercept bad yes no no no no
Faster for large datasets no no no yes yes
Robust to unscaled datasets yes yes yes no no
The “lbfgs” solver is used by default for its robustness For large datasets the “saga” solver is usually faster For large
dataset you may also consider using SGDClassifier with ‘log’ loss which might be even faster but requires more
tuning

Examples
•L1 Penalty and Sparsity in Logistic Regression
•Regularization path of L1 Logistic Regression
•Plot multinomial and OnevsRest Logistic Regression
•Multiclass sparse logisitic regression on newgroups20
•MNIST classfification using multinomial logistic L1
Differences from liblinear
There might be a difference in the scores obtained between LogisticRegression withsolverliblinear
orLinearSVC and the external liblinear library directly when fitinterceptFalse and the fit coef
or the data to be predicted are zeroes This is because for the samples with decisionfunction zero
LogisticRegression andLinearSVC predict the negative class while liblinear predicts the positive class
Note that a model with fitinterceptFalse and having many samples with decisionfunction zero
is likely to be a underfit bad model and you are advised to set fitinterceptTrue and increase the inter
ceptscaling
Note Feature selection with sparse logistic regression
A logistic regression with ℓ1penalty yields sparse models and can thus be used to perform feature selection as
detailed in L1based feature selection
LogisticRegressionCV implements Logistic Regression with builtin crossvalidation support to find the opti
malCandl1ratio parameters according to the scoring attribute The “newtoncg” “sag” “saga” and “lbfgs”
solvers are found to be faster for highdimensional dense data due to warmstarting see Glossary

Stochastic Gradient Descent SGD
Stochastic gradient descent is a simple yet very efficient approach to fit linear models It is particularly useful when the
number of samples and the number of features is very large The partialfit method allows onlineoutofcore
learning
The classes SGDClassifier andSGDRegressor provide functionality to fit linear models for classifica
tion and regression using different convex loss functions and different penalties Eg with losslog
SGDClassifier fits a logistic regression model while with losshinge it fits a linear support vector ma
chine SVM
References
•Stochastic Gradient Descent

Perceptron
ThePerceptron is another simple classification algorithm suitable for large scale learning By default
• It does not require a learning rate
• It is not regularized penalized
• It updates its model only on mistakes
The last characteristic implies that the Perceptron is slightly faster to train than SGD with the hinge loss and that the resulting models are sparser
Passive Aggressive Algorithms
The passiveaggressive algorithms are a family of algorithms for largescale learning They are similar to the Perceptron in that they do not require a learning rate However contrary to the Perceptron they include a regularization parameterC
For classification PassiveAggressiveClassifier can be used with losshinge PAI or losssquaredhinge PAII For regression PassiveAggressiveRegressor can be used with lossepsiloninsensitive PAI orlosssquaredepsiloninsensitive PAII

Robustness regression outliers and modeling errors
Robust regression aims to fit a regression model in the presence of corrupt data either outliers or error in the model
Different scenario and useful concepts
There are different things to keep in mind when dealing with data corrupted by outliers

•Outliers in X or in y
Outliers in the y direction Outliers in the X direction
•Fraction of outliers versus amplitude of error
The number of outlying points matters but also how much they are outliers
Small outliers Large outliers
An important notion of robust fitting is that of breakdown point the fraction of data that can be outlying for the fit to start missing the inlying data
Note that in general robust fitting in highdimensional setting large nfeatures is very hard The robust models here will probably not work in these settings
Tradeoffs which estimator
Scikitlearn provides 3 robust regression estimators RANSAC Theil Sen andHuberRegressor
•HuberRegressor should be faster than RANSAC andTheil Sen unless the number of samples are very large ie nsamples nfeatures This is because RANSAC andTheil Sen fit on smaller subsets of the data However both Theil Sen andRANSAC are unlikely to be as robust as HuberRegressor for the default parameters

•RANSAC is faster than Theil Sen and scales much better with the number of samples
•RANSAC will deal better with large outliers in the y direction most common situation
•Theil Sen will cope better with mediumsize outliers in the X direction but this property will disappear in highdimensional settings
When in doubt use RANSAC
RANSAC RANdom SAmple Consensus
RANSAC RANdom SAmple Consensus fits a model from random subsets of inliers from the complete data set
RANSAC is a nondeterministic algorithm producing only a reasonable result with a certain probability which is dependent on the number of iterations see maxtrials parameter It is typically used for linear and nonlinear regression problems and is especially popular in the field of photogrammetric computer vision
The algorithm splits the complete input sample data into a set of inliers which may be subject to noise and outliers which are eg caused by erroneous measurements or invalid hypotheses about the data The resulting model is then estimated only from the determined inliers
Details of the algorithm
Each iteration performs the following steps
1 Selectminsamples random samples from the original data and check whether the set of data is valid see isdatavalid
2 Fit a model to the random subset baseestimatorfit and check whether the estimated model is valid seeismodelvalid
3 Classify all data as inliers or outliers by calculating the residuals to the estimated model baseestimator predictX y all data samples with absolute residuals smaller than the residualthreshold are considered as inliers
4 Save fitted model as best model if number of inlier samples is maximal In case the current estimated model has the same number of inliers it is only considered as the best model if it has better score

These steps are performed either a maximum number of times maxtrials or until one of the special stop criteria are met see stopninliers andstopscore The final model is estimated using all inlier samples consensus set of the previously determined best model
Theisdatavalid andismodelvalid functions allow to identify and reject degenerate combinations of random subsamples If the estimated model is not needed for identifying degenerate cases isdatavalid should be used as it is called prior to fitting the model and thus leading to better computational performance
Examples

TheilSen estimator generalizedmedianbased estimator
TheTheilSenRegressor estimator uses a generalization of the median in multiple dimensions It is thus robust to multivariate outliers Note however that the robustness of the estimator decreases quickly with the dimensionality of the problem It loses its robustness properties and becomes no better than an ordinary least squares in high dimension
Examples
•TheilSen Regression
•Robust linear estimator fitting
References
• httpsenwikipediaorgwikiTheilE28093Senestimator
Theoretical considerations
TheilSenRegressor is comparable to the Ordinary Least Squares OLS in terms of asymptotic efficiency and as an unbiased estimator In contrast to OLS TheilSen is a nonparametric method which means it makes no assumption about the underlying distribution of the data Since TheilSen is a medianbased estimator it is more robust against corrupted data aka outliers In univariate setting TheilSen has a breakdown point of about 293 in case of a simple linear regression which means that it can tolerate arbitrary corrupted data of up to 293

The implementation of TheilSenRegressor in scikitlearn follows a generalization to a multivariate linear re
gression model10using the spatial median which is a generalization of the median to multiple dimensions11
In terms of time and space complexity TheilSen scales according to
samples
subsamples
which makes it infeasible to be applied exhaustively to problems with a large number of samples and features There
fore the magnitude of a subpopulation can be chosen to limit the time and space complexity by considering only a
random subset of all possible combinations
Examples
•TheilSen Regression
References
Huber Regression
TheHuberRegressor is different to Ridge because it applies a linear loss to samples that are classified as outliers
A sample is classified as an inlier if the absolute error of that sample is lesser than a certain threshold It differs from
TheilSenRegressor andRANSACRegressor because it does not ignore the effect of the outliers but gives a
lesser weight to them
The loss function that HuberRegressor minimizes is given by
min

where
□□□
□2 if□ □
2□□−□2otherwise
It is advised to set the parameter epsilon to 135 to achieve 95 statistical efficiency
Notes
TheHuberRegressor differs from using SGDRegressor with loss set to huber in the following ways
•HuberRegressor is scaling invariant Once epsilon is set scaling Xandydown or up by different values would produce the same robustness to outliers as before as compared to SGDRegressor whereepsilon has to be set again when Xandyare scaled
•HuberRegressor should be more efficient to use on data with small number of samples while SGDRegressor needs a number of passes on the training data to produce the same robustness
Examples
•HuberRegressor vs Ridge on dataset with strong outliers
References
• Peter J Huber Elvezio M Ronchetti Robust Statistics Concomitant scale estimates pg 172
Note that this estimator is different from the R implementation of Robust Regression httpwwwwatsuclaedustatr daerreghtm because the R implementation does a weighted least squares implementation with weights given to each sample on the basis of how much the residual is greater than a certain threshold
Polynomial regression extending linear models with basis functions
One common pattern within machine learning is to use linear models trained on nonlinear functions of the data This approach maintains the generally fast performance of linear methods while allowing them to fit a much wider range of data

For example a simple linear regression can be extended by constructing polynomial features from the coefficients
In the standard linear regression case you might have a model that looks like this for twodimensional data
□□ □ □0□1□1□2□2
If we want to fit a paraboloid to the data instead of a plane we can combine the features in secondorder polynomials
so that the model looks like this
□□ □ □0□1□1□2□2□3□1□2□4□2
1□5□2
2
The sometimes surprising observation is that this is still a linear model to see this imagine creating a new set of
features
□ □1 □2 □1□2 □2
1 □2
2
With this relabeling of the data our problem can be written
□□ □ □0□1□1□2□2□3□3□4□4□5□5
We see that the resulting polynomial regression is in the same class of linear models we considered above ie the
model is linear in □ and can be solved by the same techniques By considering linear fits within a higherdimensional
space built with these basis functions the model has the flexibility to fit a much broader range of data
Here is an example of applying this idea to onedimensional data using polynomial features of varying degrees
This figure is created using the PolynomialFeatures transformer which transforms an input data matrix into a
new data matrix of a given degree It can be used as follows
```
 from sklearnpreprocessing import PolynomialFeatures
 import numpy as np
X  nparange6reshape3 2
X
array0 1
2 3
4 5
poly  PolynomialFeaturesdegree2
polyfittransformX
array 1 0 1 0 0 1
 1 2 3 4 6 9
 1 4 5 16 20 25
```

The features of Xhave been transformed from □1 □2to1 □1 □2 □2
1 □1□2 □2
2 and can now be used within any
linear model
This sort of preprocessing can be streamlined with the Pipeline tools A single object representing a simple polynomial
regression can be created and used as follows
```
 from sklearnpreprocessing import PolynomialFeatures
 from sklearnlinearmodel import LinearRegression
 from sklearnpipeline import Pipeline
 import numpy as np
model  Pipelinepoly PolynomialFeaturesdegree3
 linear LinearRegressionfitintercept False
 fit to an order3 polynomial data
x  nparange5
y  3  2 x  x2  x3
model  modelfitx npnewaxis y
modelnamedstepslinearcoef
array 3 2 1 1
```
The linear model trained on polynomial features is able to exactly recover the input polynomial coefficients
In some cases it’s not necessary to include higher powers of any single feature but only the socalled interaction
features that multiply together at most □distinct features These can be gotten from PolynomialFeatures with
the settinginteractiononlyTrue
For example when dealing with boolean features □□
□□□for all □and is therefore useless but □□□□represents the
conjunction of two booleans This way we can solve the XOR problem with a linear classifier
```
 from sklearnlinearmodel import Perceptron
 from sklearnpreprocessing import PolynomialFeatures
 import numpy as np
X  nparray0 0 0 1 1 0 1 1
y  X 0  X 1
y
array0 1 1 0
X  PolynomialFeaturesinteractiononly TruefittransformXastypeint
X
array1 0 0 0
1 0 1 0
1 1 0 0
1 1 1 1
clf  Perceptronfitintercept False maxiter10 tol None
 shuffle FalsefitX y
```
And the classifier “predictions” are perfect
```
clfpredictX
array0 1 1 0
clfscoreX y
10
```
312 Linear and Quadratic Discriminant Analysis
Linear Discriminant Analysis discriminantanalysisLinearDiscriminantAnalysis and
Quadratic Discriminant Analysis discriminantanalysisQuadraticDiscriminantAnalysis
are two classic classifiers with as their names suggest a linear and a quadratic decision surface respectively

These classifiers are attractive because they have closedform solutions that can be easily computed are inherently multiclass have proven to work well in practice and have no hyperparameters to tune
The plot shows decision boundaries for Linear Discriminant Analysis and Quadratic Discriminant Analysis The bottom row demonstrates that Linear Discriminant Analysis can only learn linear boundaries while Quadratic Dis criminant Analysis can learn quadratic boundaries and is therefore more flexible
Examples
Linear and Quadratic Discriminant Analysis with covariance ellipsoid Comparison of LDA and QDA on synthetic data
Dimensionality reduction using Linear Discriminant Analysis
discriminantanalysisLinearDiscriminantAnalysis can be used to perform supervised dimen sionality reduction by projecting the input data to a linear subspace consisting of the directions which maximize the separation between classes in a precise sense discussed in the mathematics section below The dimension of the output is necessarily less than the number of classes so this is in general a rather strong dimensionality reduction and only makes sense in a multiclass setting

This is implemented in discriminantanalysisLinearDiscriminantAnalysistransform The
desired dimensionality can be set using the ncomponents constructor parameter This parameter has no influence

□□□
In the case of QDA there are no assumptions on the covariance matrices □□of the Gaussians leading to quadratic
decision surfaces See3for more details
Note Relation with Gaussian Naive Bayes
If in the QDA model one assumes that the covariance matrices are diagonal then the inputs are assumed to be con
ditionally independent in each class and the resulting classifier is equivalent to the Gaussian Naive Bayes classifier
naivebayesGaussianNB
3"The Elements of Statistical Learning" Hastie T Tibshirani R Friedman J Section 43 p106119 2008

Mathematical formulation of LDA dimensionality reduction
To understand the use of LDA in dimensionality reduction it is useful to start with a geometric reformulation of the LDA classification rule explained above We write for the total number of target classes Since in LDA we assume that all classes have the same estimated covariance we can rescale the data so that this covariance is the identity −12with
Then one can show that to classify a data point after scaling is equivalent to finding the estimated class mean which
is closest to the data point in the Euclidean distance But this can be done just as well after projecting on the −1 affine subspace generated by all the for all classes This shows that implicit in the LDA classifier there is a
dimensionality reduction by linear projection onto a −1dimensional space
We can reduce the dimension even more to a chosen by projecting onto the linear subspace which max
imizes the variance of the after projection in effect we are doing a form of PCA for the transformed class
means This corresponds to the ncomponents parameter used in the discriminantanalysis
LinearDiscriminantAnalysistransform method See3for more details
Shrinkage
Shrinkage is a tool to improve estimation of covariance matrices in situations where the number of training sam
ples is small compared to the number of features In this scenario the empirical sample covariance is a poor es
timator Shrinkage LDA can be used by setting the shrinkage parameter of the discriminantanalysis
LinearDiscriminantAnalysis class to ‘auto’ This automatically determines the optimal shrinkage parameter
in an analytic way following the lemma introduced by Ledoit and Wolf4 Note that currently shrinkage only works
when setting the solver parameter to ‘lsqr’ or ‘eigen’
Theshrinkage parameter can also be manually set between 0 and 1 In particular a value of 0 corresponds to
no shrinkage which means the empirical covariance matrix will be used and a value of 1 corresponds to complete
shrinkage which means that the diagonal matrix of variances will be used as an estimate for the covariance matrix
Setting this parameter to a value between these two extrema will estimate a shrunk version of the covariance matrix
4Ledoit O Wolf M Honey I Shrunk the Sample Covariance Matrix The Journal of Portfolio Management 304 110119 2004

Estimation algorithms
The default solver is ‘svd’ It can perform both classification and transform and it does not rely on the calculation of the covariance matrix This can be an advantage in situations where the number of features is large However the ‘svd’ solver cannot be used with shrinkage
The ‘lsqr’ solver is an efficient algorithm that only works for classification It supports shrinkage
The ‘eigen’ solver is based on the optimization of the between class scatter to within class scatter ratio It can be used for both classification and transform and it supports shrinkage However the ‘eigen’ solver needs to compute the covariance matrix so it might not be suitable for situations with a high number of features
Examples
Normal and Shrinkage Linear Discriminant Analysis for classification Comparison of LDA classifiers with and without shrinkage

313 Kernel ridge regression
Kernel ridge regression KRR M2012 combines Ridge Regression linear least squares with l2norm regularization with the kernel trick It thus learns a linear function in the space induced by the respective kernel and the data For nonlinear kernels this corresponds to a nonlinear function in the original space
The form of the model learned by KernelRidge is identical to support vector regression SVR However different loss functions are used KRR uses squared error loss while support vector regression uses □insensitive loss both combined with l2 regularization In contrast to SVR fittingKernelRidge can be done in closedform and is typically faster for mediumsized datasets On the other hand the learned model is nonsparse and thus slower than SVR which learns a sparse model for □ 0 at predictiontime
The following figure compares KernelRidge andSVR on an artificial dataset which consists of a sinusoidal target function and strong noise added to every fifth datapoint The learned model of KernelRidge andSVR is plotted where both complexityregularization and bandwidth of the RBF kernel have been optimized using gridsearch The learned functions are very similar however fitting KernelRidge is approx seven times faster than fitting SVR both with gridsearch However prediction of 100000 target values is more than three times faster with SVR since it has learned a sparse model using only approx 13 of the 100 training datapoints as support vectors
The next figure compares the time for fitting and prediction of KernelRidge andSVR for different sizes of the training set Fitting KernelRidge is faster than SVR for mediumsized training sets less than 1000 samples however for larger training sets SVR scales better With regard to prediction time SVR is faster than KernelRidge for all sizes of the training set because of the learned sparse solution Note that the degree of sparsity and thus the prediction time depends on the parameters □and□of theSVR□ 0would correspond to a dense model

314 Support Vector Machines
Support vector machines SVMs are a set of supervised learning methods used for classification regression and outliers detection

scikitlearn user guide Release 0213
31 Supervised learning 225

The advantages of support vector machines are
• Effective in high dimensional spaces
• Still effective in cases where number of dimensions is greater than the number of samples
• Uses a subset of training points in the decision function called support vectors so it is also memory efficient
• Versatile different Kernel functions can be specified for the decision function Common kernels are provided
but it is also possible to specify custom kernels
The disadvantages of support vector machines include
• If the number of features is much greater than the number of samples avoid overfitting in choosing Kernel
functions and regularization term is crucial
• SVMs do not directly provide probability estimates these are calculated using an expensive fivefold cross
validation see Scores and probabilities below
The support vector machines in scikitlearn support both dense numpyndarray and convertible to that by numpy
asarray and sparse any scipysparse sample vectors as input However to use an SVM to make predictions
for sparse data it must have been fit on such data For optimal performance use Cordered numpyndarray dense
orscipysparsecsrmatrix sparse with dtypefloat64
Classification
SVCNuSVC andLinearSVC are classes capable of performing multiclass classification on a dataset

SVC andNuSVC are similar methods but accept slightly different sets of parameters and have different mathematical formulations see section Mathematical formulation On the other hand LinearSVC is another implementation of Support Vector Classification for the case of a linear kernel Note that LinearSVC does not accept keyword kernel as this is assumed to be linear It also lacks some of the members of SVC andNuSVC likesupport
As other classifiers SVCNuSVC andLinearSVC take as input two arrays an array X of size nsamples nfeatures holding the training samples and an array y of class labels strings or integers size nsamples
```
 from sklearn import svm
X  0 0 1 1
y  0 1
clf  svmSVCgammascale
clffitX y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
```
After being fitted the model can then be used to predict new values
```
clfpredict2 2

SeeMathematical formulation for a complete description of the decision function
Note that the LinearSVC also implements an alternative multiclass strategy the socalled multiclass SVM formu
lated by Crammer and Singer by using the option multiclasscrammersinger This method is consis
tent which is not true for onevsrest classification In practice onevsrest classification is usually preferred since
the results are mostly similar but the runtime is significantly less
For “onevsrest” LinearSVC the attributes coef andintercept have the shape nclass
nfeatures andnclass respectively Each row of the coefficients corresponds to one of the nclass
many “onevsrest” classifiers and similar for the intercepts in the order of the “one” class
In the case of “onevsone” SVC the layout of the attributes is a little more involved In the case of having
a linear kernel the attributes coef andintercept have the shape nclass nclass 1
2 nfeatures andnclass nclass 1 2 respectively This is similar to the layout for
LinearSVC described above with each row now corresponding to a binary classifier The order for classes 0 to n is
“0 vs 1” “0 vs 2” “0 vs n” “1 vs 2” “1 vs 3” “1 vs n” “n1 vs n”
The shape of dualcoef isnclass1 nSV with a somewhat hard to grasp layout The columns corre
spond to the support vectors involved in any of the nclass nclass 1 2 “onevsone” classifiers
Each of the support vectors is used in nclass 1 classifiers The nclass 1 entries in each row correspond
to the dual coefficients for these classifiers
This might be made more clear by an example
Consider a three class problem with class 0 having three support vectors □0
0 □1

Scores and probabilities
Thedecisionfunction method ofSVC andNuSVC gives perclass scores for each sample or a single score per sample in the binary case When the constructor option probability is set toTrue class membership probability estimates from the methods predictproba andpredictlogproba are enabled In the binary case the probabilities are calibrated using Platt scaling logistic regression on the SVM's scores fit by an additional crossvalidation on the training data In the multiclass case this is extended as per Wu et al 2004
Needless to say the crossvalidation involved in Platt scaling is an expensive operation for large datasets In addition the probability estimates may be inconsistent with the scores in the sense that the "argmax" of the scores may not be the argmax of the probabilities Eg in binary classification a sample may be labeled by predict as belonging to a class that has probability ½ according to predictproba Platt's method is also known to have theoret ical issues If confidence scores are required but these do not have to be probabilities then it is advisable to set probabilityFalse and usedecisionfunction instead ofpredictproba

Unbalanced problems
In problems where it is desired to give more importance to certain classes or certain individual samples keywords classweight andsampleweight can be used
SVC but notNuSVC implement a keyword classweight in thefit method It's a dictionary of the form classlabel value where value is a floating point number 0 that sets the parameter Cof class classlabel toCvalue

SVCNuSVC SVRNuSVR andOneClassSVM implement also weights for individual samples in method fit through keyword sampleweight Similar to classweight these set the parameter Cfor the ith example to Csampleweighti

Examples

•Plot different SVM classifiers in the iris dataset
•SVM Maximum margin separating hyperplane
•SVM Separating hyperplane for unbalanced classes
•SVMAnova SVM with univariate feature selection
•Nonlinear SVM
•SVM Weighted samples

Regression

The method of Support Vector Classification can be extended to solve regression problems This method is called Support Vector Regression

The model produced by support vector classification as described above depends only on a subset of the training data because the cost function for building the model does not care about training points that lie beyond the margin Analogously the model produced by Support Vector Regression depends only on a subset of the training data because the cost function for building the model ignores any training data close to the model prediction

There are three different implementations of Support Vector Regression SVRNuSVR andLinearSVR LinearSVR provides a faster implementation than SVR but only considers linear kernels while NuSVR implements a slightly different formulation than SVR andLinearSVR See Implementation details for further details

As with classification classes the fit method will take as argument vectors X y only that in this case y is expected to have floating point values instead of integer values

Examples
•Support Vector Regression SVR using linear and nonlinear kernels
Density estimation novelty detection
The classOneClassSVM implements a OneClass SVM which is used in outlier detection
SeeNovelty and Outlier Detection for the description and usage of OneClassSVM
Complexity
Support Vector Machines are powerful tools but their compute and storage requirements increase rapidly with the number of training vectors The core of an SVM is a quadratic programming problem QP separating support vectors from the rest of the training data The QP solver used by this libsvmbased implementation scales between □□□□□□□□□□×□2
□□□□□□□ and□□□□□□□□□□×□3
□□□□□□□ depending on how efficiently the libsvm cache is used in
practice dataset dependent If the data is very sparse □□□□□□□□□ should be replaced by the average number of non zero features in a sample vector
Also note that for the linear case the algorithm used in LinearSVC by the liblinear implementation is much more efficient than its libsvmbased SVC counterpart and can scale almost linearly to millions of samples andor features
Tips on Practical Use
•Avoiding data copy ForSVCSVRNuSVC andNuSVR if the data passed to certain methods is not Cordered contiguous and double precision it will be copied before calling the underlying C implementation You can check whether a given numpy array is Ccontiguous by inspecting its flags attribute
ForLinearSVC andLogisticRegression any input passed as a numpy array will be copied and con verted to the liblinear internal sparse data representation double precision floats and int32 indices of nonzero components If you want to fit a largescale linear classifier without copying a dense numpy Ccontiguous double precision array as input we suggest to use the SGDClassifier class instead The objective function can be configured to be almost the same as the LinearSVC model
•Kernel cache size ForSVCSVRNuSVC andNuSVR the size of the kernel cache has a strong impact on run times for larger problems If you have enough RAM available it is recommended to set cachesize to a higher value than the default of 200MB such as 500MB or 1000MB
•Setting C Cis1by default and it’s a reasonable default choice If you have a lot of noisy observations you should decrease it It corresponds to regularize more the estimation
LinearSVC andLinearSVR are less sensitive to Cwhen it becomes large and prediction results stop im proving after a certain threshold Meanwhile larger Cvalues will take more time to train sometimes up to 10 times longer as shown by Fan et al 2008

• Support Vector Machine algorithms are not scale invariant so it is highly recommended to scale your data
For example scale each attribute on the input vector X to 01 or 11 or standardize it to have mean 0
and variance 1 Note that the same scaling must be applied to the test vector to obtain meaningful results See
section Preprocessing data for more details on scaling and normalization
• Parameter nuinNuSVC OneClassSVM NuSVR approximates the fraction of training errors and support vec
tors
• InSVC if data for classification are unbalanced eg many positive and few negative set
classweightbalanced andor try different penalty parameters C
•Randomness of the underlying implementations The underlying implementations of SVC andNuSVC use
a random number generator only to shuffle the data for probability estimation when probability is set to
True This randomness can be controlled with the randomstate parameter If probability is set
toFalse these estimators are not random and randomstate has no effect on the results The underlying
OneClassSVM implementation is similar to the ones of SVC andNuSVC As no probability estimation is
provided for OneClassSVM it is not random
The underlying LinearSVC implementation uses a random number generator to select features when fitting the
model with a dual coordinate descent ie when dual is set toTrue It is thus not uncommon to have slightly
different results for the same input data If that happens try with a smaller tol parameter This randomness
can also be controlled with the randomstate parameter When dual is set toFalse the underlying
implementation of LinearSVC is not random and randomstate has no effect on the results
• Using L1 penalization as provided by LinearSVClossl2 penaltyl1 dualFalse
yields a sparse solution ie only a subset of feature weights is different from zero and contribute to the de
cision function Increasing Cyields a more complex model more feature are selected The Cvalue that yields
a “null” model all weights equal to zero can be calculated using l1minc

Custom Kernels
You can define your own kernels by either giving the kernel as a python function or by precomputing the Gram matrix
Classifiers with custom kernels behave the same way as any other classifiers except that
• Fieldsupportvectors is now empty only indices of support vectors are stored in support
• A reference and not a copy of the first argument in the fit method is stored for future reference If that
array changes between the use of fit andpredict you will have unexpected results
Using Python functions as kernels
You can also use your own defined kernels by passing a function to the keyword kernel in the constructor
Your kernel must take as arguments two matrices of shape nsamples1 nfeatures nsamples2
nfeatures and return a kernel matrix of shape nsamples1 nsamples2
The following code defines a linear kernel and creates a classifier instance that will use that kernel
```
 import numpy as np
 from sklearn import svm
 def mykernelX Y
 return npdotX YT

clf  svmSVCkernelmykernel
```
Examples
•SVM with custom kernel
Using the Gram matrix
Setkernelprecomputed and pass the Gram matrix instead of X in the fit method At the moment the kernel
values between alltraining vectors and the test vectors must be provided
```
 import numpy as np
 from sklearn import svm
X  nparray0 0 1 1
y  0 1
clf  svmSVCkernelprecomputed
 linear kernel computation
gram  npdotX XT
clffitgram y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammaautodeprecated
kernelprecomputed maxiter1 probabilityFalse
randomstateNone shrinkingTrue tol0001 verboseFalse
 predict on training examples
clfpredictgram
array0 1
```

Parameters of the RBF Kernel
When training an SVM with the Radial Basis Function RBF kernel two parameters must be considered Cand gamma The parameter C common to all SVM kernels trades off misclassification of training examples against simplicity of the decision surface A low Cmakes the decision surface smooth while a high Caims at classifying all training examples correctly gamma defines how much influence a single training example has The larger gamma is the closer other examples must be to be affected
Proper choice of Candgamma is critical to the SVM’s performance One is advised to use sklearn modelselectionGridSearchCV withCandgamma spaced exponentially far apart to choose good values
Examples
•RBF SVM parameters
Mathematical formulation
A support vector machine constructs a hyperplane or set of hyperplanes in a high or infinite dimensional space which can be used for classification regression or other tasks Intuitively a good separation is achieved by the hyperplane that has the largest distance to the nearest training data points of any class socalled functional margin since in general the larger the margin the lower the generalization error of the classifier

SVC
Given training vectors □□∈R□ i1 n in two classes and a vector □∈1−1□ SVC solves the following primal problem
min
□□□1

315 Stochastic Gradient Descent
Stochastic Gradient Descent SGD is a simple yet very efficient approach to discriminative learning of linear clas
sifiers under convex loss functions such as linear Support Vector Machines and Logistic Regression Even though

SGD has been around in the machine learning community for a long time it has received a considerable amount of attention just recently in the context of largescale learning
SGD has been successfully applied to largescale and sparse machine learning problems often encountered in text classification and natural language processing Given that the data is sparse the classifiers in this module easily scale to problems with more than 105 training examples and more than 105 features
The advantages of Stochastic Gradient Descent are
• Efficiency
• Ease of implementation lots of opportunities for code tuning
The disadvantages of Stochastic Gradient Descent include
• SGD requires a number of hyperparameters such as the regularization parameter and the number of iterations
• SGD is sensitive to feature scaling
Classification
Warning Make sure you permute shuffle your training data before fitting the model or use shuffleTrue to shuffle after each iteration
The classSGDClassifier implements a plain stochastic gradient descent learning routine which supports different loss functions and penalties for classification
As other classifiers SGD has to be fitted with two arrays an array X of size nsamples nfeatures holding the training samples and an array Y of size nsamples holding the target values class labels for the training samples
```
 from sklearnlinearmodel import SGDClassifier
X  0 0 1 1
```

y 0 1
clf SGDClassifierlosshinge penaltyl2 maxiter5
clffitX y

The concrete loss function can be set via the loss parameter SGDClassifier supports the following loss func
tions
•losshinge softmargin linear Support Vector Machine
•lossmodifiedhuber smoothed hinge loss
•losslog logistic regression
• and all regression losses below
The first two loss functions are lazy they only update the model parameters if an example violates the margin con
straint which makes training very efficient and may result in sparser models even when L2 penalty is used
Usinglosslog orlossmodifiedhuber enables the predictproba method which gives a vector
of probability estimates □□□per sample □
clf SGDClassifierlosslog maxiter5fitX y
clfpredictproba1 1
array000 099
The concrete penalty can be set via the penalty parameter SGD supports the following penalties
•penaltyl2 L2 norm penalty on coef
•penaltyl1 L1 norm penalty on coef

•penaltyelasticnet Convex combination of L2 and L1 1 l1ratio L2
l1ratio L1
The default setting is penaltyl2 The L1 penalty leads to sparse solutions driving most coefficients to zero
The Elastic Net solves some deficiencies of the L1 penalty in the presence of highly correlated attributes The param
eterl1ratio controls the convex combination of L1 and L2 penalty
SGDClassifier supports multiclass classification by combining multiple binary classifiers in a “one versus all”
OV A scheme For each of the □classes a binary classifier is learned that discriminates between that and all other
□−1classes At testing time we compute the confidence score ie the signed distances to the hyperplane for each
classifier and choose the class with the highest confidence The Figure below illustrates the OV A approach on the iris
dataset The dashed lines represent the three OV A classifiers the background colors show the decision surface induced
by the three classifiers
In the case of multiclass classification coef is a twodimensional array of shapenclasses
nfeatures andintercept is a onedimensional array of shapenclasses The ith row of coef
holds the weight vector of the OV A classifier for the ith class classes are indexed in ascending order see at
tributeclasses Note that in principle since they allow to create a probability model losslog and
lossmodifiedhuber are more suitable for onevsall classification
SGDClassifier supports both weighted classes and weighted instances via the fit parameters classweight
andsampleweight See the examples below and the docstring of SGDClassifierfit for further informa
tion
Examples
•SGD Maximum margin separating hyperplane
•Plot multiclass SGD on the iris dataset
•SGD Weighted samples
•Comparing various online solvers

•SVM Separating hyperplane for unbalanced classes See theNote
SGDClassifier supports averaged SGD ASGD Averaging can be enabled by setting averageTrue
ASGD works by averaging the coefficients of the plain SGD over each iteration over a sample When using ASGD the learning rate can be larger and even constant leading on some datasets to a speed up in training time
For classification with a logistic loss another variant of SGD with an averaging strategy is available with Stochastic Average Gradient SAG algorithm available as a solver in LogisticRegression
Regression
The classSGDRegressor implements a plain stochastic gradient descent learning routine which supports different loss functions and penalties to fit linear regression models SGDRegressor is well suited for regression problems with a large number of training samples 10000 for other problems we recommend Ridge Lasso or ElasticNet
The concrete loss function can be set via the loss parameterSGDRegressor supports the following loss functions
•losssquaredloss Ordinary least squares
•losshuber Huber loss for robust regression
•lossepsiloninsensitive linear Support Vector Regression
The Huber and epsiloninsensitive loss functions can be used for robust regression The width of the insensitive region has to be specified via the parameter epsilon This parameter depends on the scale of the target variables
SGDRegressor supports averaged SGD as SGDClassifier Averaging can be enabled by setting averageTrue
For regression with a squared loss and a l2 penalty another variant of SGD with an averaging strategy is available with Stochastic Average Gradient SAG algorithm available as a solver in Ridge
Stochastic Gradient Descent for sparse data
Note The sparse implementation produces slightly different results than the dense implementation due to a shrunk learning rate for the intercept
There is builtin support for sparse data given in any matrix in a format supported by scipysparse For maximum efficiency however use the CSR matrix format as defined in scipysparsecsrmatrix
Examples
•Classification of text documents using sparse features
Complexity
The major advantage of SGD is its efficiency which is basically linear in the number of training examples If X is a matrix of size n p training has a cost of □□□□□ where k is the number of iterations epochs and □□is the average number of nonzero attributes per sample
Recent theoretical results however show that the runtime to get some desired optimization accuracy does not increase as the training set size increases

Stopping criterion
The classes SGDClassifier andSGDRegressor provide two criteria to stop the algorithm when a given level of convergence is reached
• WithearlystoppingTrue the input data is split into a training set and a validation set The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set The size of the validation set can be changed with the parameter validationfraction
• WithearlystoppingFalse the model is fitted on the entire input data and the stopping criterion is based on the objective function computed on the input data
In both cases the criterion is evaluated once by epoch and the algorithm stops when the criterion does not improve niternochange times in a row The improvement is evaluated with a tolerance tol and the algorithm stops in any case after a maximum number of iteration maxiter
Tips on Practical Use
• Stochastic Gradient Descent is sensitive to feature scaling so it is highly recommended to scale your data For example scale each attribute on the input vector X to 01 or 11 or standardize it to have mean 0 and variance 1 Note that the same scaling must be applied to the test vector to obtain meaningful results This can be easily done using StandardScaler
from sklearnpreprocessing import StandardScaler
scaler StandardScaler
scalerfitXtrain Dont cheat fit only on training data
Xtrain scalertransformXtrain
Xtest scalertransformXtest apply same transformation to test data
If your attributes have an intrinsic scale eg word frequencies or indicator features scaling is not needed
• Finding a reasonable regularization term □is best done using GridSearchCV usually in the range 10 0npарange17
• Empirically we found that SGD converges after observing approx 106 training samples Thus a reasonable first guess for the number of iterations is maxiter npceil10 6 n wherenis the size of the training set
• If you apply SGD to features extracted using PCA we found that it is often wise to scale the feature values by some constant csuch that the average L2 norm of the training data equals one
• We found that Averaged SGD works best with a larger number of features and a higher eta0

Implementation details
The implementation of SGD is influenced by the Stochastic Gradient SVM of Léon Bottou Similar to SvmSGD the weight vector is represented as the product of a scalar and a vector which allows an efficient weight update in the case of L2 regularization In the case of sparse feature vectors the intercept is updated with a smaller learning rate multiplied by 001 to account for the fact that it is updated more frequently Training examples are picked up sequentially and the learning rate is lowered after each observed example We adopted the learning rate schedule from ShalevShwartz et al 2007 For multiclass classification a “one versus all” approach is used We use the truncated gradient algorithm proposed by Tsuruoka et al 2009 for L1 regularization and the Elastic Net The code is written in Cython

316 Nearest Neighbors
sklearnneighbors provides functionality for unsupervised and supervised neighborsbased learning methods
Unsupervised nearest neighbors is the foundation of many other learning methods notably manifold learning and
spectral clustering Supervised neighborsbased learning comes in two flavors classification for data with discrete
labels and regression for data with continuous labels
The principle behind nearest neighbor methods is to find a predefined number of training samples closest in distance
to the new point and predict the label from these The number of samples can be a userdefined constant knearest
neighbor learning or vary based on the local density of points radiusbased neighbor learning The distance can
in general be any metric measure standard Euclidean distance is the most common choice Neighborsbased meth
ods are known as nongeneralizing machine learning methods since they simply “remember” all of its training data
possibly transformed into a fast indexing structure such as a Ball Tree orKD Tree
Despite its simplicity nearest neighbors has been successful in a large number of classification and regression prob
lems including handwritten digits and satellite image scenes Being a nonparametric method it is often successful in
classification situations where the decision boundary is very irregular
The classes in sklearnneighbors can handle either NumPy arrays or scipysparse matrices as input For
dense matrices a large number of possible distance metrics are supported For sparse matrices arbitrary Minkowski
metrics are supported for searches
There are many learning routines which rely on nearest neighbors at their core One example is kernel density estima
tion discussed in the density estimation section
Unsupervised Nearest Neighbors
NearestNeighbors implements unsupervised nearest neighbors learning It acts as a uniform interface to three
different nearest neighbors algorithms BallTree KDTree and a bruteforce algorithm based on routines in
sklearnmetricspairwise The choice of neighbors search algorithm is controlled through the keyword
algorithm which must be one of auto balltree kdtree brute When the de
fault value auto is passed the algorithm attempts to determine the best approach from the training data For a
discussion of the strengths and weaknesses of each option see Nearest Neighbor Algorithms
Warning Regarding the Nearest Neighbors algorithms if two neighbors 1and have identical
distances but different labels the result will depend on the ordering of the training data

Finding the Nearest Neighbors
For the simple task of finding the nearest neighbors between two sets of data the unsupervised algorithms within sklearnneighbors can be used
```
 from sklearnneighbors import NearestNeighbors
 import numpy as np
X  nparray1 1 2 1 3 2 1 1 2 1 3 2
nbrs  NearestNeighborsnneighbors2 algorithmballtreefitX
distances indices  nbrskneighborsX
indices
array0 1
1 0
2 1
3 4
4 3
5 4
distances
array0  1
0  1
0  141421356
0  1
0  1
0  141421356
```
Because the query set matches the training set the nearest neighbor of each point is the point itself at a distance of zero
It is also possible to efficiently produce a sparse graph showing the connections between neighboring points
```
nbrskneighborsgraphXtoarray
array1 1 0 0 0 0
1 1 0 0 0 0
0 1 1 0 0 0
0 0 0 1 1 0
0 0 0 1 1 0
0 0 0 0 1 1
```
The dataset is structured such that points nearby in index order are nearby in parameter space leading to an ap proximately blockdiagonal matrix of Knearest neighbors Such a sparse graph is useful in a variety of cir cumstances which make use of spatial relationships between points for unsupervised learning in particular seesklearnmanifoldIsomap sklearnmanifoldLocallyLinearEmbedding andsklearn clusterSpectralClustering
KDTree and BallTree Classes
Alternatively one can use the KDTree orBallTree classes directly to find nearest neighbors This is the function ality wrapped by the NearestNeighbors class used above The Ball Tree and KD Tree have the same interface we'll show an example of using the KD Tree here
```
 from sklearnneighbors import KDTree
 import numpy as np
X  nparray1 1 2 1 3 2 1 1 2 1 3 2
kdt  KDTreeX leafsize30 metriceuclidean
kdtqueryX k2 returndistance False
array0 1
```

Refer to the KDTree andBallTree class documentation for more information on the options available for nearest neighbors searches including specification of query strategies distance metrics etc For a list of available metrics see the documentation of the DistanceMetric class

Nearest Neighbors Classification

Neighborsbased classification is a type of instancebased learning ornongeneralizing learning it does not attempt to construct a general internal model but simply stores instances of the training data Classification is computed from a simple majority vote of the nearest neighbors of each point a query point is assigned the data class which has the most representatives within the nearest neighbors of the point

scikitlearn implements two different nearest neighbors classifiers KNeighborsClassifier implements learning based on the □nearest neighbors of each query point where □is an integer value specified by the user RadiusNeighborsClassifier implements learning based on the number of neighbors within a fixed radius □of each training point where □is a floatingpoint value specified by the user

The□neighbors classification in KNeighborsClassifier is the most commonly used technique The optimal choice of the value □is highly datadependent in general a larger □suppresses the effects of noise but makes the classification boundaries less distinct

In cases where the data is not uniformly sampled radiusbased neighbors classification in RadiusNeighborsClassifier can be a better choice The user specifies a fixed radius □ such that points in sparser neighborhoods use fewer nearest neighbors for the classification For highdimensional parameter spaces this method becomes less effective due to the socalled “curse of dimensionality”

The basic nearest neighbors classification uses uniform weights that is the value assigned to a query point is computed from a simple majority vote of the nearest neighbors Under some circumstances it is better to weight the neighbors such that nearer neighbors contribute more to the fit This can be accomplished through the weights keyword The default value weights uniform assigns uniform weights to each neighbor weights distance assigns weights proportional to the inverse of the distance from the query point Alternatively a userdefined function of the distance can be supplied to compute the weights

Examples
•Nearest Neighbors Classification an example of classification using nearest neighbors
Nearest Neighbors Regression
Neighborsbased regression can be used in cases where the data labels are continuous rather than discrete variables
The label assigned to a query point is computed based on the mean of the labels of its nearest neighbors
scikitlearn implements two different neighbors regressors KNeighborsRegressor implements learning
based on the nearest neighbors of each query point where is an integer value specified by the user
RadiusNeighborsRegressor implements learning based on the neighbors within a fixed radius of the query
point where is a floatingpoint value specified by the user
The basic nearest neighbors regression uses uniform weights that is each point in the local neighborhood contributes
uniformly to the classification of a query point Under some circumstances it can be advantageous to weight points
such that nearby points contribute more to the regression than faraway points This can be accomplished through the
weights keyword The default value weights uniform assigns equal weights to all points weights
 distance assigns weights proportional to the inverse of the distance from the query point Alternatively a
userdefined function of the distance can be supplied which will be used to compute the weights
The use of multioutput nearest neighbors for regression is demonstrated in Face completion with a multioutput
estimators In this example the inputs X are the pixels of the upper half of faces and the outputs Y are the pixels of
the lower half of those faces
Examples
•Nearest Neighbors regression an example of regression using nearest neighbors

bors
Nearest Neighbor Algorithms
Brute Force
Fast computation of nearest neighbors is an active area of research in machine learning The most naive neighbor search implementation involves the bruteforce computation of distances between all pairs of points in the dataset for □samples in □dimensions this approach scales as □□□2 Efficient bruteforce neighbors searches can be very competitive for small data samples However as the number of samples □grows the bruteforce approach quickly becomes infeasible In the classes within sklearnneighbors bruteforce neighbors searches are specified using the keyword algorithm brute and are computed using the routines available in sklearnmetrics pairwise
KD Tree
To address the computational inefficiencies of the bruteforce approach a variety of treebased data structures have been invented In general these structures attempt to reduce the required number of distance calculations by efficiently encoding aggregate distance information for the sample The basic idea is that if point □is very distant from point □ and point □is very close to point □ then we know that points □and□are very distant without having to explicitly calculate their distance In this way the computational cost of a nearest neighbors search can be reduced to □□□log□or better This is a significant improvement over bruteforce for large □
An early approach to taking advantage of this aggregate information was the KD tree data structure short for K dimensional tree which generalizes twodimensional Quadtrees and 3dimensional Octtrees to an arbitrary number of dimensions The KD tree is a binary tree structure which recursively partitions the parameter space along the data axes dividing it into nested orthotropic regions into which data points are filed The construction of a KD tree is very fast because partitioning is performed only along the data axes no □dimensional distances need to be computed Once constructed the nearest neighbor of a query point can be determined with only □log□distance computations Though the KD tree approach is very fast for lowdimensional □ 20 neighbors searches it becomes inefficient as□grows very large this is one manifestation of the socalled “curse of dimensionality” In scikitlearn KD tree neighbors searches are specified using the keyword algorithm kdtree and are computed using the class KDTree
References
• “Multidimensional binary search trees used for associative searching” Bentley JL Communications of the ACM 1975
Ball Tree
To address the inefficiencies of KD Trees in higher dimensions the ball tree data structure was developed Where KD trees partition data along Cartesian axes ball trees partition data in a series of nesting hyperspheres This makes tree construction more costly than that of the KD tree but results in a data structure which can be very efficient on highly structured data even in very high dimensions
A ball tree recursively divides the data into nodes defined by a centroid □and radius □ such that each point in the node lies within the hypersphere defined by □and□ The number of candidate points for a neighbor search is reduced

through use of the triangle inequality
□□≤□□
With this setup a single distance calculation between a test point and the centroid is sufficient to determine a lower and upper bound on the distance to all points within the node Because of the spherical geometry of the ball tree nodes it can outperform a KDtree in high dimensions though the actual performance is highly dependent on the structure of the training data In scikitlearn balltreebased neighbors searches are specified using the keyword algorithm balltree and are computed using the class sklearnneighborsBallTree Alternatively the user can work with the BallTree class directly

Choice of Nearest Neighbors Algorithm

The optimal algorithm for a given dataset is a complicated choice and depends on a number of factors

• number of samples □iensamples and dimensionality □ienfeatures
–Brute force query time grows as □□□
–Ball tree query time grows as approximately □□log□
–KD tree query time changes with □in a way that is difficult to precisely characterise For small □less than 20 or so the cost is approximately □□log□ and the KD tree query can be very efficient For larger □ the cost increases to nearly □□□ and the overhead due to the tree structure can lead to queries which are slower than brute force

For small data sets □less than 30 or so log□is comparable to □ and brute force algorithms can be more efficient than a treebased approach Both KDTree andBallTree address this through providing a leaf size parameter this controls the number of samples at which a query switches to bruteforce This allows both algorithms to approach the efficiency of a bruteforce computation for small □

• data structure intrinsic dimensionality of the data andor sparsity of the data Intrinsic dimensionality refers to the dimension □≤□of a manifold on which the data lies which can be linearly or nonlinearly embedded in the parameter space Sparsity refers to the degree to which the data fills the parameter space this is to be distinguished from the concept as used in “sparse” matrices The data matrix may have no zero entries but the structure can still be “sparse” in this sense
–Brute force query time is unchanged by data structure
–Ball tree andKD tree query times can be greatly influenced by data structure In general sparser data with a smaller intrinsic dimensionality leads to faster query times Because the KD tree internal representation is aligned with the parameter axes it will not generally show as much improvement as ball tree for arbitrarily structured data

Datasets used in machine learning tend to be very structured and are very wellsuited for treebased queries

• number of neighbors □requested for a query point
–Brute force query time is largely unaffected by the value of □
–Ball tree andKD tree query time will become slower as □increases This is due to two effects first a larger □leads to the necessity to search a larger portion of the parameter space Second using □ 1 requires internal queueing of results as the tree is traversed

As□becomes large compared to □ the ability to prune branches in a treebased query is reduced In this situation Brute force queries can be more efficient
• number of query points Both the ball tree and the KD Tree require a construction phase The cost of this construction becomes negligible when amortized over many queries If only a small number of queries will be performed however the construction can make up a significant fraction of the total cost If very few query points will be required brute force is better than a treebased method
Currently algorithm auto selectsbrute if□ □2 the input data is sparse or effectivemetric isn't in the VALIDMETRICS list for either kdtree orballtree Otherwise it selects the first out of kdtree andballtree that haseffectivemetric in itsVALIDMETRICS list This choice is based on the assumption that the number of query points is at least the same order as the number of training points and that leafsize is close to its default value of 30
Effect ofleafsize
As noted above for small sample sizes a brute force search can be more efficient than a treebased query This fact is accounted for in the ball tree and KD tree by internally switching to brute force searches within leaf nodes The level of this switch can be specified with the parameter leafsize This parameter choice has many effects
construction time A largerleafsize leads to a faster tree construction time because fewer nodes need to be created
query time Both a large or small leafsize can lead to suboptimal query cost For leafsize approaching 1 the overhead involved in traversing nodes can significantly slow query times For leafsize approach ing the size of the training set queries become essentially brute force A good compromise between these is leafsize 30 the default value of the parameter
memory Asleafsize increases the memory required to store a tree structure decreases This is especially important in the case of ball tree which stores a □dimensional centroid for each node The required storage space forBallTree is approximately 1 leafsize times the size of the training set
leafsize is not referenced for brute force queries
Nearest Centroid Classifier
TheNearestCentroid classifier is a simple algorithm that represents each class by the centroid of its members In effect this makes it similar to the label updating phase of the sklearnKMeans algorithm It also has no param eters to choose making it a good baseline classifier It does however suffer on nonconvex classes as well as when classes have drastically different variances as equal variance in all dimensions is assumed See Linear Discrim inant Analysis sklearndiscriminantanalysisLinearDiscriminantAnalysis and Quadratic Discriminant Analysis sklearndiscriminantanalysisQuadraticDiscriminantAnalysis for more complex methods that do not make this assumption Usage of the default NearestCentroid is simple

```
 from sklearnneighborsnearestcentroid import NearestCentroid
 import numpy as np
X  nparray1 1 2 1 3 2 1 1 2 1 3 2
y  nparray1 1 1 2 2 2
clf  NearestCentroid
clffitX y
NearestCentroidmetriceuclidean shrinkthresholdNone
printclfpredict08 1
1
```

Nearest Shrunken Centroid
TheNearestCentroid classifier has a shrinkthreshold parameter which implements the nearest shrunken centroid classifier In effect the value of each feature for each centroid is divided by the withinclass variance of that feature The feature values are then reduced by shrinkthreshold Most notably if a particular feature value crosses zero it is set to zero In effect this removes the feature from affecting the classification This is useful for example for removing noisy features
In the example below using a small shrink threshold increases the accuracy of the model from 081 to 082
Examples
•Nearest Centroid Classification an example of classification using nearest centroid with different shrink thresholds
Neighborhood Components Analysis
Neighborhood Components Analysis NCA NeighborhoodComponentsAnalysis is a distance metric learning algorithm which aims to improve the accuracy of nearest neighbors classification compared to the standard Euclidean distance The algorithm directly maximizes a stochastic variant of the leaveoneout knearest neighbors KNN score on the training set It can also learn a lowdimensional linear projection of data that can be used for data visualization and fast classification

In the above illustrating figure we consider some points from a randomly generated dataset We focus on the stochastic KNN classification of point no 3 The thickness of a link between sample 3 and another point is proportional to their distance and can be seen as the relative weight or probability that a stochastic nearest neighbor prediction rule would assign to this point In the original space sample 3 has many stochastic neighbors from various classes so the right class is not very likely However in the projected space learned by NCA the only stochastic neighbors with non negligible weight are from the same class as sample 3 guaranteeing that the latter will be well classified See the mathematical formulation for more details

Classification

Combined with a nearest neighbors classifier KNeighborsClassifier NCA is attractive for classification be cause it can naturally handle multiclass problems without any increase in the model size and does not introduce additional parameters that require finetuning by the user

NCA classification has been shown to work well in practice for data sets of varying size and difficulty In contrast to related methods such as Linear Discriminant Analysis NCA does not make any assumptions about the class distribu tions The nearest neighbor classification can naturally produce highly irregular decision boundaries

To use this model for classification one needs to combine a NeighborhoodComponentsAnalysis instance that learns the optimal transformation with a KNeighborsClassifier instance that performs the classification in the projected space Here is an example using the two classes

```
 from sklearnneighbors import NeighborhoodComponentsAnalysis
KNeighborsClassifier
 from sklearndatasets import loadiris
 from sklearnmodelselection import traintestsplit
 from sklearnpipeline import Pipeline
X y  loadirisreturnXy True
Xtrain Xtest ytrain ytest  traintestsplitX y
stratifyy testsize07 randomstate42
nca  NeighborhoodComponentsAnalysisrandomstate42
knn  KNeighborsClassifiernneighbors3
ncapipe  Pipelinenca nca knn knn
ncapipefitXtrain ytrain
Pipeline
printncapipescoreXtest ytest
096190476
```

The plot shows decision boundaries for Nearest Neighbor Classification and Neighborhood Components Analysis classification on the iris dataset when training and scoring on only two features for visualisation purposes

Dimensionality reduction
NCA can be used to perform supervised dimensionality reduction The input data are projected onto a linear sub space consisting of the directions which minimize the NCA objective The desired dimensionality can be set us ing the parameter ncomponents For instance the following figure shows a comparison of dimensionality re duction with Principal Component Analysis sklearndecompositionPCA Linear Discriminant Analysis sklearndiscriminantanalysisLinearDiscriminantAnalysis and Neighborhood Component Analysis NeighborhoodComponentsAnalysis on the Digits dataset a dataset with size □□□□□□□□ 1797 and□□□□□□□□□ 64 The data set is split into a training and a test set of equal size then standardized For evalua tion the 3nearest neighbor classification accuracy is computed on the 2dimensional projected points found by each method Each data sample belongs to one of 10 classes
Examples
•Comparing Nearest Neighbors with and without Neighborhood Components Analysis
•Dimensionality Reduction with Neighborhood Components Analysis
•Manifold learning on handwritten digits Locally Linear Embedding Isomap
Mathematical formulation
The goal of NCA is to learn an optimal linear transformation matrix of size ncomponents nfeatures which maximises the sum over all samples □of the probability □□that□is correctly classified ie
arg max
□□−1∑
□0□□
with□nsamples and□□the probability of sample □being correctly classified according to a stochastic nearest neighbors rule in the learned embedded space

Mahalanobis distance
NCA can be seen as learning a squared Mahalanobis distance metric
□□□−□□2 □□−□□□□□□−□□
where □□□□is a symmetric positive semidefinite matrix of size nfeatures nfeatures
Implementation
This implementation follows what is explained in the original paper1 For the optimisation method it currently uses scipy’s LBFGSB with a full gradient computation at each iteration to avoid to tune the learning rate and provide stable learning
See the examples below and the docstring of NeighborhoodComponentsAnalysisfit for further informa tion
Complexity
Training
NCA stores a matrix of pairwise distances taking nsamples 2memory Time complexity depends on the number of iterations done by the optimisation algorithm However one can set the maximum number of itera tions with the argument maxiter For each iteration time complexity is Oncomponents x nsamples x minnsamples nfeatures
Transform
Here the transform operation returns □□□ therefore its time complexity equals ncomponents nfeatures nsamplestest There is no added space complexity in the operation
References
317 Gaussian Processes
Gaussian Processes GP are a generic supervised learning method designed to solve regression andprobabilistic classification problems
The advantages of Gaussian processes are
• The prediction interpolates the observations at least for regular kernels
• The prediction is probabilistic Gaussian so that one can compute empirical confidence intervals and decide based on those if one should refit online fitting adaptive fitting the prediction in some region of interest
• Versatile different kernels can be specified Common kernels are provided but it is also possible to specify custom kernels
1“Neighbourhood Components Analysis” Advances in Neural Information” J Goldberger G Hinton S Roweis R Salakhutdinov Advances in Neural Information Processing Systems V ol 17 May 2005 pp 513520

The disadvantages of Gaussian processes include
• They are not sparse ie they use the whole samplesfeatures information to perform the prediction
• They lose efficiency in high dimensional spaces – namely when the number of features exceeds a few dozens
Gaussian Process Regression GPR
TheGaussianProcessRegressor implements Gaussian processes GP for regression purposes For this the prior of the GP needs to be specified The prior mean is assumed to be constant and zero for normalizeyFalse or the training data's mean for normalizeyTrue The prior's covariance is specified by passing a kernel object The hyperparameters of the kernel are optimized during fitting of GaussianProcessRegressor by maximizing the log marginallikelihood LML based on the passed optimizer As the LML may have multiple local optima the optimizer can be started repeatedly by specifying nrestartsoptimizer The first run is always conducted starting from the initial hyperparameter values of the kernel subsequent runs are conducted from hyperparameter values that have been chosen randomly from the range of allowed values If the initial hyperparameters should be kept fixedNone can be passed as optimizer
The noise level in the targets can be specified by passing it via the parameter alpha either globally as a scalar or per datapoint Note that a moderate noise level can also be helpful for dealing with numeric issues during fitting as it is effectively implemented as Tikhonov regularization ie by adding it to the diagonal of the kernel matrix An alternative to specifying the noise level explicitly is to include a WhiteKernel component into the kernel which can estimate the global noise level from the data see example below
The implementation is based on Algorithm 21 of RW2006 In addition to the API of standard scikitlearn estimators GaussianProcessRegressor
• allows prediction without prior fitting based on the GP prior
• provides an additional method sampleyX which evaluates samples drawn from the GPR prior or poste rior at given inputs
• exposes a method logmarginallikelihoodtheta which can be used externally for other ways of selecting hyperparameters eg via Markov chain Monte Carlo
GPR examples
GPR with noiselevel estimation
This example illustrates that GPR with a sumkernel including a WhiteKernel can estimate the noise level of data An illustration of the logmarginallikelihood LML landscape shows that there exist two local maxima of LML
The first corresponds to a model with a high noise level and a large length scale which explains all variations in the data by noise
The second one has a smaller noise level and shorter length scale which explains most of the variation by the noise free functional relationship The second model has a higher likelihood however depending on the initial value for the hyperparameters the gradientbased optimization might also converge to the highnoise solution It is thus important to repeat the optimization several times for different initializations
Comparison of GPR and Kernel Ridge Regression
Both kernel ridge regression KRR and GPR learn a target function by employing internally the "kernel trick" KRR learns a linear function in the space induced by the respective kernel which corresponds to a nonlinear function in the original space The linear function in the kernel space is chosen based on the meansquared error loss with ridge regularization GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses

scikitlearn user guide Release 0213
31 Supervised learning 259

the observed training data to define a likelihood function Based on Bayes theorem a Gaussian posterior distribution over target functions is defined whose mean is used for prediction

A major difference is that GPR can choose the kernel’s hyperparameters based on gradientascent on the marginal likelihood function while KRR needs to perform a grid search on a crossvalidated loss function meansquared error loss A further difference is that GPR learns a generative probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions

The following figure illustrates both methods on an artificial dataset which consists of a sinusoidal target function and strong noise The figure compares the learned model of KRR and GPR based on a ExpSineSquared kernel which is suited for learning periodic functions The kernel’s hyperparameters control the smoothness lengthscale and periodicity of the kernel periodicity Moreover the noise level of the data is learned explicitly by GPR by an additional WhiteKernel component in the kernel and by the regularization parameter alpha of KRR

The figure shows that both methods learn reasonable models of the target function GPR correctly identifies the peri odicity of the function to be roughly 2□628 while KRR chooses the doubled periodicity 4□ Besides that GPR provides reasonable confidence bounds on the prediction which are not available for KRR A major difference between the two methods is the time required for fitting and predicting while fitting KRR is fast in principle the gridsearch for hyperparameter optimization scales exponentially with the number of hyperparameters “curse of dimensional ity” The gradientbased optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerable faster on this example with 3dimensional hyperparameter space The time for predicting is similar however generating the variance of the predictive distribution of GPR takes considerable longer than just predicting the mean

GPR on Mauna Loa CO2 data

This example is based on Section 543 of RW2006 It illustrates an example of complex kernel engineering and hyperparameter optimization using gradient ascent on the logmarginallikelihood The data consists of the monthly average atmospheric CO2 concentrations in parts per million by volume ppmv collected at the Mauna Loa Obser vatory in Hawaii between 1958 and 1997 The objective is to model the CO2 concentration as a function of the time t

The kernel is composed of several terms that are responsible for explaining different properties of the signal

• a long term smooth rising trend is to be explained by an RBF kernel The RBF kernel with a large lengthscale enforces this component to be smooth it is not enforced that the trend is rising which leaves this choice to the GP The specific lengthscale and the amplitude are free hyperparameters
• a seasonal component which is to be explained by the periodic ExpSineSquared kernel with a fixed periodicity of 1 year The lengthscale of this periodic component controlling its smoothness is a free parameter In order to allow decaying away from exact periodicity the product with an RBF kernel is taken The lengthscale of this RBF component controls the decay time and is a further free parameter
• smaller medium term irregularities are to be explained by a RationalQuadratic kernel component whose length scale and alpha parameter which determines the diffuseness of the lengthscales are to be determined Ac cording to RW2006 these irregularities can better be explained by a RationalQuadratic than an RBF kernel component probably because it can accommodate several lengthscales
• a “noise” term consisting of an RBF kernel contribution which shall explain the correlated noise components such as local weather phenomena and a WhiteKernel contribution for the white noise The relative amplitudes and the RBF’s length scale are further free parameters
Maximizing the logmarginallikelihood after subtracting the target’s mean yields the following kernel with an LML of 83214
3442RBFlengthscale418
3272RBFlengthscale180 ExpSineSquaredlengthscale144
periodicity1
04462RationalQuadraticalpha177 lengthscale0957
01972RBFlengthscale0138 WhiteKernelnoiselevel00336
Thus most of the target signal 344ppm is explained by a longterm rising trend lengthscale 418 years The periodic component has an amplitude of 327ppm a decay time of 180 years and a lengthscale of 144 The long decay time indicates that we have a locally very close to periodic seasonal component The correlated noise has an amplitude of 0197ppm with a length scale of 0138 years and a whitenoise contribution of 0197ppm Thus the overall noise level is very small indicating that the data can be very well explained by the model The figure shows also that the model makes very confident predictions until around 2015
Gaussian Process Classification GPC
TheGaussianProcessClassifier implements Gaussian processes GP for classification purposes more specifically for probabilistic classification where test predictions take the form of class probabilities GaussianPro cessClassifier places a GP prior on a latent function which is then squashed through a link function to obtain the probabilistic classification The latent function is a socalled nuisance function whose values are not observed and are not relevant by themselves Its purpose is to allow a convenient formulation of the model and is removed inte grated out during prediction GaussianProcessClassifier implements the logistic link function for which the integral cannot be computed analytically but is easily approximated in the binary case
In contrast to the regression setting the posterior of the latent function is not Gaussian even for a GP prior since a Gaussian likelihood is inappropriate for discrete class labels Rather a nonGaussian likelihood corresponding to the logistic link function logit is used GaussianProcessClassifier approximates the nonGaussian posterior with a Gaussian based on the Laplace approximation More details can be found in Chapter 3 of RW2006
The GP prior mean is assumed to be zero The prior’s covariance is specified by passing a kernel object The hyper parameters of the kernel are optimized during fitting of GaussianProcessRegressor by maximizing the logmarginal likelihood LML based on the passed optimizer As the LML may have multiple local optima the optimizer can be started repeatedly by specifying nrestartsoptimizer The first run is always conducted starting from the initial hyperparameter values of the kernel subsequent runs are conducted from hyperparameter values that have been chosen randomly from the range of allowed values If the initial hyperparameters should be kept fixed None can be passed as optimizer

scikitlearn user guide Release 0213
31 Supervised learning 263

GaussianProcessClassifier supports multiclass classification by performing either oneversusrest or one versusone based training and prediction In oneversusrest one binary Gaussian process classifier is fitted for each class which is trained to separate this class from the rest In “onevsone” one binary Gaussian process classifier is fitted for each pair of classes which is trained to separate these two classes The predictions of these binary predictors are combined into multiclass predictions See the section on multiclass classification for more details
In the case of Gaussian process classification “onevsone” might be computationally cheaper since it has to solve many problems involving only a subset of the whole training set rather than fewer problems on the whole dataset Since Gaussian process classification scales cubically with the size of the dataset this might be considerably faster How ever note that “onevsone” does not support predicting probability estimates but only plain predictions Moreover note thatGaussianProcessClassifier does not yet implement a true multiclass Laplace approximation in ternally but as discussed above is based on solving several binary classification tasks internally which are combined using oneversusrest or oneversusone
GPC examples
Probabilistic predictions with GPC
This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparam eters The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the hyperparameters corresponding to the maximum logmarginallikelihood LML
While the hyperparameters chosen by optimizing LML have a considerable larger LML they perform slightly worse according to the logloss on test data The figure shows that this is because they exhibit a steep change of the class probabilities at the class boundaries which is good but have predicted probabilities close to 05 far away from the class boundaries which is bad This undesirable effect is caused by the Laplace approximation used internally by GPC
The second figure shows the logmarginallikelihood for different choices of the kernel’s hyperparameters highlighting the two choices of the hyperparameters used in the first figure by black dots
Illustration of GPC on the XOR dataset
This example illustrates GPC on XOR data Compared are a stationary isotropic kernel RBF and a nonstationary kernel DotProduct On this particular dataset the DotProduct kernel obtains considerably better results be cause the classboundaries are linear and coincide with the coordinate axes In practice however stationary kernels such asRBF often obtain better results
Gaussian process classification GPC on iris dataset
This example illustrates the predicted probability of GPC for an isotropic and anisotropic RBF kernel on a two dimensional version for the irisdataset This illustrates the applicability of GPC to nonbinary classification The anisotropic RBF kernel obtains slightly higher logmarginallikelihood by assigning different lengthscales to the two feature dimensions
Kernels for Gaussian Processes
Kernels also called “covariance functions” in the context of GPs are a crucial ingredient of GPs which determine the shape of prior and posterior of the GP They encode the assumptions on the function being learned by defining the “similarity” of two datapoints combined with the assumption that similar datapoints should have similar target values Two categories of kernels can be distinguished stationary kernels depend only on the distance of two datapoints and not on their absolute values □□□ □□ □□□□ □□and are thus invariant to translations in the input space

scikitlearn user guide Release 0213
31 Supervised learning 265

while nonstationary kernels depend also on the specific values of the datapoints Stationary kernels can further be subdivided into isotropic and anisotropic kernels where isotropic kernels are also invariant to rotations in the input space For more details we refer to Chapter 4 of RW2006

Gaussian Process Kernel API

The main usage of a Kernel is to compute the GP's covariance between datapoints For this the method call of the kernel can be called This method can either be used to compute the "autocovariance" of all pairs of datapoints in a 2d array X or the "crosscovariance" of all combinations of datapoints of a 2d array X with datapoints in a 2d array Y The following identity holds true for all kernels k except for the WhiteKernel kX KX YX

If only the diagonal of the autocovariance is being used the method diag of a kernel can be called which is more computationally efficient than the equivalent call to call npdiagkX X kdiagX

Kernels are parameterized by a vector □of hyperparameters These hyperparameters can for instance control length scales or periodicity of a kernel see below All kernels support computing analytic gradients of the kernel's auto covariance with respect to □via settingevalgradientTrue in thecall method This gradient is used by the Gaussian process both regressor and classifier in computing the gradient of the logmarginallikelihood which in turn is used to determine the value of □ which maximizes the logmarginallikelihood via gradient ascent For each hyperparameter the initial value and the bounds need to be specified when creating an instance of the kernel The current value of □can be get and set via the property theta of the kernel object Moreover the bounds of the hyperparameters can be accessed by the property bounds of the kernel Note that both properties theta and bounds return logtransformed values of the internally used values since those are typically more amenable to gradientbased optimization The specification of each hyperparameter is stored in the form of an instance of Hyperparameter in the respective kernel Note that a kernel using a hyperparameter with name "x" must have the attributes selfx and selfxbounds

The abstract base class for all kernels is Kernel Kernel implements a similar interface as Estimator providing the methods getparams setparams andclone This allows setting kernel values also via meta estimators such as Pipeline orGridSearch Note that due to the nested structure of kernels by applying kernel operators see below the names of kernel parameters might become relatively complicated In general for a binary kernel operator parameters of the left operand are prefixed with k1 and parameters of the right operand with k2 An additional convenience method is clonewiththetatheta which returns a cloned version of the kernel

References
318 Cross decomposition
The cross decomposition module contains two main families of algorithms the partial least squares PLS and the canonical correlation analysis CCA
These families of algorithms are useful to find linear relations between two multivariate datasets the XandYarguments of the fit method are 2D arrays
Cross decomposition algorithms find the fundamental relations between two matrices X and Y They are latent variable approaches to modeling the covariance structures in these two spaces They will try to find the multidimensional direction in the X space that explains the maximum multidimensional variance direction in the Y space PLSregression is particularly suited when the matrix of predictors has more variables than observations and when there is multicollinearity among X values By contrast standard regression will fail in these cases
Classes included in this module are PLSRegressionPLSCanonical CCA andPLSSVD

319 Naive Bayes
Naive Bayes methods are a set of supervised learning algorithms based on applying Bayes' theorem with the "naive" assumption of conditional independence between every pair of features given the value of the class variable Bayes' theorem states the following relationship given class variable □and dependent feature vector □1through □□
□□□1 □ □ □□□□1 □ □□
□□1 □ □
Using the naive conditional independence assumption that
□□□□ □1 □ □−1 □□1 □ □ □□□□
for all □ this relationship is simplified to
□□□1 □ □ □□∏□
□1□□□□
□□1 □ □
Since □□1 □ □is constant given the input we can use the following classification rule
□□□1 □ □∝□□□∏
□1□□□□
⇓
□ arg max
□□□□∏
□1□□□□
and we can use Maximum A Posteriori MAP estimation to estimate □□and□□□□ the former is then the relative frequency of class □in the training set
The different naive Bayes classifiers differ mainly by the assumptions they make regarding the distribution of □□□ □
In spite of their apparently oversimplified assumptions naive Bayes classifiers have worked quite well in many real world situations famously document classification and spam filtering They require a small amount of training data to estimate the necessary parameters For theoretical reasons why naive Bayes works well and on which types of data it does see the references below
Naive Bayes learners and classifiers can be extremely fast compared to more sophisticated methods The decoupling of the class conditional feature distributions means that each distribution can be independently estimated as a one dimensional distribution This in turn helps to alleviate problems stemming from the curse of dimensionality
On the flip side although naive Bayes is known as a decent classifier it is known to be a bad estimator so the probability outputs from predictproba are not to be taken too seriously

The smoothing priors □≥0accounts for features not present in the learning samples and prevents zero probabilities in further computations Setting □ 1is called Laplace smoothing while □ 1is called Lidstone smoothing

Complement Naive Bayes

ComplementNB implements the complement naive Bayes CNB algorithm CNB is an adaptation of the standard multinomial naive Bayes MNB algorithm that is particularly suited for imbalanced data sets Specifically CNB uses statistics from the complement of each class to compute the model’s weights The inventors of CNB show empirically that the parameter estimates for CNB are more stable than those for MNB Further CNB regularly outperforms MNB often by a considerable margin on text classification tasks The procedure for calculating the weights is as follows

□□□□□∑
□□⁄□□□□
□∑
□□⁄□□∑
□□□□
□□□ log □□□
□□□□□□∑
□□□□

where the summations are over all documents □not in class □□□□is either the count or tfidf value of term □in document □□□is a smoothing hyperparameter like that found in MNB and □∑
□□□ The second normalization

addresses the tendency for longer documents to dominate parameter estimates in MNB The classification rule is
□ arg min
□∑
□□□□□□
ie a document is assigned to the class that is the poorest complement match

Bernoulli Naive Bayes
BernoulliNB implements the naive Bayes training and classification algorithms for data that is distributed according to multivariate Bernoulli distributions ie there may be multiple features but each one is assumed to be a binaryvalued Bernoulli boolean variable Therefore this class requires samples to be represented as binaryvalued feature vectors if handed any other kind of data a BernoulliNB instance may binarize its input depending on the binarize parameter
The decision rule for Bernoulli naive Bayes is based on
□□□□ □□□□□ 1−□□□1−□□
which differs from multinomial NB's rule in that it explicitly penalizes the nonoccurrence of a feature □that is an indicator for class □ where the multinomial variant would simply ignore a nonoccurring feature
In the case of text classification word occurrence vectors rather than word count vectors may be used to train and use this classifier BernoulliNB might perform better on some datasets especially those with shorter documents It is advisable to evaluate both models if time permits

Outofcore naive Bayes model fitting
Naive Bayes models can be used to tackle large scale classification problems for which the full training set might not fit in memory To handle this case MultinomialNB BernoulliNB andGaussianNB expose apartialfit method that can be used incrementally as done with other classifiers as demonstrated in Outofcore classification of text documents All naive Bayes classifiers support sample weighting
Contrary to the fit method the first call to partialfit needs to be passed the list of all the expected class labels
For an overview of available strategies in scikitlearn see also the outofcore learning documentation

Note Thepartialfit method call of naive Bayes models introduces some computational overhead It is recommended to use data chunk sizes that are as large as possible that is as the available RAM allows

3110 Decision Trees

Decision Trees DTs are a nonparametric supervised learning method used for classification andregression The goal is to create a model that predicts the value of a target variable by learning simple decision rules inferred from the data features

For instance in the example below decision trees learn from data to approximate a sine curve with a set of ifthenelse decision rules The deeper the tree the more complex the decision rules and the fitter the model

Some advantages of decision trees are

• Simple to understand and to interpret Trees can be visualised

• Requires little data preparation Other techniques often require data normalisation dummy variables need to be created and blank values to be removed Note however that this module does not support missing values

• The cost of using the tree ie predicting data is logarithmic in the number of data points used to train the tree

• Able to handle both numerical and categorical data Other techniques are usually specialised in analysing datasets that have only one type of variable See algorithms for more information

• Able to handle multioutput problems

• Uses a white box model If a given situation is observable in a model the explanation for the condition is easily explained by boolean logic By contrast in a black box model eg in an artificial neural network results may be more difficult to interpret

• Possible to validate a model using statistical tests That makes it possible to account for the reliability of the model

• Performs well even if its assumptions are somewhat violated by the true model from which the data were generated

The disadvantages of decision trees include

• Decisiontree learners can create overcomplex trees that do not generalise the data well This is called overfitting Mechanisms such as pruning not currently supported setting the minimum number of samples required at a leaf node or setting the maximum depth of the tree are necessary to avoid this problem

• Decision trees can be unstable because small variations in the data might result in a completely different tree being generated This problem is mitigated by using decision trees within an ensemble

• The problem of learning an optimal decision tree is known to be NPcomplete under several aspects of optimality and even for simple concepts Consequently practical decisiontree learning algorithms are based on heuristic algorithms such as the greedy algorithm where locally optimal decisions are made at each node Such algorithms cannot guarantee to return the globally optimal decision tree This can be mitigated by training multiple trees in an ensemble learner where the features and samples are randomly sampled with replacement

• There are concepts that are hard to learn because decision trees do not express them easily such as XOR parity or multiplexer problems

• Decision tree learners create biased trees if some classes dominate It is therefore recommended to balance the dataset prior to fitting with the decision tree

Classification

DecisionTreeClassifier is a class capable of performing multiclass classification on a dataset

As with other classifiers DecisionTreeClassifier takes as input two arrays an array X sparse or dense of sizensamples nfeatures holding the training samples and an array Y of integer values size nsamples holding the class labels for the training samples

```
 from sklearn import tree
X  0 0 1 1
Y  0 1
clf  treeDecisionTreeClassifier
clf  clffitX Y
```

After being fitted the model can then be used to predict the class of samples

```
clfpredict2 2
array1
```

Alternatively the probability of each class can be predicted which is the fraction of training samples of the same class in a leaf

```
clfpredictproba2 2
array0 1
```

DecisionTreeClassifier is capable of both binary where the labels are 1 1 classification and multiclass where the labels are 0   K1 classification

Using the Iris dataset we can construct a tree as follows

```
 from sklearndatasets import loadiris
 from sklearn import tree
iris  loadiris
clf  treeDecisionTreeClassifier
clf  clffitirisdata iristarget
```

Once trained you can plot the tree with the plottree function
treeplottreeclffitirisdata iristarget
We can also export the tree in Graphviz format using the exportgraphviz exporter If you use the conda package manager the graphviz binaries
and the python package can be installed with
conda install pythongraphviz
Alternatively binaries for graphviz can be downloaded from the graphviz project homepage and the Python wrapper installed from pypi with pip install graphviz
Below is an example graphviz export of the above tree trained on the entire iris dataset the results are saved in an output fileirispdf
```
 import graphviz
dotdata  treeexportgraphvizclf outfile None
graph  graphvizSourcedotdata
graphrenderiris
```
Theexportgraphviz exporter also supports a variety of aesthetic options including coloring nodes by their class or value for regression and using explicit variable and class names if desired Jupyter notebooks also render these plots inline automatically
```
dotdata  treeexportgraphvizclf outfile None
 featurenamesirisfeaturenames
 classnamesiristargetnames
 filledTrue rounded True
 specialcharacters True
graph  graphvizSourcedotdata
graph
```

Alternatively the tree can also be exported in textual format with the function exporttext This method doesn’t require the installation of external libraries and is more compact

```
 from sklearndatasets import loadiris
 from sklearntree import DecisionTreeClassifier
 from sklearntreeexport import exporttext
iris  loadiris
X  irisdata
y  iristarget
decisiontree  DecisionTreeClassifierrandomstate0 maxdepth2
decisiontree  decisiontreefitX y
r  exporttextdecisiontree featurenamesirisfeaturenames
printr
 petal width cm  080
  class 0
 petal width cm  080
  petal width cm  175
   class 1
  petal width cm  175
   class 2
```

Examples

•Plot the decision surface of a decision tree on the iris dataset

•Understanding the decision tree structure

Regression

Decision trees can also be applied to regression problems using the DecisionTreeRegressor class

As in the classification setting the fit method will take as argument arrays X and y only that in this case y is expected to have floating point values instead of integer values

```
 from sklearn import tree
X  0 0 2 2
y  05 25
clf  treeDecisionTreeRegressor
clf  clffitX y
clfpredict1 1
array05
```

Examples

•Decision Tree Regression

Multioutput problems

A multioutput problem is a supervised learning problem with several outputs to predict that is when Y is a 2d array of sizensamples noutputs

When there is no correlation between the outputs a very simple way to solve this kind of problem is to build n independent models ie one for each output and then to use those models to independently predict each one of the n outputs However because it is likely that the output values related to the same input are themselves correlated an often better way is to build a single model capable of predicting simultaneously all n outputs First it requires lower training time since only a single estimator is built Second the generalization accuracy of the resulting estimator may often be increased

With regard to decision trees this strategy can readily be used to support multioutput problems This requires the following changes

• Store n output values in leaves instead of 1

• Use splitting criteria that compute the average reduction across all n outputs

This module offers support for multioutput problems by implementing this strategy in both DecisionTreeClassifier andDecisionTreeRegressor If a decision tree is fit on an output array Y of size nsamples noutputs then the resulting estimator will

• Output noutput values upon predict

• Output a list of noutput arrays of class probabilities upon predictproba

The use of multioutput trees for regression is demonstrated in Multioutput Decision Tree Regression In this example the input X is a single real value and the outputs Y are the sine and cosine of X

The use of multioutput trees for classification is demonstrated in Face completion with a multioutput estimators In this example the inputs X are the pixels of the upper half of faces and the outputs Y are the pixels of the lower half of those faces

Examples

•Multioutput Decision Tree Regression

•Face completion with a multioutput estimators

Complexity
In general the run time cost to construct a balanced binary tree is □□□□□□□□□ □□□□□□□□□ log□□□□□□□□□ and query time□log□□□□□□□□□ Although the tree construction algorithm attempts to generate balanced trees they will not always be balanced Assuming that the subtrees remain approximately balanced the cost at each node consists of searching through □□□□□□□□□□ to find the feature that offers the largest reduction in entropy This has a cost of □□□□□□□□□□ □□□□□□□□□ log□□□□□□□□□ at each node leading to a total cost over the entire trees by summing the cost at each node of □□□□□□□□□□ □2
□□□□□□□ log□□□□□□□□□
Scikitlearn offers a more efficient implementation for the construction of decision trees A naive implementation as above would recompute the class label histograms for classification or the means for regression at for each new split point along a given feature Presorting the feature over all relevant samples and retaining a running la bel count will reduce the complexity at each node to □□□□□□□□□□ log□□□□□□□□□ which results in a total cost of □□□□□□□□□□ □□□□□□□□□ log□□□□□□□□□ This is an option for all tree based algorithms By default it is turned on for gradient boosting where in general it makes training faster but turned off for all other algorithms as it tends to slow down training when training deep trees
Tips on practical use
• Decision trees tend to overfit on data with a large number of features Getting the right ratio of samples to number of features is important since a tree with few samples in high dimensional space is very likely to overfit

• Consider performing dimensionality reduction PCA ICA orFeature selection beforehand to give your tree a better chance of finding features that are discriminative
•Understanding the decision tree structure will help in gaining more insights about how the decision tree makes predictions which is important for understanding the important features in the data
• Visualise your tree as you are training by using the export function Use maxdepth3 as an initial tree depth to get a feel for how the tree is fitting to your data and then increase the depth
• Remember that the number of samples required to populate the tree doubles for each additional level the tree grows to Use maxdepth to control the size of the tree to prevent overfitting
• Useminsamplessplit orminsamplesleaf to ensure that multiple samples inform every decision in the tree by controlling which splits will be considered A very small number will usually mean the tree will overfit whereas a large number will prevent the tree from learning the data Try minsamplesleaf5 as an initial value If the sample size varies greatly a float number can be used as percentage in these two parameters Whileminsamplessplit can create arbitrarily small leaves minsamplesleaf guarantees that each leaf has a minimum size avoiding lowvariance overfit leaf nodes in regression problems For classification with few classes minsamplesleaf1 is often the best choice
• Balance your dataset before training to prevent the tree from being biased toward the classes that are dominant Class balancing can be done by sampling an equal number of samples from each class or preferably by nor malizing the sum of the sample weights sampleweight for each class to the same value Also note that weightbased prepruning criteria such as minweightfractionleaf will then be less biased toward dominant classes than criteria that are not aware of the sample weights like minsamplesleaf
• If the samples are weighted it will be easier to optimize the tree structure using weightbased prepruning criterion such as minweightfractionleaf which ensure that leaf nodes contain at least a fraction of the overall sum of the sample weights
• All decision trees use npfloat32 arrays internally If training data is not in this format a copy of the dataset will be made
• If the input matrix X is very sparse it is recommended to convert to sparse cscmatrix before calling fit and sparsecsrmatrix before calling predict Training time can be orders of magnitude faster for a sparse matrix input compared to a dense matrix when features have zero values in most of the samples
Tree algorithms ID3 C45 C50 and CART
What are all the various decision tree algorithms and how do they differ from each other Which one is implemented in scikitlearn
ID3 Iterative Dichotomiser 3 was developed in 1986 by Ross Quinlan The algorithm creates a multiway tree finding for each node ie in a greedy manner the categorical feature that will yield the largest information gain for categorical targets Trees are grown to their maximum size and then a pruning step is usually applied to improve the ability of the tree to generalise to unseen data
C45 is the successor to ID3 and removed the restriction that features must be categorical by dynamically defining a discrete attribute based on numerical variables that partitions the continuous attribute value into a discrete set of intervals C45 converts the trained trees ie the output of the ID3 algorithm into sets of ifthen rules These accuracy of each rule is then evaluated to determine the order in which they should be applied Pruning is done by removing a rule’s precondition if the accuracy of the rule improves without it
C50 is Quinlan’s latest version release under a proprietary license It uses less memory and builds smaller rulesets than C45 while being more accurate
CART Classification and Regression Trees is very similar to C45 but it differs in that it supports numerical target variables regression and does not compute rule sets CART constructs binary trees using the feature and threshold that yield the largest information gain at each node

scikitlearn uses an optimised version of the CART algorithm however scikitlearn implementation does not support categorical variables for now

Mathematical formulation

3111 Ensemble methods
The goal of ensemble methods is to combine the predictions of several base estimators built with a given learning algorithm in order to improve generalizability robustness over a single estimator
Two families of ensemble methods are usually distinguished
• In averaging methods the driving principle is to build several estimators independently and then to average their predictions On average the combined estimator is usually better than any of the single base estimator because its variance is reduced
Examples Bagging methods Forests of randomized trees
• By contrast in boosting methods base estimators are built sequentially and one tries to reduce the bias of the combined estimator The motivation is to combine several weak models to produce a powerful ensemble
Examples AdaBoost Gradient Tree Boosting

Bagging metaestimator

In ensemble algorithms bagging methods form a class of algorithms which build several instances of a blackbox estimator on random subsets of the original training set and then aggregate their individual predictions to form a final prediction These methods are used as a way to reduce the variance of a base estimator eg a decision tree by introducing randomization into its construction procedure and then making an ensemble out of it In many cases bagging methods constitute a very simple way to improve with respect to a single model without making it necessary to adapt the underlying base algorithm As they provide a way to reduce overfitting bagging methods work best with strong and complex models eg fully developed decision trees in contrast with boosting methods which usually work best with weak models eg shallow decision trees

Bagging methods come in many flavours but mostly differ from each other by the way they draw random subsets of the training set

• When random subsets of the dataset are drawn as random subsets of the samples then this algorithm is known as Pasting B1999

• When samples are drawn with replacement then the method is known as Bagging B1996

• When random subsets of the dataset are drawn as random subsets of the features then the method is known as Random Subspaces H1998

• Finally when base estimators are built on subsets of both samples and features then the method is known as Random Patches LG2012

In scikitlearn bagging methods are offered as a unified BaggingClassifier metaestimator resp BaggingRegressor taking as input a userspecified base estimator along with parameters specifying the strategy to draw random subsets In particular maxsamples andmaxfeatures control the size of the subsets in terms of samples and features while bootstrap andbootstrapfeatures control whether samples and features are drawn with or without replacement When using a subset of the available samples the generalization accuracy can be estimated with the outofbag samples by setting oobscoreTrue As an example the snippet below illustrates how to instantiate a bagging ensemble of KNeighborsClassifier base estimators each built on random subsets of 50 of the samples and 50 of the features

```
 from sklearnensemble import BaggingClassifier
 from sklearnneighbors import KNeighborsClassifier
bagging  BaggingClassifierKNeighborsClassifier
 maxsamples05 maxfeatures05
```

Examples

•Single estimator versus bagging biasvariance decomposition

References

Forests of randomized trees

Thesklearnensemble module includes two averaging algorithms based on randomized decision trees the Ran domForest algorithm and the ExtraTrees method Both algorithms are perturbandcombine techniques B1998 specifically designed for trees This means a diverse set of classifiers is created by introducing randomness in the classifier construction The prediction of the ensemble is given as the averaged prediction of the individual classifiers

As other classifiers forest classifiers have to be fitted with two arrays a sparse or dense array X of size nsamples nfeatures holding the training samples and an array Y of size nsamples holding the target values class labels for the training samples

```
 from sklearnensemble import RandomForestClassifier
X  0 0 1 1
Y  0 1
clf  RandomForestClassifiernestimators10
clf  clffitX Y
```

Like decision trees forests of trees also extend to multioutput problems if Y is an array of size nsamples noutputs

Random Forests

In random forests see RandomForestClassifier andRandomForestRegressor classes each tree in the ensemble is built from a sample drawn with replacement ie a bootstrap sample from the training set Furthermore when splitting each node during the construction of a tree the best split is found either from all input features or a random subset of size maxfeatures See the parameter tuning guidelines for more details

The purpose of these two sources of randomness is to decrease the variance of the forest estimator Indeed individual decision trees typically exhibit high variance and tend to overfit The injected randomness in forests yield decision trees with somewhat decoupled prediction errors By taking an average of those predictions some errors can cancel out Random forests achieve a reduced variance by combining diverse trees sometimes at the cost of a slight increase in bias In practice the variance reduction is often significant hence yielding an overall better model

In contrast to the original publication B2001 the scikitlearn implementation combines classifiers by averaging their probabilistic prediction instead of letting each classifier vote for a single class

Extremely Randomized Trees

In extremely randomized trees see ExtraTreesClassifier andExtraTreesRegressor classes random ness goes one step further in the way splits are computed As in random forests a random subset of candidate features is used but instead of looking for the most discriminative thresholds thresholds are drawn at random for each candi date feature and the best of these randomlygenerated thresholds is picked as the splitting rule This usually allows to reduce the variance of the model a bit more at the expense of a slightly greater increase in bias

```
 from sklearnmodelselection import crossvalscore
 from sklearndatasets import makeblobs
 from sklearnensemble import RandomForestClassifier
 from sklearnensemble import ExtraTreesClassifier
 from sklearntree import DecisionTreeClassifier

scoresmean 0999
True
Parameters
The main parameters to adjust when using these methods is nestimators andmaxfeatures The former is the number of trees in the forest The larger the better but also the longer it will take to compute In addition note that results will stop getting significantly better beyond a critical number of trees The latter is the size of the random subsets of features to consider when splitting a node The lower the greater the reduction of variance but also the greater the increase in bias Empirical good default values are maxfeaturesNone always considering all features instead of a random subset for regression problems and maxfeaturessqrt using a random subset of sizesqrtnfeatures for classification tasks where nfeatures is the number of features in the data Good results are often achieved when setting maxdepthNone in combination with minsamplessplit2 ie when fully developing the trees Bear in mind though that these values are usually not optimal and might result in models that consume a lot of RAM The best parameter values should always be crossvalidated In addition note that in random forests bootstrap samples are used by default bootstrapTrue while the default strategy for extratrees is to use the whole dataset bootstrapFalse When using bootstrap sampling the generalization accuracy can be estimated on the left out or outofbag samples This can be enabled by setting oobscoreTrue
Note The size of the model with the default parameters is □□□□□□□ where □is the number of trees and □is the number of samples In order to reduce the size of the model you can change these parameters minsamplessplit maxleafnodes maxdepth andminsamplesleaf

Parallelization
Finally this module also features the parallel construction of the trees and the parallel computation of the predictions through the njobs parameter If njobsk then computations are partitioned into kjobs and run on kcores of the machine If njobs1 then all cores available on the machine are used Note that because of interprocess communication overhead the speedup might not be linear ie using kjobs will unfortunately not be ktimes as fast Significant speedup can still be achieved though when building a large number of trees or when building a single tree requires a fair amount of time eg on large datasets
Examples
•Plot the decision surfaces of ensembles of trees on the iris dataset
•Pixel importances with a parallel forest of trees
•Face completion with a multioutput estimators
References
• P Geurts D Ernst and L Wehenkel “Extremely randomized trees” Machine Learning 631 342 2006
Feature importance evaluation
The relative rank ie depth of a feature used as a decision node in a tree can be used to assess the relative importance of that feature with respect to the predictability of the target variable Features used at the top of the tree contribute to the final prediction decision of a larger fraction of the input samples The expected fraction of the samples they contribute to can thus be used as an estimate of the relative importance of the features In scikitlearn the fraction of samples a feature contributes to is combined with the decrease in impurity from splitting them to create a normalized estimate of the predictive power of that feature
Byaveraging the estimates of predictive ability over several randomized trees one can reduce the variance of such an estimate and use it for feature selection This is known as the mean decrease in impurity or MDI Refer to L2014 for more information on MDI and feature importance evaluation with Random Forests
The following example shows a colorcoded representation of the relative importances of each individual pixel for a face recognition task using a ExtraTreesClassifier model
In practice those estimates are stored as an attribute named featureimportances on the fitted model This is an array with shape nfeatures whose values are positive and sum to 10 The higher the value the more important is the contribution of the matching feature to the prediction function
Examples
•Pixel importances with a parallel forest of trees
•Feature importances with forests of trees

Totally Random Trees Embedding
RandomTreesEmbedding implements an unsupervised transformation of the data Using a forest of completely random trees RandomTreesEmbedding encodes the data by the indices of the leaves a data point ends up in This index is then encoded in a oneofK manner leading to a high dimensional sparse binary coding This coding can be computed very efficiently and can then be used as a basis for other learning tasks The size and sparsity of the code can be influenced by choosing the number of trees and the maximum depth per tree For each tree in the ensemble the coding contains one entry of one The size of the coding is at most nestimators 2maxdepth the maximum number of leaves in the forest
As neighboring data points are more likely to lie within the same leaf of a tree the transformation performs an implicit nonparametric density estimation
Examples
•Hashing feature transformation using Totally Random Trees
•Manifold learning on handwritten digits Locally Linear Embedding Isomap compares nonlinear dimen sionality reduction techniques on handwritten digits
•Feature transformations with ensembles of trees compares supervised and unsupervised tree based feature transformations
See also
Manifold learning techniques can also be useful to derive nonlinear representations of feature space also these ap proaches focus also on dimensionality reduction

AdaBoost
The module sklearnensemble includes the popular boosting algorithm AdaBoost introduced in 1995 by Freund and Schapire FS1995
The core principle of AdaBoost is to fit a sequence of weak learners ie models that are only slightly better than random guessing such as small decision trees on repeatedly modified versions of the data The predictions from all of them are then combined through a weighted majority vote or sum to produce the final prediction The data modifications at each socalled boosting iteration consist of applying weights □1□2 □□to each of the training samples Initially those weights are all set to □□ 1□ so that the first step simply trains a weak learner on the original data For each successive iteration the sample weights are individually modified and the learning algorithm is reapplied to the reweighted data At a given step those training examples that were incorrectly predicted by the boosted model induced at the previous step have their weights increased whereas the weights are decreased for those that were predicted correctly As iterations proceed examples that are difficult to predict receive everincreasing influence Each subsequent weak learner is thereby forced to concentrate on the examples that are missed by the previous ones in the sequence HTF
AdaBoost can be used both for classification and regression problems
• For multiclass classification AdaBoostClassifier implements AdaBoostSAMME and AdaBoost SAMMER ZZRH2009
• For regression AdaBoostRegressor implements AdaBoostR2 D1997
Usage
The following example shows how to fit an AdaBoost classifier with 100 weak learners
```
 from sklearnmodelselection import crossvalscore
 from sklearndatasets import loadiris
 from sklearnensemble import AdaBoostClassifier
```

iris loadiris
clf AdaBoostClassifiernestimators100
scores crossvalscoreclf irisdata iristarget cv5
scoresmean
09
The number of weak learners is controlled by the parameter nestimators Thelearningrate parameter controls the contribution of the weak learners in the final combination By default weak learners are decision stumps Different weak learners can be specified through the baseestimator parameter The main parameters to tune to obtain good results are nestimators and the complexity of the base estimators eg its depth maxdepth or minimum required number of samples to consider a split minsamplessplit
Examples
•Discrete versus Real AdaBoost compares the classification error of a decision stump decision tree and a boosted decision stump using AdaBoostSAMME and AdaBoostSAMMER
•Multiclass AdaBoosted Decision Trees shows the performance of AdaBoostSAMME and AdaBoost SAMMER on a multiclass problem
•Twoclass AdaBoost shows the decision boundary and decision function values for a nonlinearly separable twoclass problem using AdaBoostSAMME
•Decision Tree Regression with AdaBoost demonstrates regression with the AdaBoostR2 algorithm

Gradient Tree Boosting
Gradient Tree Boosting or Gradient Boosted Regression Trees GBRT is a generalization of boosting to arbitrary differentiable loss functions GBRT is an accurate and effective offtheshelf procedure that can be used for both regression and classification problems Gradient Tree Boosting models are used in a variety of areas including Web search ranking and ecology
The advantages of GBRT are
• Natural handling of data of mixed type heterogeneous features
• Predictive power
• Robustness to outliers in output space via robust loss functions
The disadvantages of GBRT are
• Scalability due to the sequential nature of boosting it can hardly be parallelized
The module sklearnensemble provides methods for both classification and regression via gradient boosted regression trees
Note Scikitlearn 021 introduces two new experimental implementation of gradient boosting trees namely HistGradientBoostingClassifier andHistGradientBoostingRegressor inspired by Light
GBM These fast estimators first bin the input samples Xinto integervalued bins typically 256 bins which tremendously reduces the number of splitting points to consider and allow the algorithm to leverage integerbased data structures histograms instead of relying on sorted continuous values

The new histogrambased estimators can be orders of magnitude faster than their continuous counterparts when the number of samples is larger than tens of thousands of samples The API of these new estimators is slightly different and some of the features from GradientBoostingClassifier andGradientBoostingRegressor are not yet supported

These new estimators are still experimental for now their predictions and their API might change without any deprecation cycle To use them you need to explicitly import enablehistgradientboosting

```
 explicitly require this experimental feature
 from sklearnexperimental import enablehistgradientboosting  noqa
 now you can import normally from ensemble
 from sklearnensemble import HistGradientBoostingClassifier
```

The following guide focuses on GradientBoostingClassifier andGradientBoostingRegressor only which might be preferred for small sample sizes since binning may lead to split points that are too approxi mate in this setting

Classification

GradientBoostingClassifier supports both binary and multiclass classification The following example shows how to fit a gradient boosting classifier with 100 decision stumps as weak learners

```
 from sklearndatasets import makehastie102
 from sklearnensemble import GradientBoostingClassifier
X y  makehastie102randomstate0

0913

The number of weak learners ie regression trees is controlled by the parameter nestimators The size of each treecan be controlled either by setting the tree depth via maxdepth or by setting the number of leaf nodes via maxleafnodes Thelearningrate is a hyperparameter in the range 00 10 that controls overfitting via shrinkage

Note Classification with more than 2 classes requires the induction of nclasses regression trees at each iteration thus the total number of induced trees equals nclasses nestimators For datasets with a large number of classes we strongly recommend to use RandomForestClassifier as an alternative to GradientBoostingClassifier

Regression

GradientBoostingRegressor supports a number of different loss functions for regression which can be speci fied via the argument loss the default loss function for regression is least squares ls

```
 import numpy as np
 from sklearnmetrics import meansquarederror
 from sklearndatasets import makefriedman1
```

```
 from sklearnensemble import GradientBoostingRegressor
X y  makefriedman1nsamples1200 randomstate0 noise10
Xtrain Xtest  X200 X200
ytrain ytest  y200 y200
est  GradientBoostingRegressornestimators100 learningrate01
 maxdepth1 randomstate0 losslsfitXtrain ytrain
meansquarederrorytest estpredictXtest
500
```
The figure below shows the results of applying GradientBoostingRegressor with least squares loss and 500 base learners to the Boston house price dataset sklearndatasetsloadboston The plot on the left shows the train and test error at each iteration The train error at each iteration is stored in the trainscore attribute of the gradient boosting model The test error at each iterations can be obtained via the stagedpredict method which returns a generator that yields the predictions at each stage Plots like these can be used to determine the optimal number of trees ie nestimators by early stopping The plot on the right shows the feature importances which can be obtained via the featureimportances property

Examples

- Gradient Boosting regression
- Gradient Boosting OutofBag estimates

Fitting additional weaklearners

BothGradientBoostingRegressor andGradientBoostingClassifier support warmstartTrue which allows you to add more estimators to an already fitted model

```
  estsetparamsnestimators200 warmstart True set warmstart and new
‘→nr of trees
  estfitXtrain ytrain  fit additional 100 trees to est
meansquarederrorytest estpredictXtest
```

Controlling the tree size

The size of the regression tree base learners defines the level of variable interactions that can be captured by the gradient boosting model In general a tree of depth hcan capture interactions of order h There are two ways in which the size of the individual regression trees can be controlled

If you specify maxdepthh then complete binary trees of depth hwill be grown Such trees will have at most 2hleaf nodes and 2h 1 split nodes

Alternatively you can control the tree size by specifying the number of leaf nodes via the parameter maxleafnodes In this case trees will be grown using bestfirst search where nodes with the highest improve ment in impurity will be expanded first A tree with maxleafnodesk hask 1 split nodes and thus can model interactions of up to order maxleafnodes 1

We found that maxleafnodesk gives comparable results to maxdepthk1 but is significantly faster to train at the expense of a slightly higher training error The parameter maxleafnodes corresponds to the variable Jin the chapter on gradient boosting in F2001 and is related to the parameter interactiondepth in R’s gbm package where maxleafnodes interactiondepth 1

Mathematical formulation

GBRT considers additive models of the following form

□□ □∑
□1□□*h*□□

where *h*□□are the basis functions which are usually called weak learners in the context of boosting Gradient Tree Boosting uses decision trees of fixed size as weak learners Decision trees have a number of abilities that make them valuable for boosting namely the ability to handle data of mixed type and the ability to model complex functions

Similar to other boosting algorithms GBRT builds the additive model in a greedy fashion

□□□ □□−1□ □□*h*□□

where the newly added tree *h*□tries to minimize the loss □ given the previous ensemble □□−1

h□ arg min
h□∑
□1□□□ □□−1□□ *h*□□

The initial model □0is problem specific for leastsquares regression one usually chooses the mean of the target values

Note The initial model can also be specified via the init argument The passed object has to implement fit and predict

Gradient Boosting attempts to solve this minimization problem numerically via steepest descent The steepest descent direction is the negative gradient of the loss function evaluated at the current model □□−1which can be calculated for any differentiable loss function

□□□ □□−1□−□□□∑
□1∇□□□□ □□−1□□

Where the step length □□is chosen using line search

□□ arg min
□□∑
□1□□□ □□−1□□−□□□□□ □□−1□□
□□□−1□□

The algorithms for regression and classification only differ in the concrete loss function used

Loss Functions

The following loss functions are supported and can be specified using the parameter loss

• Regression
–Least squares ls The natural choice for regression due to its superior computational properties The initial model is given by the mean of the target values
–Least absolute deviation lad A robust loss function for regression The initial model is given by the median of the target values
–Huber huber Another robust loss function that combines least squares and least absolute deviation usealpha to control the sensitivity with regards to outliers see F2001 for more details
–Quantile quantile A loss function for quantile regression Use 0 alpha 1 to specify the quantile This loss function can be used to create prediction intervals see Prediction Intervals for Gradient Boosting Regression
• Classification
–Binomial deviance deviance The negative binomial loglikelihood loss function for binary classification provides probability estimates The initial model is given by the log oddsratio
–Multinomial deviance deviance The negative multinomial loglikelihood loss function for multi class classification with nclasses mutually exclusive classes It provides probability estimates The initial model is given by the prior probability of each class At each iteration nclasses regression trees have to be constructed which makes GBRT rather inefficient for data sets with a large number of classes
–Exponential loss exponential The same loss function as AdaBoostClassifier Less robust to mislabeled examples than deviance can only be used for binary classification

Regularization
Shrinkage
F2001 proposed a simple regularization strategy that scales the contribution of each weak learner by a factor □
□□□ □□−1□ □□□ℎ□□
The parameter □is also called the learning rate because it scales the step length the gradient descent procedure it can be set via the learningrate parameter
The parameter learningrate strongly interacts with the parameter nestimators the number of weak learn
ers to fit Smaller values of learningrate require larger numbers of weak learners to maintain a constant training error Empirical evidence suggests that small values of learningrate favor better test error HTF2009 recom
mend to set the learning rate to a small constant eg learningrate 01 and choose nestimators by
early stopping For a more detailed discussion of the interaction between learningrate andnestimators
see R2007
Subsampling
F1999 proposed stochastic gradient boosting which combines gradient boosting with bootstrap averaging bagging At each iteration the base classifier is trained on a fraction subsample of the available training data The subsample is drawn without replacement A typical value of subsample is 05
The figure below illustrates the effect of shrinkage and subsampling on the goodnessoffit of the model We can clearly see that shrinkage outperforms noshrinkage Subsampling with shrinkage can further increase the accuracy of the model Subsampling without shrinkage on the other hand does poorly
Another strategy to reduce the variance is by subsampling the features analogous to the random splits in RandomForestClassifier The number of subsampled features can be controlled via the maxfeatures parameter

Note Using a small maxfeatures value can significantly decrease the runtime
Stochastic gradient boosting allows to compute outofbag estimates of the test deviance by computing the improvement in deviance on the examples that are not included in the bootstrap sample ie the outofbag examples The improvements are stored in the attribute oobimprovement oobimprovementi holds the improvement in terms of the loss on the OOB samples if you add the ith stage to the current predictions Outofbag estimates can be used for model selection for example to determine the optimal number of iterations OOB estimates are usually very pessimistic thus we recommend to use crossvalidation instead and only use OOB if crossvalidation is too time consuming
Examples
•Gradient Boosting regularization
•Gradient Boosting OutofBag estimates
•OOB Errors for Random Forests
Interpretation
Individual decision trees can be interpreted easily by simply visualizing the tree structure Gradient boosting models however comprise hundreds of regression trees thus they cannot be easily interpreted by visual inspection of the individual trees Fortunately a number of techniques have been proposed to summarize and interpret gradient boosting models
Feature importance
Often features do not contribute equally to predict the target response in many situations the majority of the features are in fact irrelevant When interpreting a model the first question usually is what are those important features and how do they contributing in predicting the target response
Individual decision trees intrinsically perform feature selection by selecting appropriate split points This information can be used to measure the importance of each feature the basic idea is the more often a feature is used in the split points of a tree the more important that feature is This notion of importance can be extended to decision tree ensembles by simply averaging the feature importance of each tree see Feature importance evaluation for more details
The feature importance scores of a fit gradient boosting model can be accessed via the featureimportances property

```

Examples

•Gradient Boosting regression
Voting Classifier
The idea behind the VotingClassifier is to combine conceptually different machine learning classifiers and use a majority vote or the average predicted probabilities soft vote to predict the class labels Such a classifier can be useful for a set of equally well performing model in order to balance out their individual weaknesses
Majority Class Labels MajorityHard Voting
In majority voting the predicted class label for a particular sample is the class label that represents the majority mode of the class labels predicted by each individual classifier
Eg if the prediction for a given sample is
• classifier 1 class 1
• classifier 2 class 1
• classifier 3 class 2
the V otingClassifier with votinghard would classify the sample as “class 1” based on the majority class label
In the cases of a tie the VotingClassifier will select the class based on the ascending sort order Eg in the following scenario
• classifier 1 class 2
• classifier 2 class 1
the class label 1 will be assigned to the sample
Usage
The following example shows how to fit the majority rule classifier

```
 from sklearn import datasets
 from sklearnmodelselection import crossvalscore
 from sklearnlinearmodel import LogisticRegression
 from sklearnnaivebayes import GaussianNB
 from sklearnensemble import RandomForestClassifier
 from sklearnensemble import VotingClassifier

‘→label
Accuracy 095  004 Logistic Regression
Accuracy 094  004 Random Forest
Accuracy 091  004 naive Bayes
Accuracy 095  004 Ensemble
```
Weighted Average Probabilities Soft Voting

In contrast to majority voting hard voting soft voting returns the class label as argmax of the sum of predicted probabilities

Specific weights can be assigned to each classifier via the weights parameter When weights are provided the predicted class probabilities for each classifier are collected multiplied by the classifier weight and averaged The final class label is then derived from the class label with the highest average probability

To illustrate this with a simple example let’s assume we have 3 classifiers and a 3class classification problems where we assign equal weights to all classifiers w11 w21 w31

The weighted average probabilities for a sample would then be calculated as follows

```
classifier class 1 class 2 class 3
classifier 1 w1  02 w1  05 w1  03
classifier 2 w2  06 w2  03 w2  01
classifier 3 w3  03 w3  04 w3  03
weighted average 037 04 023
```

Here the predicted class label is 2 since it has the highest average probability

The following example illustrates how the decision regions may change when a soft VotingClassifier is used based on an linear Support Vector Machine a Decision Tree and a Knearest neighbor classifier

3112 Multiclass and multilabel algorithms
Warning All classifiers in scikitlearn do multiclass classification outofthebox You don’t need to use the sklearnmulticlass module unless you want to experiment with different multiclass strategies
Thesklearnmulticlass module implements metaestimators to solvemulticlass andmultilabel classification problems by decomposing such problems into binary classification problems Multitarget regression is also supported
•Multiclass classification means a classification task with more than two classes eg classify a set of images of fruits which may be oranges apples or pears Multiclass classification makes the assumption that each sample is assigned to one and only one label a fruit can be either an apple or a pear but not both at the same time
•Multilabel classification assigns to each sample a set of target labels This can be thought as predicting properties of a datapoint that are not mutually exclusive such as topics that are relevant for a document A text might be about any of religion politics finance or education at the same time or none of these
•Multioutput regression assigns each sample a set of target values This can be thought of as predicting several properties for each datapoint such as wind direction and magnitude at a certain location

•Multioutputmulticlass classification andmultitask classification means that a single estimator has to handle several joint classification tasks This is both a generalization of the multilabel classification task which only considers binary classification as well as a generalization of the multiclass classification task The output format is a 2d numpy array or sparse matrix
The set of labels can be different for each output variable For instance a sample could be assigned “pear” for an output variable that takes possible values in a finite set of species such as “pear” “apple” and “blue” or “green” for a second output variable that takes possible values in a finite set of colors such as “green” “red” “blue” “yellow”
This means that any classifiers handling multioutput multiclass or multitask classification tasks support the multilabel classification task as a special case Multitask classification is similar to the multioutput classifica tion task with different model formulations For more information see the relevant estimator documentation
All scikitlearn classifiers are capable of multiclass classification but the metaestimators offered by sklearn multiclass permit changing the way they handle more than two classes because this may have an effect on classifier performance either in terms of generalization error or required computational resources
Below is a summary of the classifiers supported by scikitlearn grouped by strategy you don’t need the metaestimators in this class if you’re using one of these unless you want custom multiclass behavior

Warning At present no metric in sklearnmetrics supports the multioutputmulticlass classification task
Multilabel classification format
In multilabel learning the joint set of binary classification tasks is expressed with label binary indicator array each sample is one row of a 2d array of shape nsamples nclasses with binary values the one ie the non zero elements corresponds to the subset of labels An array such as nparray1 0 0 0 1 1 0 0 0
represents label 0 in the first sample labels 1 and 2 in the second sample and no labels in the third sample
Producing multilabel data as a list of sets of labels may be more intuitive The MultiLabelBinarizer transformer can be used to convert between a collection of collections of labels and the indicator format

```
 from sklearnpreprocessing import MultiLabelBinarizer
y  2 3 4 2 0 1 3 0 1 2 3 4 0 1 2
MultiLabelBinarizerfittransformy
array0 0 1 1 1
0 0 1 0 0
1 1 0 1 0
1 1 1 1 1
1 1 1 0 0
```
OneVsTheRest

This strategy also known as onevsall is implemented in OneVsRestClassifier The strategy consists in fitting one classifier per class For each classifier the class is fitted against all the other classes In addition to its computational efficiency only nclasses classifiers are needed one advantage of this approach is its interpretability Since each class is represented by one and only one classifier it is possible to gain knowledge about the class by inspecting its corresponding classifier This is the most commonly used strategy and is a fair default choice

Multiclass learning

Below is an example of multiclass learning using OvR

```
 from sklearn import datasets
 from sklearnmulticlass import OneVsRestClassifier
 from sklearnsvm import LinearSVC
iris  datasetsloadiris
X y  irisdata iristarget
OneVsRestClassifierLinearSVCrandomstate0fitX ypredictX
array0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
1 2 1 1 1 1 1 1 1 1 1 1 1 1 2 2 1 1 1 1 1 1 1 1
1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2
2 2 2 2 2 2 2 2 2 2 2 2 2 2 1 2 2 2 1 2 2 2 2 2
2 2 2 2 2 2 2 2 2 2 2 2
```

Multilabel learning

OneVsRestClassifier also supports multilabel classification To use this feature feed the classifier an indicator matrix in which cell i j indicates the presence of label j in sample i

Examples

•Multilabel classification

OneVsOne

OneVsOneClassifier constructs one classifier per pair of classes At prediction time the class which received the most votes is selected In the event of a tie among two classes with an equal number of votes it selects the class with the highest aggregate classification confidence by summing over the pairwise classification confidence levels computed by the underlying binary classifiers

Since it requires to fit nclasses nclasses 1 2 classifiers this method is usually slower than onevstherest due to its Onclasses2 complexity However this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with nsamples This is because each individual learning problem only involves a small subset of the data whereas with onevstherest the complete dataset is used nclasses times The decision function is the result of a monotonic transformation of the oneversusone classification

Multiclass learning

Below is an example of multiclass learning using OvO

```
 from sklearn import datasets
 from sklearnmulticlass import OneVsOneClassifier
 from sklearnsvm import LinearSVC
iris  datasetsloadiris
X y  irisdata iristarget
OneVsOneClassifierLinearSVCrandomstate0fitX ypredictX

ErrorCorrecting OutputCodes
Outputcode based strategies are fairly different from onevstherest and onevsone With these strategies each class is represented in a Euclidean space where each dimension can only be 0 or 1 Another way to put it is that each class is represented by a binary code an array of 0 and 1 The matrix which keeps track of the locationcode of each class is called the code book The code size is the dimensionality of the aforementioned space Intuitively each class should be represented by a code as unique as possible and a good code book should be designed to optimize classification accuracy In this implementation we simply use a randomlygenerated code book as advocated in3although more elaborate methods may be added in the future
At fitting time one binary classifier per bit in the code book is fitted At prediction time the classifiers are used to project new points in the class space and the class closest to the points is chosen
InOutputCodeClassifier thecodesize attribute allows the user to control the number of classifiers which will be used It is a percentage of the total number of classes
A number between 0 and 1 will require fewer classifiers than onevstherest In theory log2nclasses nclasses is sufficient to represent each class unambiguously However in practice it may not lead to good accuracy since log2nclasses is much smaller than nclasses
A number greater than 1 will require more classifiers than onevstherest In this case some classifiers will in theory correct for the mistakes made by other classifiers hence the name “errorcorrecting” In practice however this may not happen as classifier mistakes will typically be correlated The errorcorrecting output codes have a similar effect to bagging
Multiclass learning
Below is an example of multiclass learning using OutputCodes
```

Multioutput regression

Multioutput regression support can be added to any regressor with MultiOutputRegressor This strategy consists of fitting one regressor per target Since each target is represented by exactly one regressor it is possible to gain knowledge about the target by inspecting its corresponding regressor As MultiOutputRegressor fits one regressor per target it can not take advantage of correlations between targets

Below is an example of multioutput regression

```
 from sklearndatasets import makeregression
 from sklearnmultioutput import MultiOutputRegressor
 from sklearnensemble import GradientBoostingRegressor

Multioutput classification

Multioutput classification support can be added to any classifier with MultiOutputClassifier This strategy consists of fitting one classifier per target This allows multiple target variable classifications The purpose of this class is to extend estimators to be able to estimate a series of target functions f1f2f3 fn that are trained on a single X predictor matrix to predict a series of responses y1y2y3 yn

Below is an example of multioutput classification

```
 from sklearndatasets import makeclassification
 from sklearnmultioutput import MultiOutputClassifier
 from sklearnensemble import RandomForestClassifier
 from sklearnutils import shuffle
 import numpy as np

Classifier Chain

Classifier chains see ClassifierChain are a way of combining a number of binary classifiers into a single multilabel model that is capable of exploiting correlations among targets

For a multilabel classification problem with N classes N binary classifiers are assigned an integer between 0 and N1 These integers define the order of models in the chain Each classifier is then fit on the available training data plus the true labels of the classes whose models were assigned a lower number

When predicting the true labels will not be available Instead the predictions of each model are passed on to the subsequent models in the chain to be used as features

Clearly the order of the chain is important The first model in the chain has no information about the other labels while the last model in the chain has features indicating the presence of all of the other labels In general one does not know the optimal ordering of the models in the chain so typically many randomly ordered chains are fit and their predictions are averaged together

References

Jesse Read Bernhard Pfahringer Geoff Holmes Eibe Frank “Classifier Chains for Multilabel Classifica tion” 2009

Regressor Chain

Regressor chains see RegressorChain is analogous to ClassifierChain as a way of combining a number of re gressions into a single multitarget model that is capable of exploiting correlations among targets

3113 Feature selection

The classes in the sklearnfeatureselection module can be used for feature selectiondimensionality re duction on sample sets either to improve estimators’ accuracy scores or to boost their performance on very high dimensional datasets

Removing features with low variance

VarianceThreshold is a simple baseline approach to feature selection It removes all features whose variance doesn’t meet some threshold By default it removes all zerovariance features ie features that have the same value in all samples

As an example suppose that we have a dataset with boolean features and we want to remove all features that are either one or zero on or off in more than 80 of the samples Boolean features are Bernoulli random variables and the variance of such variables is given by
Var□ □1−□
so we can select using the threshold 81 8
 from sklearnfeatureselection import VarianceThreshold
X 0 0 1 0 1 0 1 0 0 0 1 1 0 1 0 0 1 1
sel VarianceThresholdthreshold8 1 8
selfittransformX
array0 1
1 0
0 0
1 1
1 0
1 1
As expected VarianceThreshold has removed the first column which has a probability □ 56 8of containing a zero
Univariate feature selection
Univariate feature selection works by selecting the best features based on univariate statistical tests It can be seen as a preprocessing step to an estimator Scikitlearn exposes feature selection routines as objects that implement the transform method
•SelectKBest removes all but the □highest scoring features
•SelectPercentile removes all but a userspecified highest scoring percentage of features
• using common univariate statistical tests for each feature false positive rate SelectFpr false discovery rate SelectFdr or family wise error SelectFwe
•GenericUnivariateSelect allows to perform univariate feature selection with a configurable strategy
This allows to select the best univariate selection strategy with hyperparameter search estimator
For instance we can perform a □2test to the samples to retrieve only the two best features as follows
 from sklearndatasets import loadiris
 from sklearnfeatureselection import SelectKBest
 from sklearnfeatureselection import chi2
iris loadiris
X y irisdata iristarget
Xshape
150 4
Xnew SelectKBestchi2 k2fittransformX y
Xnewshape
150 2
These objects take as input a scoring function that returns univariate scores and pvalues or only scores for SelectKBest andSelectPercentile
• For regression fregression mutualinforegression
• For classification chi2 fclassif mutualinfoclassif

The methods based on Ftest estimate the degree of linear dependency between two random variables On the other hand mutual information methods can capture any kind of statistical dependency but being nonparametric they require more samples for accurate estimation
Feature selection with sparse data
If you use sparse data ie data represented as sparse matrices chi2 mutualinforegression mutualinfoclassif will deal with the data without making it dense
Warning Beware not to use a regression scoring function with a classification problem you will get useless results
Examples
•Univariate Feature Selection
•Comparison of Ftest and mutual information
Recursive feature elimination
Given an external estimator that assigns weights to features eg the coefficients of a linear model recursive feature elimination RFE is to select features by recursively considering smaller and smaller sets of features First the estimator is trained on the initial set of features and the importance of each feature is obtained either through a coef attribute or through a featureimportances attribute Then the least important features are pruned from current set of featuresThat procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached
RFECV performs RFE in a crossvalidation loop to find the optimal number of features
Examples
•Recursive feature elimination A recursive feature elimination example showing the relevance of pixels in a digit classification task
•Recursive feature elimination with crossvalidation A recursive feature elimination example with automatic tuning of the number of features selected with crossvalidation
Feature selection using SelectFromModel
SelectFromModel is a metatransformer that can be used along with any estimator that has a coef or featureimportances attribute after fitting The features are considered unimportant and removed if the corresponding coef orfeatureimportances values are below the provided threshold parameter Apart from specifying the threshold numerically there are builtin heuristics for finding a threshold using a string argument Available heuristics are “mean” “median” and float multiples of these like “01mean”
For examples on how it is to be used refer to the sections below

Examples
•Feature selection using SelectFromModel and LassoCV Selecting the two most important features from the Boston dataset without knowing the threshold beforehand
L1based feature selection
Linear models penalized with the L1 norm have sparse solutions many of their estimated coefficients are zero When the goal is to reduce the dimensionality of the data to use with another classifier they can be used along withfeatureselectionSelectFromModel to select the nonzero coefficients In particular sparse estimators useful for this purpose are the linearmodelLasso for regression and of linearmodel LogisticRegression andsvmLinearSVC for classification

```
 from sklearnsvm import LinearSVC
 from sklearndatasets import loadiris
 from sklearnfeatureselection import SelectFromModel
iris  loadiris
X y  irisdata iristarget
Xshape
150 4
lsvc  LinearSVCC001 penaltyl1 dual FalsefitX y
model  SelectFromModellsvc prefit True
Xnew  modeltransformX
Xnewshape
150 3
```

With SVMs and logisticregression the parameter C controls the sparsity the smaller C the fewer features selected With Lasso the higher the alpha parameter the fewer features selected
Examples
•Classification of text documents using sparse features Comparison of different algorithms for document classification including L1based feature selection
L1recovery and compressive sensing
For a good choice of alpha the Lasso can fully recover the exact set of nonzero variables using only few obser vations provided certain specific conditions are met In particular the number of samples should be “sufficiently large” or L1 models will perform at random where “sufficiently large” depends on the number of nonzero co efficients the logarithm of the number of features the amount of noise the smallest absolute value of nonzero coefficients and the structure of the design matrix X In addition the design matrix must display certain specific properties such as not being too correlated
There is no general rule to select an alpha parameter for recovery of nonzero coefficients It can by set by cross validation LassoCV orLassoLarsCV though this may lead to underpenalized models including a small number of nonrelevant variables is not detrimental to prediction score BIC LassoLarsIC tends on the oppo site to set high values of alpha
Reference Richard G Baraniuk “Compressive Sensing” IEEE Signal Processing Magazine 120 July 2007 http usersisristutlptaguiarCSnotespdf

Treebased feature selection
Treebased estimators see the sklearntree module and forest of trees in the sklearnensemble module
can be used to compute feature importances which in turn can be used to discard irrelevant features when coupled
with thesklearnfeatureselectionSelectFromModel metatransformer
```
 from sklearnensemble import ExtraTreesClassifier
 from sklearndatasets import loadiris
 from sklearnfeatureselection import SelectFromModel
iris  loadiris
X y  irisdata iristarget
Xshape
150 4
clf  ExtraTreesClassifiernestimators50
clf  clffitX y
clffeatureimportances
array 004 005 04 04
model  SelectFromModelclf prefit True
Xnew  modeltransformX
Xnewshape
150 2
```
Examples
•Feature importances with forests of trees example on synthetic data showing the recovery of the actually
meaningful features
•Pixel importances with a parallel forest of trees example on face recognition data
Feature selection as part of a pipeline
Feature selection is usually used as a preprocessing step before doing the actual learning The recommended way to
do this in scikitlearn is to use a sklearnpipelinePipeline
```
clf  Pipeline
featureselection SelectFromModelLinearSVCpenaltyl1
classification RandomForestClassifier

clffitX y
```
In this snippet we make use of a sklearnsvmLinearSVC coupled with sklearnfeatureselection
SelectFromModel to evaluate feature importances and select the most relevant features Then a sklearn
ensembleRandomForestClassifier is trained on the transformed output ie using only relevant features
You can perform similar operations with the other feature selection methods and also classifiers that provide a way to
evaluate feature importances of course See the sklearnpipelinePipeline examples for more details
3114 SemiSupervised
Semisupervised learning is a situation in which in your training data some of the samples are not labeled The semi
supervised estimators in sklearnsemisupervised are able to make use of this additional unlabeled data to
better capture the shape of the underlying data distribution and generalize better to new samples These algorithms
can perform well when we have a very small amount of labeled points and a large amount of unlabeled points

Unlabeled entries in y
It is important to assign an identifier to unlabeled points along with the labeled data when training the model with thefit method The identifier that this implementation uses is the integer value −1
Label Propagation
Label propagation denotes a few variations of semisupervised graph inference algorithms
A few features available in this model
• Can be used for classification and regression tasks
• Kernel methods to project data into alternate dimensional spaces
scikitlearn provides two label propagation models LabelPropagation andLabelSpreading Both work by constructing a similarity graph over all items in the input dataset
Fig 31 An illustration of labelpropagation the structure of unlabeled observations is consistent with the class structure and thus the class label can be propagated to the unlabeled observations of the training set
LabelPropagation andLabelSpreading differ in modifications to the similarity matrix that graph and the clamping effect on the label distributions Clamping allows the algorithm to change the weight of the true ground labeled data to some degree The LabelPropagation algorithm performs hard clamping of input labels which means 0 This clamping factor can be relaxed to say 02 which means that we will always retain 80 percent of our original label distribution but the algorithm gets to change its confidence of the distribution within 20 percent
LabelPropagation uses the raw similarity matrix constructed from the data with no modifications In contrast LabelSpreading minimizes a loss function that has regularization properties as such it is often more robust to noise The algorithm iterates on a modified version of the original graph and normalizes the edge weights by computing the normalized graph Laplacian matrix This procedure is also used in Spectral clustering
Label propagation models have two builtin kernel methods Choice of kernel effects both scalability and performance of the algorithms The following are available
• rbf exp−□□−□2 0□is specified by keyword gamma
• knn 1□′∈□□□ □□is specified by keyword nneighbors

The RBF kernel will produce a fully connected graph which is represented in memory by a dense matrix This matrix may be very large and combined with the cost of performing a full matrix multiplication calculation for each iteration of the algorithm can lead to prohibitively long running times On the other hand the KNN kernel will produce a much more memoryfriendly sparse matrix which can drastically reduce running times

Examples

•Decision boundary of label propagation versus SVM on the Iris dataset
•Label Propagation learning a complex structure
•Label Propagation digits Demonstrating performance
•Label Propagation digits active learning

3115 Isotonic regression

The classIsotonicRegression fits a nondecreasing function to data It solves the following problem

minimize∑
□□□□□−□□2
subject to □□□□ □1≤□2≤□□ □□□□

where each □□is strictly positive and each □□is an arbitrary real number It yields the vector which is composed of nondecreasing elements the closest in terms of mean squared error In practice this list of elements forms a function that is piecewise linear

3116 Probability calibration

When performing classification you often want not only to predict the class label but also obtain a probability of the respective label This probability gives you some kind of confidence on the prediction Some models can give you poor estimates of the class probabilities and some even do not support probability prediction The calibration module allows you to better calibrate the probabilities of a given model or to add support for probability prediction

Well calibrated classifiers are probabilistic classifiers for which the output of the predictproba method can be directly interpreted as a confidence level For instance a well calibrated binary classifier should classify the samples such that among the samples to which it gave a predictproba value close to 08 approximately 80 actually belong to the positive class The following plot compares how well the probabilistic predictions of different classifiers are calibrated

LogisticRegression returns well calibrated predictions by default as it directly optimizes logloss In contrast the other methods return biased probabilities with different biases per method

•GaussianNB tends to push probabilities to 0 or 1 note the counts in the histograms This is mainly because it makes the assumption that features are conditionally independent given the class which is not the case in this dataset which contains 2 redundant features

scikitlearn user guide Release 0213
31 Supervised learning 321

•RandomForestClassifier shows the opposite behavior the histograms show peaks at approximately 02 and 09 probability while probabilities close to 0 or 1 are very rare An explanation for this is given by NiculescuMizil and Caruana4 “Methods such as bagging and random forests that average predictions from a base set of models can have difficulty making predictions near 0 and 1 because variance in the underlying base models will bias predictions that should be near zero or one away from these values Because predictions are restricted to the interval 01 errors caused by variance tend to be onesided near zero and one For example if a model should predict p 0 for a case the only way bagging can achieve this is if all bagged trees predict zero If we add noise to the trees that bagging is averaging over this noise will cause some trees to predict values larger than 0 for this case thus moving the average prediction of the bagged ensemble away from 0 We observe this effect most strongly with random forests because the baselevel trees trained with random forests have relatively high variance due to feature subsetting” As a result the calibration curve also referred to as the reliability diagram Wilks 19955 shows a characteristic sigmoid shape indicating that the classifier could trust its “intuition” more and return probabilities closer to 0 or 1 typically

• Linear Support Vector Classification LinearSVC shows an even more sigmoid curve as the RandomForest Classifier which is typical for maximummargin methods compare NiculescuMizil and Caruana4 which focus on hard samples that are close to the decision boundary the support vectors

Two approaches for performing calibration of probabilistic predictions are provided a parametric approach based on Platt’s sigmoid model and a nonparametric approach based on isotonic regression sklearnisotonic Proba bility calibration should be done on new data not used for model fitting The class CalibratedClassifierCV uses a crossvalidation generator and estimates for each split the model parameter on the train samples and the cali bration of the test samples The probabilities predicted for the folds are then averaged Already fitted classifiers can be calibrated by CalibratedClassifierCV via the parameter cv”prefit” In this case the user has to take care manually that data for model fitting and calibration are disjoint

The following images demonstrate the benefit of probability calibration The first image present a dataset with 2 classes and 3 blobs of data The blob in the middle contains random samples of each class The probability for the samples in this blob should be 05

The following image shows on the data above the estimated probability using a Gaussian naive Bayes classifier without calibration with a sigmoid calibration and with a nonparametric isotonic calibration One can observe that the non parametric model provides the most accurate probability estimates for samples in the middle ie 05

The following experiment is performed on an artificial dataset for binary classification with 100000 samples 1000 of them are used for model fitting with 20 features Of the 20 features only 2 are informative and 10 are redundant The figure shows the estimated probabilities obtained with logistic regression a linear supportvector classifier SVC and linear SVC with both isotonic calibration and sigmoid calibration The Brier score is a metric which is a combi nation of calibration loss and refinement loss brierscoreloss reported in the legend the smaller the better Calibration loss is defined as the mean squared deviation from empirical probabilities derived from the slope of ROC segments Refinement loss can be defined as the expected optimal loss as measured by the area under the optimal cost curve

One can observe here that logistic regression is well calibrated as its curve is nearly diagonal Linear SVC’s calibration curve or reliability diagram has a sigmoid curve which is typical for an underconfident classifier In the case of LinearSVC this is caused by the margin property of the hinge loss which lets the model focus on hard samples that are close to the decision boundary the support vectors Both kinds of calibration can fix this issue and yield nearly identical results The next figure shows the calibration curve of Gaussian naive Bayes on the same data with both kinds of calibration and also without calibration

One can see that Gaussian naive Bayes performs very badly but does so in an other way than linear SVC While linear SVC exhibited a sigmoid calibration curve Gaussian naive Bayes’ calibration curve has a transposedsigmoid shape This is typical for an overconfident classifier In this case the classifier’s overconfidence is caused by the redundant features which violate the naive Bayes assumption of featureindependence

4Predicting Good Probabilities with Supervised Learning A NiculescuMizil R Caruana ICML 2005

5On the combination of forecast probabilities for consecutive precipitation periods Wea Forecasting 5 640–650 Wilks D S 1990a

scikitlearn user guide Release 0213
31 Supervised learning 325

scikitlearn user guide Release 0213
31 Supervised learning 327

Calibration of the probabilities of Gaussian naive Bayes with isotonic regression can fix this issue as can be seen from the nearly diagonal calibration curve Sigmoid calibration also improves the brier score slightly albeit not as strongly as the nonparametric isotonic calibration This is an intrinsic limitation of sigmoid calibration whose parametric form assumes a sigmoid rather than a transposedsigmoid curve The nonparametric isotonic calibration model however makes no such strong assumptions and can deal with either shape provided that there is sufficient calibration data In general sigmoid calibration is preferable in cases where the calibration curve is sigmoid and where there is limited calibration data while isotonic calibration is preferable for nonsigmoid calibration curves and in situations where large amounts of data are available for calibration

CalibratedClassifierCV can also deal with classification tasks that involve more than two classes if the base estimator can do so In this case the classifier is calibrated first for each class separately in an onevsrest fashion When predicting probabilities for unseen data the calibrated probabilities for each class are predicted separately As those probabilities do not necessarily sum to one a postprocessing is performed to normalize them

The next image illustrates how sigmoid calibration changes predicted probabilities for a 3class classification problem Illustrated is the standard 2simplex where the three corners correspond to the three classes Arrows point from the probability vectors predicted by an uncalibrated classifier to the probability vectors predicted by the same classifier after sigmoid calibration on a holdout validation set Colors indicate the true class of an instance red class 1 green class 2 blue class 3

The base classifier is a random forest classifier with 25 base estimators trees If this classifier is trained on all 800 training datapoints it is overly confident in its predictions and thus incurs a large logloss Calibrating an identical classifier which was trained on 600 datapoints with method’sigmoid’ on the remaining 200 datapoints reduces the confidence of the predictions ie moves the probability vectors from the edges of the simplex towards the center

scikitlearn user guide Release 0213
31 Supervised learning 329

This calibration results in a lower logloss Note that an alternative would have been to increase the number of base estimators which would have resulted in a similar decrease in logloss

3117 Neural network models supervised

Warning This implementation is not intended for largescale applications In particular scikitlearn offers no GPU support For much faster GPUbased implementations as well as frameworks offering much more flexibility to build deep learning architectures see Related Projects

Multilayer Perceptron

Multilayer Perceptron MLP is a supervised learning algorithm that learns a function □· □□→□□by training on a dataset where □is the number of dimensions for input and □is the number of dimensions for output Given a set of features □□1 □2 □ □and a target □ it can learn a nonlinear function approximator for either classification or regression It is different from logistic regression in that between the input and the output layer there can be one or more nonlinear layers called hidden layers Figure 1 shows a one hidden layer MLP with scalar output

Fig 32 Figure 1 One hidden layer MLP

The leftmost layer known as the input layer consists of a set of neurons □□□1 □2 □ □representing the input features Each neuron in the hidden layer transforms the values from the previous layer with a weighted linear sum mation □1□1□2□2□□□□ followed by a nonlinear activation function □· □→□ like the hyperbolic tan function The output layer receives the values from the last hidden layer and transforms them into output values

The module contains the public attributes coefs andintercepts coefs is a list of weight matrices where weight matrix at index represents the weights between layer and layer 1intercepts is a list of bias vectors where the vector at index represents the bias values added to layer 1

The advantages of Multilayer Perceptron are

• Capability to learn nonlinear models

• Capability to learn models in realtime online learning using partialfit

The disadvantages of Multilayer Perceptron MLP include

• MLP with hidden layers have a nonconvex loss function where there exists more than one local minimum Therefore different random weight initializations can lead to different validation accuracy

• MLP requires tuning a number of hyperparameters such as the number of hidden neurons layers and iterations

• MLP is sensitive to feature scaling

Please see Tips on Practical Use section that addresses some of these disadvantages

Classification

ClassMLPClassifier implements a multilayer perceptron MLP algorithm that trains using Backpropagation

MLP trains on two arrays array X of size nsamples nfeatures which holds the training samples represented as floating point feature vectors and array y of size nsamples which holds the target values class labels for the training samples

```
 from sklearnneuralnetwork import MLPClassifier
X  0 0 1 1
y  0 1
clf  MLPClassifiersolverlbfgs alpha1e5
 hiddenlayersizes5 2 randomstate1

maxiter200 momentum09 niternochange10
nesterovsmomentumTrue powert05 randomstate1
shuffleTrue solverlbfgs tol00001
validationfraction01 verboseFalse warmstartFalse
```

After fitting training the model can predict labels for new samples

```
clfpredict2 2 1 2
array1 0
```

MLP can fit a nonlinear model to the training data clfcoefs contains the weight matrices that constitute the model parameters

```
coefshape forcoefinclfcoefs
2 5 5 2 2 1
```

CurrentlyMLPClassifier supports only the CrossEntropy loss function which allows probability estimates by running the predictproba method

MLP trains using Backpropagation More precisely it trains using some form of gradient descent and the gradients are calculated using Backpropagation For classification it minimizes the CrossEntropy loss function giving a vector of probability estimates □□□per sample □

```
clfpredictproba2 2 1 2
array1967e04 999801
1967e04 999801
```

MLPClassifier supports multiclass classification by applying Softmax as the output function

Further the model supports multilabel classification in which a sample can belong to more than one class For each class the raw output passes through the logistic function Values larger or equal to 05 are rounded to 1 otherwise to 0 For a predicted output of a sample the indices where the value is 1represents the assigned classes of that sample

```
X  0 0 1 1

array0 1
```

See the examples below and the docstring of MLPClassifierfit for further information

Examples

•Compare Stochastic learning strategies for MLPClassifier

•Visualization of MLP weights on MNIST

Regression

ClassMLPRegressor implements a multilayer perceptron MLP that trains using backpropagation with no activa tion function in the output layer which can also be seen as using the identity function as activation function Therefore it uses the square error as the loss function and the output is a set of continuous values

MLPRegressor also supports multioutput regression in which a sample can have more than one target

Regularization

BothMLPRegressor andMLPClassifier use parameter alpha for regularization L2 regularization term which helps in avoiding overfitting by penalizing weights with large magnitudes Following plot displays varying decision function with value of alpha

See the examples below for further information
Examples
•Varying regularization in Multilayer Perceptron
Algorithms
MLP trains using Stochastic Gradient Descent Adam or LBFGS Stochastic Gradient Descent SGD updates pa
rameters using the gradient of the loss function with respect to a parameter that needs adaptation ie
□←□−□□□□□
□□□□□□□
□□
where □is the learning rate which controls the stepsize in the parameter space search □□□□ is the loss function used
for the network
More details can be found in the documentation of SGD
Adam is similar to SGD in a sense that it is a stochastic optimizer but it can automatically adjust the amount to update
parameters based on adaptive estimates of lowerorder moments
With SGD or Adam training supports online and minibatch learning
LBFGS is a solver that approximates the Hessian matrix which represents the secondorder partial derivative of a
function Further it approximates the inverse of the Hessian matrix to perform parameter updates The implementation
uses the Scipy version of LBFGS
If the selected solver is ‘LBFGS’ training does not support online nor minibatch learning

Complexity
Suppose there are □training samples □features □hidden layers each containing *h*neurons for simplicity and □
output neurons The time complexity of backpropagation is □□·□·*h*□·□·□ where □is the number of iterations
Since backpropagation has a high time complexity it is advisable to start with smaller number of hidden neurons and
few hidden layers for training
Mathematical formulation
Given a set of training examples □1 □1□2 □2 □□ □□where □□∈R□and□□∈01 a one hidden layer
one hidden neuron MLP learns the function □□ □2□□□
1□□1 □2where □1∈R□and□2 □1 □2∈Rare
model parameters □1 □2represent the weights of the input layer and hidden layer respectively and □1 □2represent
the bias added to the hidden layer and the output layer respectively □· □→□is the activation function set by
default as the hyperbolic tan It is given as
□□ □□−□−□
□□□−□
For binary classification □□passes through the logistic function □□ 1 1□−□to obtain output values between
zero and one A threshold set to 05 would assign samples of outputs larger or equal 05 to the positive class and the
rest to the negative class
If there are more than two classes □□itself would be a vector of size nclasses Instead of passing through logistic
function it passes through the softmax function which is written as
softmax □□exp□□
∑□
□1exp□□
where □□represents the □th element of the input to softmax which corresponds to class □ and □is the number of
classes The result is a vector containing the probabilities that sample □belong to each class The output is the class
with the highest probability
In regression the output remains as □□ therefore output activation function is just the identity function
MLP uses different loss functions depending on the problem type The loss function for classification is CrossEntropy
which in binary case is given as
□□□□ □ □ □ −□ln □−1−□ ln 1−□ □□2
2
where □□2
2is an L2regularization term aka penalty that penalizes complex models and □ 0is a nonnegative
hyperparameter that controls the magnitude of the penalty
For regression MLP uses the Square Error loss function written as
□□□□ □ □ □ 1
2□−□2
2□
2□2
2
Starting from initial random weights multilayer perceptron MLP minimizes the loss function by repeatedly updating
these weights After computing the loss a backward pass propagates it from the output layer to the previous layers
providing each weight parameter with an update value meant to decrease the loss
In gradient descent the gradient ∇□□□□ □of the loss with respect to the weights is computed and deducted from □
More formally this is expressed as
□□1□□−□∇□□□□□
□
where □is the iteration step and □is the learning rate with a value larger than 0
The algorithm stops when it reaches a preset maximum number of iterations or when the improvement in loss is below
a certain small number

Tips on Practical Use
• Multilayer Perceptron is sensitive to feature scaling so it is highly recommended to scale your data For example scale each attribute on the input vector X to 0 1 or 1 1 or standardize it to have mean 0 and variance 1 Note that you must apply the same scaling to the test set for meaningful results You can use StandardScaler for standardization
```
 from sklearnpreprocessing import StandardScaler
scaler  StandardScaler
 Dont cheat  fit only on training data
scalerfitXtrain
Xtrain  scalertransformXtrain
 apply same transformation to test data
Xtest  scalertransformXtest
```
An alternative and recommended approach is to use StandardScaler in aPipeline
• Finding a reasonable regularization parameter □is best done using GridSearchCV usually in the range 100 nparange1 7
• Empirically we observed that LBFGS converges faster and with better solutions on small datasets For relatively large datasets however Adam is very robust It usually converges quickly and gives pretty good performance Stochastic Gradient Descent with momentum or nesterov's momentum on the other hand can perform better than those two algorithms if learning rate is correctly tuned
More control with warmstart
If you want more control over stopping criteria or learning rate in SGD or want to do additional monitoring using warmstartTrue andmaxiter1 and iterating yourself can be helpful
```
X  0 0 1 1
y  0 1
clf  MLPClassifierhiddenlayersizes15 randomstate1 maxiter1 warm
‹→startTrue
 for iinrange10
 clffitX y
  additional monitoring  inspection
```

32 Unsupervised learning
321 Gaussian mixture models
sklearnmixture is a package which enables one to learn Gaussian Mixture Models diagonal spherical tied and full covariance matrices supported sample them and estimate them from data Facilities to help determine the appropriate number of components are also provided
Fig 33 Twocomponent Gaussian mixture model data points and equiprobability surfaces of the model
A Gaussian mixture model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters One can think of mixture models as generalizing kmeans clustering to incorporate information about the covariance structure of the data as well as the centers of the latent Gaussians
Scikitlearn implements different classes to estimate Gaussian mixture models that correspond to different estimation strategies detailed below
Gaussian Mixture
TheGaussianMixture object implements the expectationmaximization EM algorithm for fitting mixtureof Gaussian models It can also draw confidence ellipsoids for multivariate models and compute the Bayesian Information Criterion to assess the number of clusters in the data A GaussianMixturefit method is provided that learns a Gaussian Mixture Model from train data Given test data it can assign to each sample the Gaussian it mostly probably belong to using the GaussianMixturepredict method
TheGaussianMixture comes with different options to constrain the covariance of the difference classes estimated spherical diagonal tied or full covariance
Examples
• See GMM covariances for an example of using the Gaussian mixture as clustering on the iris dataset
• See Density Estimation for a Gaussian mixture for an example on plotting the density estimation

Pros and cons of class GaussianMixture
Pros
Speed It is the fastest algorithm for learning mixture models
Agnostic As this algorithm maximizes only the likelihood it will not bias the means towards zero or bias the cluster sizes to have specific structures that might or might not apply
Cons
Singularities When one has insufficiently many points per mixture estimating the covariance matrices becomes difficult and the algorithm is known to diverge and find solutions with infinite likelihood unless one regularizes the covariances artificially
Number of components This algorithm will always use all the components it has access to needing heldout data or information theoretical criteria to decide how many components to use in the absence of external cues
Selecting the number of components in a classical Gaussian Mixture Model
The BIC criterion can be used to select the number of components in a Gaussian Mixture in an efficient way In theory it recovers the true number of components only in the asymptotic regime ie if much data is available and assuming

that the data was actually generated iid from a mixture of Gaussian distribution Note that using a Variational Bayesian Gaussian mixture avoids the specification of the number of components for a Gaussian mixture model

Examples

• See Gaussian Mixture Model Selection for an example of model selection performed with classical Gaussian mixture

Estimation algorithm Expectationmaximization

The main difficulty in learning Gaussian mixture models from unlabeled data is that it is one usually doesn't know which points came from which latent component if one has access to this information it gets very easy to fit a separate Gaussian distribution to each set of points Expectationmaximization is a wellfounded statistical algorithm to get around this problem by an iterative process First one assumes random components randomly centered on data points learned from kmeans or even just normally distributed around the origin and computes for each point a probability of being generated by each component of the model Then one tweaks the parameters to maximize the likelihood of the data given those assignments Repeating this process is guaranteed to always converge to a local optimum

Variational Bayesian Gaussian Mixture

TheBayesianGaussianMixture object implements a variant of the Gaussian mixture model with variational inference algorithms The API is similar as the one defined by GaussianMixture

Estimation algorithm variational inference

Variational inference is an extension of expectationmaximization that maximizes a lower bound on model evidence including priors instead of data likelihood The principle behind variational methods is the same as expectation maximization that is both are iterative algorithms that alternate between finding the probabilities for each point to

be generated by each mixture and fitting the mixture to these assigned points but variational methods add regular ization by integrating information from prior distributions This avoids the singularities often found in expectation maximization solutions but introduces some subtle biases to the model Inference is often notably slower but not usually as much so as to render usage unpractical

Due to its Bayesian nature the variational algorithm needs more hyper parameters than expectationmaximization the most important of these being the concentration parameter weightconcentrationprior Specifying a low value for the concentration prior will make the model put most of the weight on few components set the remain ing components weights very close to zero High values of the concentration prior will allow a larger number of components to be active in the mixture

The parameters implementation of the BayesianGaussianMixture class proposes two types of prior for the weights distribution a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components called the Stickbreaking representation The number of components actually used almost always depends on the data

The next figure compares the results obtained for the different type of the weight concentration prior parameter weightconcentrationpriortype for different values of weightconcentrationprior Here we can see the value of the weightconcentrationprior parameter has a strong impact on the effective number of active components obtained We can also notice that large values for the concentration weight prior lead to more uniform weights when the type of prior is ‘dirichletdistribution’ while this is not necessarily the case for the ‘dirichletprocess’ type used by default

The examples below compare Gaussian mixture models with a fixed number of components to the variational Gaus sian mixture models with a Dirichlet process prior Here a classical Gaussian mixture is fitted with 5 components on a dataset composed of 2 clusters We can see that the variational Gaussian mixture with a Dirichlet process prior is able to limit itself to only 2 components whereas the Gaussian mixture fits the data with a fixed number of components that has to be set a priori by the user In this case the user has selected ncomponents5 which does not match the true generative distribution of this toy dataset Note that with very little observations the variational Gaussian mixture models with a Dirichlet process prior can take a conservative stand and fit only one component
On the following figure we are fitting a dataset not welldepicted by a Gaussian mixture Adjusting the weightconcentrationprior parameter of the BayesianGaussianMixture controls the number of

components used to fit this data We also present on the last two plots a random sampling generated from the two resulting mixtures

Examples

ferentweightconcentrationpriortype for different values of the parameter
weightconcentrationprior
Pros and cons of variational inference with BayesianGaussianMixture
Pros
Automatic selection whenweightconcentrationprior is small enough and
ncomponents is larger than what is found necessary by the model the Variational Bayesian
mixture model has a natural tendency to set some mixture weights values close to zero This makes
it possible to let the model choose a suitable number of effective components automatically Only an
upper bound of this number needs to be provided Note however that the “ideal” number of active
components is very application specific and is typically illdefined in a data exploration setting
Less sensitivity to the number of parameters unlike finite models which will almost always use
all components as much as they can and hence will produce wildly different solutions for
different numbers of components the variational inference with a Dirichlet process prior
weightconcentrationpriortypedirichletprocess won’t change much
with changes to the parameters leading to more stability and less tuning
Regularization due to the incorporation of prior information variational solutions have less pathological
special cases than expectationmaximization solutions
Cons
Speed the extra parametrization necessary for variational inference make inference slower although not
by much
Hyperparameters this algorithm needs an extra hyperparameter that might need experimental tuning via
crossvalidation
Bias there are many implicit biases in the inference algorithms and also in the Dirichlet process if used
and whenever there is a mismatch between these biases and the data it might be possible to fit better
models using a finite mixture
The Dirichlet Process
Here we describe variational inference algorithms on Dirichlet process mixture The Dirichlet process is a prior
probability distribution on clusterings with an infinite unbounded number of partitions Variational techniques let us
incorporate this prior structure on Gaussian mixture models at almost no penalty in inference time comparing with a
finite Gaussian mixture model
An important question is how can the Dirichlet process use an infinite unbounded number of clusters and still be
consistent While a full explanation doesn’t fit this manual one can think of its stick breaking process analogy to help
understanding it The stick breaking process is a generative story for the Dirichlet process We start with a unitlength
stick and in each step we break off a portion of the remaining stick Each time we associate the length of the piece of
the stick to the proportion of points that falls into a group of the mixture At the end to represent the infinite mixture
we associate the last remaining piece of the stick to the proportion of points that don’t fall into all the other groups The
length of each piece is a random variable with probability proportional to the concentration parameter Smaller value
of the concentration will divide the unitlength into larger pieces of the stick defining more concentrated distribution
Larger concentration values will create smaller pieces of the stick increasing the number of components with non
zero weights

Variational inference techniques for the Dirichlet process still work with a finite approximation to this infinite mixture model but instead of having to specify a priori how many components one wants to use one just specifies the concen tration parameter and an upper bound on the number of mixture components this upper bound assuming it is higher than the “true” number of components affects only algorithmic complexity not the actual number of components used

322 Manifold learning

Look for the bare necessities
The simple bare necessities
Forget about your worries and your strife
I mean the bare necessities
Old Mother Nature’s recipes
That bring the bare necessities of life
– Baloo’s song The Jungle Book

Manifold learning is an approach to nonlinear dimensionality reduction Algorithms for this task are based on the idea that the dimensionality of many data sets is only artificially high

Introduction

Highdimensional datasets can be very difficult to visualize While data in two or three dimensions can be plotted to show the inherent structure of the data equivalent highdimensional plots are much less intuitive To aid visualization of the structure of a dataset the dimension must be reduced in some way

The simplest way to accomplish this dimensionality reduction is by taking a random projection of the data Though this allows some degree of visualization of the data structure the randomness of the choice leaves much to be desired In a random projection it is likely that the more interesting structure within the data will be lost

To address this concern a number of supervised and unsupervised linear dimensionality reduction frameworks have been designed such as Principal Component Analysis PCA Independent Component Analysis Linear Discriminant Analysis and others These algorithms define specific rubrics to choose an “interesting” linear projection of the data These methods can be powerful but often miss important nonlinear structure in the data

Manifold Learning can be thought of as an attempt to generalize linear frameworks like PCA to be sensitive to non linear structure in data Though supervised variants exist the typical manifold learning problem is unsupervised it learns the highdimensional structure of the data from the data itself without the use of predetermined classifications

Examples

• See Manifold learning on handwritten digits Locally Linear Embedding Isomap for an example of dimensionality reduction on handwritten digits

• See Comparison of Manifold Learning methods for an example of dimensionality reduction on a toy “S curve” dataset

The manifold learning implementations available in scikitlearn are summarized below

Isomap

One of the earliest approaches to manifold learning is the Isomap algorithm short for Isometric Mapping Isomap can be viewed as an extension of Multidimensional Scaling MDS or Kernel PCA Isomap seeks a lowerdimensional

embedding which maintains geodesic distances between all points Isomap can be performed with the object Isomap
Complexity
The Isomap algorithm comprises three stages
1Nearest neighbor search Isomap uses sklearnneighborsBallTree for efficient neighbor search
The cost is approximately □□log□□log□ for□nearest neighbors of □points in □dimensions
2Shortestpath graph search The most efficient known algorithms for this are Dijkstra's Algorithm which is
approximately □□2□ log □ or the FloydWarshall algorithm which is □□3 The algorithm can be
selected by the user with the pathmethod keyword of Isomap If unspecified the code attempts to choose
the best algorithm for the input data
3Partial eigenvalue decomposition The embedding is encoded in the eigenvectors corresponding to the □
largest eigenvalues of the □×□isomap kernel For a dense solver the cost is approximately □□□2 This
cost can often be improved using the ARPACK solver The eigensolver can be specified by the user with the
pathmethod keyword of Isomap If unspecified the code attempts to choose the best algorithm for the
input data
The overall complexity of Isomap is □□log□□log□ □□2□ log □ □□□2
•□ number of training data points
•□ input dimension
•□ number of nearest neighbors
•□ output dimension

Locally Linear Embedding
Locally linear embedding LLE seeks a lowerdimensional projection of the data which preserves distances within local neighborhoods It can be thought of as a series of local Principal Component Analyses which are globally compared to find the best nonlinear embedding
Locally linear embedding can be performed with function locallylinearembedding or its objectoriented counterpart LocallyLinearEmbedding
Complexity
The standard LLE algorithm comprises three stages
1Nearest Neighbors Search See discussion under Isomap above
2Weight Matrix Construction □□□□3 The construction of the LLE weight matrix involves the solution of a□×□linear equation for each of the □local neighborhoods
3Partial Eigenvalue Decomposition See discussion under Isomap above
The overall complexity of standard LLE is □□log□□log□ □□□□3 □□□2
•□ number of training data points
•□ input dimension
•□ number of nearest neighbors
•□ output dimension

Modified Locally Linear Embedding
One wellknown issue with LLE is the regularization problem When the number of neighbors is greater than the number of input dimensions the matrix defining each local neighborhood is rankdeficient To address this standard

LLE applies an arbitrary regularization parameter □ which is chosen relative to the trace of the local weight matrix Though it can be shown formally that as □→0 the solution converges to the desired embedding there is no guarantee that the optimal solution will be found for □ 0 This problem manifests itself in embeddings which distort the underlying geometry of the manifold

One method to address the regularization problem is to use multiple weight vectors in each neighborhood This is the essence of modified locally linear embedding MLLE MLLE can be performed with function locallylinearembedding or its objectoriented counterpart LocallyLinearEmbedding with the key wordmethod modified It requires nneighbors ncomponents

Complexity

The MLLE algorithm comprises three stages

1Nearest Neighbors Search Same as standard LLE

2Weight Matrix Construction Approximately □□□□3□□□−□□2 The first term is exactly equivalent to that of standard LLE The second term has to do with constructing the weight matrix from multiple weights In practice the added cost of constructing the MLLE weight matrix is relatively small compared to the cost of steps 1 and 3

3Partial Eigenvalue Decomposition Same as standard LLE

The overall complexity of MLLE is □□log□□log□ □□□□3 □□□−□□2 □□□2

- □ number of training data points
- □ input dimension
- □ number of nearest neighbors
- □ output dimension

Hessian Eigenmapping
Hessian Eigenmapping also known as Hessianbased LLE HLLE is another method of solving the regularization problem of LLE It revolves around a hessianbased quadratic form at each neighborhood which is used to recover the locally linear structure Though other implementations note its poor scaling with data size sklearn implements some algorithmic improvements which make its cost comparable to that of other LLE variants for small output dimension HLLE can be performed with function locallylinearembedding or its objectoriented counterpartLocallyLinearEmbedding with the keyword method hessian It requires nneighbors ncomponents ncomponents 3 2
Complexity
The HLLE algorithm comprises three stages
1Nearest Neighbors Search Same as standard LLE
2Weight Matrix Construction Approximately □□□□3 □□□6 The first term reflects a similar cost to that of standard LLE The second term comes from a QR decomposition of the local hessian estimator
3Partial Eigenvalue Decomposition Same as standard LLE
The overall complexity of standard HLLE is □□log□□log□ □□□□3 □□□6 □□□2
•□ number of training data points
•□ input dimension
•□ number of nearest neighbors
•□ output dimension

Spectral Embedding
Spectral Embedding is an approach to calculating a nonlinear embedding Scikitlearn implements Laplacian Eigen maps which finds a low dimensional representation of the data using a spectral decomposition of the graph Laplacian The graph generated can be considered as a discrete approximation of the low dimensional manifold in the high dimen sional space Minimization of a cost function based on the graph ensures that points close to each other on the manifold are mapped close to each other in the low dimensional space preserving local distances Spectral embedding can be performed with the function spectralembedding or its objectoriented counterpart SpectralEmbedding
Complexity
The Spectral Embedding Laplacian Eigenmaps algorithm comprises three stages
1Weighted Graph Construction Transform the raw input data into graph representation using affinity adja cency matrix representation
2Graph Laplacian Construction unnormalized Graph Laplacian is constructed as □□−□for and normal ized one as □□−1
2□−□□−1
2
3Partial Eigenvalue Decomposition Eigenvalue decomposition is done on graph Laplacian
The overall complexity of spectral embedding is □□log□□log□ □□□□3 □□□2
•□ number of training data points
•□ input dimension
•□ number of nearest neighbors
•□ output dimension

Local Tangent Space Alignment
Though not technically a variant of LLE Local tangent space alignment LTSA is algorithmically similar enough to LLE that it can be put in this category Rather than focusing on preserving neighborhood distances as in LLE LTSA seeks to characterize the local geometry at each neighborhood via its tangent space and performs a global optimization to align these local tangent spaces to learn the embedding LTSA can be performed with function locallylinearembedding or its objectoriented counterpart LocallyLinearEmbedding with the key wordmethod ltsa
Complexity
The LTSA algorithm comprises three stages
1Nearest Neighbors Search Same as standard LLE
2Weight Matrix Construction Approximately □□□□3 □□2□ The first term reflects a similar cost to that of standard LLE
3Partial Eigenvalue Decomposition Same as standard LLE

The overall complexity of standard LTSA is □□log□□log□ □□□□3 □□2□ □□□2
•□ number of training data points
•□ input dimension
•□ number of nearest neighbors
•□ output dimension

Multidimensional Scaling MDS
Multidimensional scaling MDS seeks a lowdimensional representation of the data in which the distances respect well the distances in the original highdimensional space
In general is a technique used for analyzing similarity or dissimilarity data MDS attempts to model similarity or dissimilarity data as distances in a geometric spaces The data can be ratings of similarity between objects interaction frequencies of molecules or trade indices between countries
There exists two types of MDS algorithm metric and non metric In the scikitlearn the class MDS implements both In Metric MDS the input similarity matrix arises from a metric and thus respects the triangular inequality the distances between output two points are then set to be as close as possible to the similarity or dissimilarity data In the nonmetric version the algorithms will try to preserve the order of the distances and hence seek for a monotonic relationship between the distances in the embedded space and the similaritiesdissimilarities
Let□be the similarity matrix and □the coordinates of the □input points Disparities □□□are transformation of the similarities chosen in some optimal ways The objective called the stress is then defined by □□□ □□□□□□−□□□□
Metric MDS
The simplest metric MDS model called absolute MDS disparities are defined by □□□□□□ With absolute MDS the value □□□should then correspond exactly to the distance between point □and□in the embedding point

Most commonly disparities are set to □□□□□□□□
Nonmetric MDS
Non metric MDS focuses on the ordination of the data If □□□ □□□ then the embedding should enforce □□□ □□□
A simple algorithm to enforce that is to use a monotonic regression of □□□on□□□ yielding disparities □□□in the same order as □□□
A trivial solution to this problem is to set all the points on the origin In order to avoid that the disparities □□□are normalized

tdistributed Stochastic Neighbor Embedding tSNE
tSNE TSNE converts affinities of data points to probabilities The affinities in the original space are represented by Gaussian joint probabilities and the affinities in the embedded space are represented by Student’s tdistributions This allows tSNE to be particularly sensitive to local structure and has a few other advantages over existing techniques
• Revealing the structure at many scales on a single map
• Revealing data that lie in multiple different manifolds or clusters
• Reducing the tendency to crowd points together at the center
While Isomap LLE and variants are best suited to unfold a single continuous low dimensional manifold tSNE will focus on the local structure of the data and will tend to extract clustered local groups of samples as highlighted on the Scurve example This ability to group samples based on the local structure might be beneficial to visually disentangle a dataset that comprises several manifolds at once as is the case in the digits dataset
The KullbackLeibler KL divergence of the joint probabilities in the original space and the embedded space will be minimized by gradient descent Note that the KL divergence is not convex ie multiple restarts with different initializations will end up in local minima of the KL divergence Hence it is sometimes useful to try different seeds and select the embedding with the lowest KL divergence
The disadvantages to using tSNE are roughly
• tSNE is computationally expensive and can take several hours on millionsample datasets where PCA will finish in seconds or minutes
• The BarnesHut tSNE method is limited to two or three dimensional embeddings
• The algorithm is stochastic and multiple restarts with different seeds can yield different embeddings However it is perfectly legitimate to pick the embedding with the least error
• Global structure is not explicitly preserved This problem is mitigated by initializing points with PCA using initpca

Optimizing tSNE
The main purpose of tSNE is visualization of highdimensional data Hence it works best when the data will be embedded on two or three dimensions
Optimizing the KL divergence can be a little bit tricky sometimes There are five parameters that control the optimization of tSNE and therefore possibly the quality of the resulting embedding
• perplexity
• early exaggeration factor
• learning rate
• maximum number of iterations
• angle not used in the exact method
The perplexity is defined as 2where is the Shannon entropy of the conditional probability distribution The perplexity of a sided die is so that is effectively the number of nearest neighbors tSNE considers when generating the conditional probabilities Larger perplexities lead to more nearest neighbors and less sensitive to small structure Conversely a lower perplexity considers a smaller number of neighbors and thus ignores more global information in favour of the local neighborhood As dataset sizes get larger more points will be required to get a reasonable sample of the local neighborhood and hence larger perplexities may be required Similarly noisier datasets will require larger perplexity values to encompass enough local neighbors to see beyond the background noise
The maximum number of iterations is usually high enough and does not need any tuning The optimization consists of two phases the early exaggeration phase and the final optimization During early exaggeration the joint probabilities in the original space will be artificially increased by multiplication with a given factor Larger factors result in larger gaps between natural clusters in the data If the factor is too high the KL divergence could increase during this phase Usually it does not have to be tuned A critical parameter is the learning rate If it is too low gradient descent will get stuck in a bad local minimum If it is too high the KL divergence will increase during optimization More tips can be found in Laurens van der Maaten’s FAQ see references The last parameter angle is a tradeoff between performance and accuracy Larger angles imply that we can approximate larger regions by a single point leading to better speed but less accurate results
“How to Use tSNE Effectively” provides a good discussion of the effects of the various parameters as well as interactive plots to explore the effects of different parameters
BarnesHut tSNE
The BarnesHut tSNE that has been implemented here is usually much slower than other manifold learning algorithms The optimization is quite difficult and the computation of the gradient is where is the number of output dimensions and is the number of samples The BarnesHut method improves on the exact method where tSNE complexity is 2 but has several other notable differences
• The BarnesHut implementation only works when the target dimensionality is 3 or less The 2D case is typical when building visualizations
• BarnesHut only works with dense input data Sparse data matrices can only be embedded with the exact method or can be approximated by a dense low rank projection for instance using sklearndecomposition TruncatedSVD
• BarnesHut is an approximation of the exact method The approximation is parameterized with the angle parameter therefore the angle parameter is unused when method”exact”
• BarnesHut is significantly more scalable BarnesHut can be used to embed hundred of thousands of data points while the exact method can handle thousands of samples before becoming computationally intractable

For visualization purpose which is the main use case of tSNE using the BarnesHut method is strongly recommended The exact tSNE method is useful for checking the theoretically properties of the embedding possibly in higher dimensional space but limit to small datasets due to computational constraints

Also note that the digits labels roughly match the natural grouping found by tSNE while the linear 2D projection of the PCA model yields a representation where label regions largely overlap This is a strong clue that this data can be well separated by non linear methods that focus on the local structure eg an SVM with a Gaussian RBF kernel However failing to visualize well separated homogeneously labeled groups with tSNE in 2D does not necessarily imply that the data cannot be correctly classified by a supervised model It might be the case that 2 dimensions are not low enough to accurately represents the internal structure of the data

Tips on practical use

• Make sure the same scale is used over all features Because manifold learning methods are based on a nearest neighbor search the algorithm may perform poorly otherwise See StandardScaler for convenient ways of scaling heterogeneous data
• The reconstruction error computed by each routine can be used to choose the optimal output dimension For a □dimensional manifold embedded in a □dimensional parameter space the reconstruction error will decrease asncomponents is increased until ncomponents d
• Note that noisy data can “shortcircuit” the manifold in essence acting as a bridge between parts of the manifold that would otherwise be wellseparated Manifold learning on noisy andor incomplete data is an active area of research
• Certain input configurations can lead to singular weight matrices for example when more than two points in the dataset are identical or when the data is split into disjointed groups In this case solverarpack will fail to find the null space The easiest way to address this is to use solverdense which will work on a singular matrix though it may be very slow depending on the number of input points Alternatively one can attempt to understand the source of the singularity if it is due to disjoint sets increasing nneighbors may help If it is due to identical points in the dataset removing these points may help

Totally Random Trees Embedding can also be useful to derive nonlinear representations of feature space also it does not perform dimensionality reduction

323 Clustering

Clustering of unlabeled data can be performed with the module sklearncluster

Each clustering algorithm comes in two variants a class that implements the fit method to learn the clusters on train data and a function that given train data returns an array of integer labels corresponding to the different clusters For the class the labels over the training data can be found in the labels attribute

Input data
One important thing to note is that the algorithms implemented in this module can take different kinds of matrix as input All the methods accept standard data matrices of shape nsamples nfeatures These can be ob tained from the classes in the sklearnfeatureextraction module For AffinityPropagation SpectralClustering andDBSCAN one can also input similarity matrices of shape nsamples nsamples These can be obtained from the functions in the sklearnmetricspairwise module
Overview of clustering methods

points from although they live in the same space
The Kmeans algorithm aims to choose centroids that minimise the inertia orwithincluster sumofsquares crite
rion
Σ
0min
∈−2
Inertia can be recognized as a measure of how internally coherent clusters are It suffers from various drawbacks
• Inertia makes the assumption that clusters are convex and isotropic which is not always the case It responds
poorly to elongated clusters or manifolds with irregular shapes
• Inertia is not a normalized metric we just know that lower values are better and zero is optimal But in very
highdimensional spaces Euclidean distances tend to become inflated this is an instance of the socalled “curse
of dimensionality” Running a dimensionality reduction algorithm such as Principal component analysis PCA
prior to kmeans clustering can alleviate this problem and speed up the computations
K
means is often referred to as Lloyd’s algorithm In basic terms the algorithm has three steps The first step chooses
the initial centroids with the most basic method being to choose samples from the dataset After initialization

Kmeans consists of looping between the two other steps The first step assigns each sample to its nearest centroid The second step creates new centroids by taking the mean value of all of the samples assigned to each previous centroid The difference between the old and the new centroids are computed and the algorithm repeats these last two steps until this value is less than a threshold In other words it repeats until the centroids do not move significantly Kmeans is equivalent to the expectationmaximization algorithm with a
small allequal diagonal covariance matrix
The algorithm can also be understood through the concept of V oronoi diagrams First the V oronoi diagram of the points is calculated using the current centroids Each segment in the V oronoi diagram becomes a separate cluster Secondly the centroids are updated to the mean of each segment The algorithm then repeats this until a stopping criterion is fulfilled Usually the algorithm stops when the relative decrease in the objective function between iterations is less than the given tolerance value This is not the case in this implementation iteration stops when centroids move less than the tolerance
Given enough time Kmeans will always converge however this may be to a local minimum This is highly depen dent on the initialization of the centroids As a result the computation is often done several times with different initializations of the centroids One method to help address this issue is the kmeans initialization scheme which has been implemented in scikitlearn use the initkmeans parameter This initializes the centroids to
be generally distant from each other leading to provably better results than random initialization as shown in the reference
The algorithm supports sample weights which can be given by a parameter sampleweight This allows to assign more weight to some samples when computing cluster centers and values of inertia For example assigning a weight of 2 to a sample is equivalent to adding a duplicate of that sample to the dataset
A parameter can be given to allow Kmeans to be run in parallel called njobs Giving this parameter a positive value uses that many processors default 1 A value of 1 uses all available processors with 2 using one less and so on Parallelization generally speeds up computation at the cost of memory in this case multiple copies of centroids need to be stored one for each job
Warning The parallel version of KMeans is broken on OS X when numpy uses theAccelerate Framework
This is expected behavior Accelerate can be called after a fork but you need to execv the subprocess with the Python binary which multiprocessing does not do under posix
Kmeans can be used for vector quantization This is achieved using the transform method of a trained model of KMeans
Examples
•Demonstration of kmeans assumptions Demonstrating when kmeans performs intuitively and when it does not
•A demo of KMeans clustering on the handwritten digits data Clustering handwritten digits

Mini Batch KMeans
TheMiniBatchKMeans is a variant of the KMeans algorithm which uses minibatches to reduce the computation time while still attempting to optimise the same objective function Minibatches are subsets of the input data ran domly sampled in each training iteration These minibatches drastically reduce the amount of computation required to converge to a local solution In contrast to other algorithms that reduce the convergence time of kmeans minibatch kmeans produces results that are generally only slightly worse than the standard algorithm
The algorithm iterates between two major steps similar to vanilla kmeans In the first step samples are drawn randomly from the dataset to form a minibatch These are then assigned to the nearest centroid In the second step the centroids are updated In contrast to kmeans this is done on a persample basis For each sample in the minibatch the assigned centroid is updated by taking the streaming average of the sample and all previous samples assigned to that centroid This has the effect of decreasing the rate of change for a centroid over time These steps are performed until convergence or a predetermined number of iterations is reached
MiniBatchKMeans converges faster than KMeans but the quality of the results is reduced In practice this differ ence in quality can be quite small as shown in the example and cited reference
Examples

Affinity Propagation
AffinityPropagation creates clusters by sending messages between pairs of samples until convergence A dataset is then described using a small number of exemplars which are identified as those most representative of other samples The messages sent between pairs represent the suitability for one sample to be the exemplar of the other which is updated in response to the values from other pairs This updating happens iteratively until convergence at which point the final exemplars are chosen and hence the final clustering is given
Affinity Propagation can be interesting as it chooses the number of clusters based on the data provided For this pur pose the two important parameters are the preference which controls how many exemplars are used and the damping factor which damps the responsibility and availability messages to avoid numerical oscillations when updating these messages
The main drawback of Affinity Propagation is its complexity The algorithm has a time complexity of the order □□2□ where □is the number of samples and □is the number of iterations until convergence Further the memory complexity is of the order □□2if a dense similarity matrix is used but reducible if a sparse similarity matrix is used This makes Affinity Propagation most appropriate for small to medium sized datasets
Examples
•Demo of affinity propagation clustering algorithm Affinity Propagation on a synthetic 2D datasets with 3 classes
•Visualizing the stock market structure Affinity Propagation on Financial time series to find groups of compa nies
Algorithm description The messages sent between points belong to one of two categories The first is the responsi bility □□ □ which is the accumulated evidence that sample □should be the exemplar for sample □ The second is the availability □□ □which is the accumulated evidence that sample □should choose sample □to be its exemplar and considers the values for all other samples that □should be an exemplar In this way exemplars are chosen by samples if they are 1 similar enough to many samples and 2 chosen by many samples to be representative of themselves

More formally the responsibility of a sample □to be the exemplar of sample □is given by
□□ □←□□ □−□□□□□ □′ □□ □′∀□′□
Where □□ □is the similarity between samples □and□ The availability of sample □to be the exemplar of sample □is given by
□□ □←□□□0 □□ □ ∑
□′□□ □′∈□□□□′ □
To begin with all values for □and□are set to zero and the calculation of each iterates until convergence As discussed above in order to avoid numerical oscillations when updating the messages the damping factor □is introduced to iteration process

□□□□
□
Where □□□is the neighborhood of samples within a given distance around □□and□is the mean shift vector that is computed for each centroid that points towards a region of the maximum increase in the density of points This is computed using the following equation effectively updating a centroid to be the mean of the samples within its neighborhood
□□□ ∑
□□∈□□□□□□−□□□□∑
□□∈□□□□□□−□□
The algorithm automatically sets the number of clusters instead of relying on a parameter bandwidth which dictates the size of the region to search through This parameter can be set manually but can be estimated using the provided estimatebandwidth function which is called if the bandwidth is not set
The algorithm is not highly scalable as it requires multiple nearest neighbor searches during the execution of the algorithm The algorithm is guaranteed to converge however the algorithm will stop iterating when the change in centroids is small
Labelling a new sample is performed by finding the nearest centroid for a given sample
Examples
•A demo of the meanshift clustering algorithm Mean Shift clustering on a synthetic 2D datasets with 3 classes

Spectral clustering
SpectralClustering does a lowdimension embedding of the affinity matrix between samples followed by a KMeans in the low dimensional space It is especially efficient if the affinity matrix is sparse and the pyamg module is installed SpectralClustering requires the number of clusters to be specified It works well for a small number of clusters but is not advised when using many clusters
For two clusters it solves a convex relaxation of the normalised cuts problem on the similarity graph cutting the graph in two so that the weight of the edges cut is small compared to the weights of the edges inside each cluster This criteria is especially interesting when working on images graph vertices are pixels and edges of the similarity graph are a function of the gradient of the image
Warning Transforming distance to wellbehaved similarities
Note that if the values of your similarity matrix are not well distributed eg with negative values or with a distance

matrix rather than a similarity the spectral problem will be singular and the problem not solvable In which case it is advised to apply a transformation to the entries of the matrix For instance in the case of a signed distance matrix is common to apply a heat kernel
similarity npexpbeta distance distancestd
See the examples for such an application
Examples
•Spectral clustering for image segmentation Segmenting objects from a noisy background using spectral clustering
•Segmenting the picture of greek coins in regions Spectral clustering to split the image of coins in regions
Different label assignment strategies
Different label assignment strategies can be used corresponding to the assignlabels parameter of SpectralClustering Thekmeans strategy can match finer details of the data but it can be more unsta ble In particular unless you control the randomstate it may not be reproducible from runtorun as it depends on a random initialization On the other hand the discretize strategy is 100 reproducible but it tends to create parcels of fairly even and geometrical shape
assignlabelskmeans assignlabelsdiscretize
Spectral Clustering Graphs
Spectral Clustering can also be used to cluster graphs by their spectral embeddings In this case the affinity matrix is the adjacency matrix of the graph and SpectralClustering is initialized with affinityprecomputed

```
 from sklearncluster import SpectralClustering
sc  SpectralClustering3 affinityprecomputed ninit100
 assignlabelsdiscretize
scfitpredictadjacencymatrix
```

Hierarchical clustering

Hierarchical clustering is a general family of clustering algorithms that build nested clusters by merging or splitting them successively This hierarchy of clusters is represented as a tree or dendrogram The root of the tree is the unique cluster that gathers all the samples the leaves being the clusters with only one sample See the Wikipedia page for more details

TheAgglomerativeClustering object performs a hierarchical clustering using a bottom up approach each observation starts in its own cluster and clusters are successively merged together The linkage criteria determines the metric used for the merge strategy

•Ward minimizes the sum of squared differences within all clusters It is a varianceminimizing approach and in this sense is similar to the kmeans objective function but tackled with an agglomerative hierarchical approach
•Maximum orcomplete linkage minimizes the maximum distance between observations of pairs of clusters
•Average linkage minimizes the average of the distances between all observations of pairs of clusters
•Single linkage minimizes the distance between the closest observations of pairs of clusters

AgglomerativeClustering can also scale to large number of samples when it is used jointly with a connectivity matrix but is computationally expensive when no connectivity constraints are added between samples it considers at each step all the possible merges

FeatureAgglomeration

TheFeatureAgglomeration uses agglomerative clustering to group together features that look very similar thus decreasing the number of features It is a dimensionality reduction tool see Unsupervised dimensionality reduction

Different linkage type Ward complete average and single linkage

AgglomerativeClustering supports Ward single average and complete linkage strategies

Ag
glomerative cluster has a “rich get richer” behavior that leads to uneven cluster sizes In this regard single linkage is the worst strategy and Ward gives the most regular sizes However the affinity or distance used in clustering cannot be varied with Ward thus for non Euclidean metrics average linkage is a good alternative Single linkage while not robust to noisy data can be computed very efficiently and can therefore be useful to provide hierarchical clustering of larger datasets Single linkage can also perform well on nonglobular data

Examples

•Various Agglomerative Clustering on a 2D embedding of digits exploration of the different linkage strategies in a real dataset

Adding connectivity constraints
An interesting aspect of AgglomerativeClustering is that connectivity constraints can be added to this al
gorithm only adjacent clusters can be merged together through a connectivity matrix that defines for each sample
the neighboring samples following a given structure of the data For instance in the swissroll example below the
connectivity constraints forbid the merging of points that are not adjacent on the swiss roll and thus avoid forming
clusters that extend across overlapping folds of the roll
These constraint are useful to impose a certain local structure but they also make the algorithm faster especially when
the number of the samples is high
The connectivity constraints are imposed via an connectivity matrix a scipy sparse matrix that has elements only
at the intersection of a row and a column with indices of the dataset that should be connected This matrix can
be constructed from apriori information for instance you may wish to cluster web pages by only merging pages
with a link pointing from one to another It can also be learned from the data for instance using sklearn
neighborskneighborsgraph to restrict merging to nearest neighbors as in this example or usingsklearn
featureextractionimagegridtograph to enable only merging of neighboring pixels on an image
as in the coin example
Examples
•A demo of structured Ward hierarchical clustering on an image of coins Ward clustering to split the image
of coins in regions
•Hierarchical clustering structured vs unstructured ward Example of Ward algorithm on a swissroll com
parison of structured approaches versus unstructured approaches
•Feature agglomeration vs univariate selection Example of dimensionality reduction with feature agglomer
ation based on Ward hierarchical clustering
•Agglomerative clustering with and without structure
Warning Connectivity constraints with single average and complete linkage
Connectivity constraints and single complete or average linkage can enhance the ‘rich getting richer’ aspect of
agglomerative clustering particularly so if they are built with sklearnneighborskneighborsgraph
In the limit of a small number of clusters they tend to give a few macroscopically occupied clusters and almost
empty ones see the discussion in Agglomerative clustering with and without structure Single linkage is the
most brittle linkage option with regard to this issue

Varying the metric
Single average and complete linkage can be used with a variety of distances or affinities in particular Euclidean distance l2 Manhattan distance or Cityblock or l1 cosine distance or any precomputed affinity matrix
•l1distance is often good for sparse features or sparse noise ie many of the features are zero as in text mining using occurrences of rare words
•cosine distance is interesting because it is invariant to global scalings of the signal
The guidelines for choosing a metric is to use one that maximizes the dis
tance between samples in different classes and minimizes that within each class
Examples
•Agglomerative clustering with different metrics
DBSCAN
TheDBSCAN algorithm views clusters as areas of high density separated by areas of low density Due to this rather generic view clusters found by DBSCAN can be any shape as opposed to kmeans which assumes that clusters are convex shaped The central component to the DBSCAN is the concept of core samples which are samples that are in areas of high density A cluster is therefore a set of core samples each close to each other measured by some distance measure and a set of noncore samples that are close to a core sample but are not themselves core samples There are two parameters to the algorithm minsamples andeps which define formally what we mean when we say dense Higherminsamples or lowereps indicate higher density necessary to form a cluster
More formally we define a core sample as being a sample in the dataset such that there exist minsamples other samples within a distance of eps which are defined as neighbors of the core sample This tells us that the core sample is in a dense area of the vector space A cluster is a set of core samples that can be built by recursively taking a core sample finding all of its neighbors that are core samples finding all of their neighbors that are core samples and so on A cluster also has a set of noncore samples which are samples that are neighbors of a core sample in the cluster but are not themselves core samples Intuitively these samples are on the fringes of a cluster

Any core sample is part of a cluster by definition Any sample that is not a core sample and is at least eps in distance from any core sample is considered an outlier by the algorithm
While the parameter minsamples primarily controls how tolerant the algorithm is towards noise on noisy and large data sets it may be desiable to increase this parameter the parameter eps iscrucial to choose appropriately for the data set and distance function and usually cannot be left at the default value It controls the local neighborhood of the points When chosen too small most data will not be clustered at all and labeled as 1for “noise” When chosen too large it causes close clusters to be merged into one cluster and eventually the entire data set to be returned as a single cluster Some heuristics for choosing this parameter have been discussed in literature for example based on a knee in the nearest neighbor distances plot as discussed in the references below
In the figure below the color indicates cluster membership with large circles indicating core samples found by the algorithm Smaller circles are noncore samples that are still part of a cluster Moreover the outliers are indicated by black points below
Examples
•Demo of DBSCAN clustering algorithm
Implementation
The DBSCAN algorithm is deterministic always generating the same clusters when given the same data in the same order However the results can differ when data is provided in a different order First even though the core samples will always be assigned to the same clusters the labels of those clusters will depend on the order in which those samples are encountered in the data Second and more importantly the clusters to which noncore samples are assigned can differ depending on the data order This would happen when a noncore sample has a distance lower thaneps to two core samples in different clusters By the triangular inequality those two core samples must be more distant than eps from each other or they would be in the same cluster The noncore sample is assigned to whichever cluster is generated first in a pass through the data and so the results will depend on the data ordering
The current implementation uses ball trees and kdtrees to determine the neighborhood of points which avoids calculating the full distance matrix as was done in scikitlearn versions before 014 The possibility to use custom metrics is retained for details see NearestNeighbors
Memory consumption for large sample sizes

This implementation is by default not memory efficient because it constructs a full pairwise similarity matrix in the case where kdtrees or balltrees cannot be used eg with sparse matrices This matrix will consume n2 floats A couple of mechanisms for getting around this are

• Use OPTICS clustering in conjunction with the extractdbscan method OPTICS clustering also calculates the full pairwise matrix but only keeps one row in memory at a time memory complexity n
• A sparse radius neighborhood graph where missing entries are presumed to be out of eps can be precomputed in a memoryefficient way and dbscan can be run over this with metricprecomputed See sklearnneighborsNearestNeighborsradiusneighborsgraph
• The dataset can be compressed either by removing exact duplicates if these occur in your data or by using BIRCH Then you only have a relatively small number of representatives for a large number of points You can then provide a sampleweight when fitting DBSCAN

OPTICS

TheOPTICS algorithm shares many similarities with the DBSCAN algorithm and can be considered a generalization of DBSCAN that relaxes the eps requirement from a single value to a value range The key difference between DBSCAN and OPTICS is that the OPTICS algorithm builds a reachability graph which assigns each sample both areachability distance and a spot within the cluster ordering attribute these two attributes are assigned when the model is fitted and are used to determine cluster membership If OPTICS is run with the default value of inf set formaxeps then DBSCAN style cluster extraction can be performed repeatedly in linear time for any given eps value using the clusteropticsdbscan method Setting maxeps to a lower value will result in shorter run times and can be thought of as the maximum neighborhood radius from each point to find other potential reachable points

Thereachability distances generated by OPTICS allow for variable density extraction of clusters within a single data set As shown in the above plot combining reachability distances and data set ordering produces a reachability plot where point density is represented on the Yaxis and points are ordered such that nearby points are adjacent ‘Cutting’ the reachability plot at a single value produces DBSCAN like results all points above the ‘cut’ are classified as noise and each time that there is a break when reading from left to right signifies a new cluster The default cluster extraction with OPTICS looks at the steep slopes within the graph to find clusters and the user can define what counts as a steep slope using the parameter xi There are also other possibilities for analysis on the graph itself such as generating hierarchical representations of the data through reachabilityplot dendrograms and the hierarchy of clusters detected by the algorithm can be accessed through the clusterhierarchy parameter The plot above has been colorcoded so that cluster colors in planar space match the linear segment clusters of the reachability plot Note that the blue and red clusters are adjacent in the reachability plot and can be hierarchically represented as children of a larger parent cluster

Examples

•Demo of OPTICS clustering algorithm

Comparison with DBSCAN

The results from OPTICS clusteropticsdbscan method and DBSCAN are very similar but not always identical specifically labeling of periphery and noise points This is in part because the first samples of each dense area processed by OPTICS have a large reachability value while being close to other points in their area and will thus sometimes be marked as noise rather than periphery This affects adjacent points when they are considered as candidates for being marked as either periphery or noise

Note that for any single value of eps DBSCAN will tend to have a shorter run time than OPTICS however for repeated runs at varying eps values a single run of OPTICS may require less cumulative runtime than DBSCAN It is also important to note that OPTICS’ output is close to DBSCAN’s only if eps andmaxeps are close

Computational Complexity
Spatial indexing trees are used to avoid calculating the full distance matrix and allow for efficient memory usage on large sets of samples Different distance metrics can be supplied via the metric keyword
For large datasets similar but not identical results can be obtained via HDBSCAN The HDBSCAN implementation is multithreaded and has better algorithmic runtime complexity than OPTICS at the cost of worse memory scaling For extremely large datasets that exhaust system memory using HDBSCAN OPTICS will maintain nas opposed to n2 memory scaling however tuning of the maxeps parameter will likely need to be used to give a solution in a reasonable amount of wall time

Birch
TheBirch builds a tree called the Characteristic Feature Tree CFT for the given data The data is essentially lossy compressed to a set of Characteristic Feature nodes CF Nodes The CF Nodes have a number of subclusters called Characteristic Feature subclusters CF Subclusters and these CF Subclusters located in the nonterminal CF Nodes can have CF Nodes as children
The CF Subclusters hold the necessary information for clustering which prevents the need to hold the entire input data in memory This information includes
• Number of samples in a subcluster
• Linear Sum A ndimensional vector holding the sum of all samples
• Squared Sum Sum of the squared L2 norm of all samples
• Centroids To avoid recalculation linear sum nsamples
• Squared norm of the centroids
The Birch algorithm has two parameters the threshold and the branching factor The branching factor limits the number of subclusters in a node and the threshold limits the distance between the entering sample and the existing subclusters
This algorithm can be viewed as an instance or data reduction method since it reduces the input data to a set of subclusters which are obtained directly from the leaves of the CFT This reduced data can be further processed by feeding it into a global clusterer This global clusterer can be set by nclusters Ifnclusters is set to None the subclusters from the leaves are directly read off otherwise a global clustering step labels these subclusters into global clusters labels and the samples are mapped to the global label of the nearest subcluster
Algorithm description
• A new sample is inserted into the root of the CF Tree which is a CF Node It is then merged with the subcluster of the root that has the smallest radius after merging constrained by the threshold and branching factor conditions If the subcluster has any child node then this is done repeatedly till it reaches a leaf After finding the nearest subcluster in the leaf the properties of this subcluster and the parent subclusters are recursively updated
• If the radius of the subcluster obtained by merging the new sample and the nearest subcluster is greater than the square of the threshold and if the number of subclusters is greater than the branching factor then a space is temporarily allocated to this new sample The two farthest subclusters are taken and the subclusters are divided into two groups on the basis of the distance between these subclusters

• If this split node has a parent subcluster and there is room for a new subcluster then the parent is split into two If there is no room then this node is again split into two and the process is continued recursively till it reaches the root

Birch or MiniBatchKMeans

• Birch does not scale very well to high dimensional data As a rule of thumb if nfeatures is greater than twenty it is generally better to use MiniBatchKMeans
• If the number of instances of data needs to be reduced or if one wants a large number of subclusters either as a preprocessing step or otherwise Birch is more useful than MiniBatchKMeans

How to use partialfit

To avoid the computation of global clustering for every call of partialfit the user is advised
1 To setnclustersNone initially
2 Train all data by multiple calls to partialfit
3 Setnclusters to a required value using brcsetparamsnclustersnclusters
4 Callpartialfit finally with no arguments ie brcpartialfit which performs the global clus tering

Clustering performance evaluation

Evaluating the performance of a clustering algorithm is not as trivial as counting the number of errors or the precision and recall of a supervised classification algorithm In particular any evaluation metric should not take the absolute values of the cluster labels into account but rather if this clustering define separations of the data similar to some ground truth set of classes or satisfying some assumption such that members belong to the same class are more similar that members of different classes according to some similarity metric

Adjusted Rand index
Given the knowledge of the ground truth class assignments labelstrue and our clustering algorithm assignments of the same samples labelspred the adjusted Rand index is a function that measures the similarity of the two assignments ignoring permutations and with chance normalization

```
 from sklearn import metrics
labelstrue  0 0 0 1 1 1
labelspred  0 0 1 1 2 2
metricsadjustedrandscorelabelstrue labelspred
024
```

One can permute 0 and 1 in the predicted labels rename 2 to 3 and get the same score

```
labelspred  1 1 0 0 3 3
metricsadjustedrandscorelabelstrue labelspred
024
```

Furthermore adjustedrandscore issymmetric swapping the argument does not change the score It can thus be used as a consensus measure

```
metricsadjustedrandscorelabelspred labelstrue
024
```

Perfect labeling is scored 10

```
labelspred  labelstrue
metricsadjustedrandscorelabelstrue labelspred
10
```

Bad eg independent labelings have negative or close to 00 scores

```
labelstrue  0 1 2 0 3 4 5 1
labelspred  1 1 0 0 2 2 2 2
metricsadjustedrandscorelabelstrue labelspred
012
```

Advantages

•Random uniform label assignments have a ARI score close to 00 for any value of nclusters and nsamples which is not the case for raw Rand index or the Vmeasure for instance

•Bounded range 1 1 negative values are bad independent labelings similar clusterings have a positive ARI 10 is the perfect match score

•No assumption is made on the cluster structure can be used to compare clustering algorithms such as k means which assumes isotropic blob shapes with results of spectral clustering algorithms which can find cluster with “folded” shapes

Drawbacks

• Contrary to inertia ARI requires knowledge of the ground truth classes while is almost never available in practice or requires manual assignment by human annotators as in the supervised learning setting

However ARI can also be useful in a purely unsupervised setting as a building block for a Consensus Index that can be used for clustering model selection TODO

Examples

•Adjustment for chance in clustering performance evaluation Analysis of the impact of the dataset size on the value of clustering measures for random assignments

Mathematical formulation

If C is a ground truth class assignment and K the clustering let us define □and□as

•□ the number of pairs of elements that are in the same set in C and in the same set in K

•□ the number of pairs of elements that are in different sets in C and in different sets in K

The raw unadjusted Rand index is then given by

RI□□

□□□□□□□□□□

2

Where □□□□□□□□□□

2 is the total number of possible pairs in the dataset without ordering

However the RI score does not guarantee that random label assignments will get a value close to zero esp if the number of clusters is in the same order of magnitude as the number of samples

To counter this effect we can discount the expected RI □RIof random labelings by defining the adjusted Rand index as follows

ARIRI−□RI

max RI−□RI

Mutual Information based scores

Given the knowledge of the ground truth class assignments labelstrue and our clustering algorithm assignments of the same samples labelspred the Mutual Information is a function that measures the agreement of the two assignments ignoring permutations Two different normalized versions of this measure are available Normalized Mutual Information NMI andAdjusted Mutual Information AMI NMI is often used in the literature while AMI was proposed more recently and is normalized against chance

```
 from sklearn import metrics
labelstrue  0 0 0 1 1 1
labelspred  0 0 1 1 2 2
metricsadjustedmutualinfoscorelabelstrue labelspred
```

022504

One can permute 0 and 1 in the predicted labels rename 2 to 3 and get the same score

labelspred 1 1 0 0 3 3
metricsadjustedmutualinfoscorelabelstrue labelspred
022504
Allmutualinfoscore adjustedmutualinfoscore andnormalizedmutualinfoscore
are symmetric swapping the argument does not change the score Thus they can be used as a consensus measure
metricsadjustedmutualinfoscorelabelspred labelstrue
022504
Perfect labeling is scored 10
labelspred labelstrue
metricsadjustedmutualinfoscorelabelstrue labelspred
10
metricsnormalizedmutualinfoscorelabelstrue labelspred
10
This is not true for mutualinfoscore which is therefore harder to judge
metricsmutualinfoscorelabelstrue labelspred
069
Bad eg independent labelings have nonpositive scores
labelstrue 0 1 2 0 3 4 5 1
labelspred 1 1 0 0 2 2 2 2
metricsadjustedmutualinfoscorelabelstrue labelspred
010526
Advantages
•Random uniform label assignments have a AMI score close to 00 for any value of nclusters and
nsamples which is not the case for raw Mutual Information or the Vmeasure for instance
•Upper bound of 1 Values close to zero indicate two label assignments that are largely independent while
values close to one indicate significant agreement Further an AMI of exactly 1 indicates that the two label
assignments are equal with or without permutation
Drawbacks
• Contrary to inertia MIbased measures require the knowledge of the ground truth classes while almost
never available in practice or requires manual assignment by human annotators as in the supervised learning
setting
However MIbased measures can also be useful in purely unsupervised setting as a building block for a Consen
sus Index that can be used for clustering model selection
• NMI and MI are not adjusted against chance
Examples

•Adjustment for chance in clustering performance evaluation Analysis of the impact of the dataset size on the value of clustering measures for random assignments This example also includes the Adjusted Rand Index
Mathematical formulation
Assume two label assignments of the same N objects □and□ Their entropy is the amount of uncertainty for a partition set defined by
□□ −□∑
□1□□ log □□
where □□ □□□is the probability that an object picked at random from □falls into class □□ Likewise for □
□□ −□∑
□1□′□ log □′□
With □′□ □□□ The mutual information MI between □and□is calculated by
MI□ □ □∑
□1□∑
□1□□ □ log□□ □
□□□′□
where □□ □ □□∩□□□is the probability that an object picked at random falls into both classes □□and□□
It also can be expressed in set cardinality formulation
MI□ □ □∑
□1□∑
□1□□∩□□
□log□□□∩□□
□□□□
The normalized mutual information is defined as
NMI□ □ MI□ □
mean □□ □□
This value of the mutual information and also the normalized variant is not adjusted for chance and will tend to increase as the number of different labels clusters increases regardless of the actual amount of “mutual information” between the label assignments
The expected value for the mutual information can be calculated using the following equation VEB2009 In this equation □□□□the number of elements in □□ and □□□□the number of elements in □□
□MI□ □ □∑
□1□∑
□1min□□□□∑
□□□□□□□−□□□□
□log□□□□
□□□□□□□□□−□□□−□□
□□□□□□−□□□□□−□□□□−□□−□□□□□
Using the expected value the adjusted mutual information can then be calculated using a similar form to that of the adjusted Rand index
AMI MI−□MI
mean □□ □□−□MI
For normalized mutual information and adjusted mutual information the normalizing value is typically some gener alized mean of the entropies of each clustering Various generalized means exist and no firm rules exist for preferring one over the others The decision is largely a fieldbyfield basis for instance in community detection the arithmetic mean is most common Each normalizing method provides “qualitatively similar behaviours” YAT2016 In our implementation this is controlled by the averagemethod parameter
Vinh et al 2010 named variants of NMI and AMI by their averaging method VEB2010 Their ‘sqrt’ and ‘sum’ averages are the geometric and arithmetic means we use these more broadly common names

Homogeneity completeness and Vmeasure
Given the knowledge of the ground truth class assignments of the samples it is possible to define some intuitive metric
using conditional entropy analysis
In particular Rosenberg and Hirschberg 2007 define the following two desirable objectives for any cluster assign
ment
•homogeneity each cluster contains only members of a single class
•completeness all members of a given class are assigned to the same cluster
We can turn those concept as scores homogeneityscore andcompletenessscore Both are bounded
below by 00 and above by 10 higher is better
```
 from sklearn import metrics
labelstrue  0 0 0 1 1 1
labelspred  0 0 1 1 2 2
metricshomogeneityscorelabelstrue labelspred
066
metricscompletenessscorelabelstrue labelspred
042
```
Their harmonic mean called Vmeasure is computed by vmeasurescore
```
metricsvmeasurescorelabelstrue labelspred
051
```
This function’s formula is as follows
```
 math v  frac1  beta times texthomogeneity times textcompleteness
‘→beta times texthomogeneity  textcompleteness
```
beta defaults to a value of 10 but for using a value less than 1 for beta
```
metricsvmeasurescorelabelstrue labelspred beta06
054
```
more weight will be attributed to homogeneity and using a value greater than 1
```
metricsvmeasurescorelabelstrue labelspred beta18
048
```
more weight will be attributed to completeness

The Vmeasure is actually equivalent to the mutual information NMI discussed above with the aggregation function being the arithmetic mean B2011
Homogeneity completeness and Vmeasure can be computed at once using homogeneitycompletenessvmeasure as follows
metricshomogeneitycompletenessvmeasurelabelstrue labelspred

066 042 051
The following clustering assignment is slightly better since it is homogeneous but not complete
labelspred 0 0 0 1 2 2
metricshomogeneitycompletenessvmeasurelabelstrue labelspred

10 068 081
Notevmeasurescore issymmetric it can be used to evaluate the agreement of two independent assignments on the same dataset
This is not the case for completenessscore andhomogeneityscore both are bound by the relationship homogeneityscorea b completenessscoreb a
Advantages
•Bounded scores 00 is as bad as it can be 10 is a perfect score
• Intuitive interpretation clustering with bad Vmeasure can be qualitatively analyzed in terms of homogeneity and completeness to better feel what ‘kind’ of mistakes is done by the assignment
•No assumption is made on the cluster structure can be used to compare clustering algorithms such as k means which assumes isotropic blob shapes with results of spectral clustering algorithms which can find cluster with “folded” shapes
Drawbacks
• The previously introduced metrics are not normalized with regards to random labeling this means that depending on the number of samples clusters and ground truth classes a completely random labeling will not always yield the same values for homogeneity completeness and hence vmeasure In particular random labeling won’t yield zero scores especially when the number of clusters is large
This problem can safely be ignored when the number of samples is more than a thousand and the number of clusters is less than 10 For smaller sample sizes or larger number of clusters it is safer to use an adjusted index such as the Adjusted Rand Index ARI
• These metrics require the knowledge of the ground truth classes while almost never available in practice or requires manual assignment by human annotators as in the supervised learning setting
Examples
•Adjustment for chance in clustering performance evaluation Analysis of the impact of the dataset size on the value of clustering measures for random assignments

Mathematical formulation
Homogeneity and completeness scores are formally given by
h 1−□□□
□□
□ 1−□□□
□□
where □□□is the conditional entropy of the classes given the cluster assignments and is given by
□□□ −□∑
□1□∑
□1□□□

labelspred labelstrue
metricsfowlkesmallowsscorelabelstrue labelspred
10
Bad eg independent labelings have zero scores
labelstrue 0 1 2 0 3 4 5 1
labelspred 1 1 0 0 2 2 2 2
metricsfowlkesmallowsscorelabelstrue labelspred
00
Advantages
•Random uniform label assignments have a FMI score close to 00 for any value of nclusters and nsamples which is not the case for raw Mutual Information or the Vmeasure for instance
•Upperbounded at 1 Values close to zero indicate two label assignments that are largely independent while values close to one indicate significant agreement Further values of exactly 0 indicate purely independent label assignments and a FMI of exactly 1 indicates that the two label assignments are equal with or without permutation
•No assumption is made on the cluster structure can be used to compare clustering algorithms such as k means which assumes isotropic blob shapes with results of spectral clustering algorithms which can find cluster with “folded” shapes
Drawbacks
• Contrary to inertia FMIbased measures require the knowledge of the ground truth classes while almost never available in practice or requires manual assignment by human annotators as in the supervised learning setting

Silhouette Coefficient
If the ground truth labels are not known evaluation must be performed using the model itself The Silhouette Coeffi cient sklearnmetricssilhouettescore is an example of such an evaluation where a higher Silhouette Coefficient score relates to a model with better defined clusters The Silhouette Coefficient is defined for each sample and is composed of two scores
•a The mean distance between a sample and all other points in the same class
•b The mean distance between a sample and all other points in the next nearest cluster
The Silhouette Coefficient sfor a single sample is then given as
□□−□
□□□□ □
The Silhouette Coefficient for a set of samples is given as the mean of the Silhouette Coefficient for each sample
```
 from sklearn import metrics
 from sklearnmetrics import pairwisedistances
 from sklearn import datasets
dataset  datasetsloadiris
X  datasetdata
y  datasettarget
```
In normal usage the Silhouette Coefficient is applied to the results of a cluster analysis
```
 import numpy as np
 from sklearncluster import KMeans
kmeansmodel  KMeansnclusters3 randomstate1fitX
labels  kmeansmodellabels
metricssilhouettescoreX labels metriceuclidean
```

• Peter J Rousseeuw 1987 “Silhouettes a Graphical Aid to the Interpretation and Validation of Cluster Analysis” Computational and Applied Mathematics 20 53–65 doi10101603770427879012 57
Advantages
• The score is bounded between 1 for incorrect clustering and 1 for highly dense clustering Scores around zero indicate overlapping clusters
• The score is higher when clusters are dense and well separated which relates to a standard concept of a cluster
Drawbacks
• The Silhouette Coefficient is generally higher for convex clusters than other concepts of clusters such as density based clusters like those obtained through DBSCAN

Examples
•Selecting the number of clusters with silhouette analysis on KMeans clustering In this example the silhouette analysis is used to choose an optimal value for nclusters
CalinskiHarabasz Index
If the ground truth labels are not known the CalinskiHarabasz index sklearnmetrics calinskiharabaszscore also known as the Variance Ratio Criterion can be used to evaluate the model where a higher CalinskiHarabasz score relates to a model with better defined clusters
For□clusters the CalinskiHarabasz score □is given as the ratio of the betweenclusters dispersion mean and the withincluster dispersion
□□ Tr□□
Tr□□×□−□
□−1
where □□is the between group dispersion matrix and □□is the withincluster dispersion matrix defined by
□□□∑

DaviesBouldin Index
If the ground truth labels are not known the DaviesBouldin index sklearnmetrics daviesbouldinscore can be used to evaluate the model where a lower DaviesBouldin index relates to a model with better separation between the clusters
The index is defined as the average similarity between each cluster □□for□ 1 □ and its most similar one □□ In the context of this index similarity is defined as a measure □□□that trades off
•□□ the average distance between each point of cluster □and the centroid of that cluster – also know as cluster diameter
•□□□ the distance between cluster centroids □and□
A simple choice to construct □□□so that it is nonnegative and symmetric is
□□□□□□□
□□□
Then the DaviesBouldin index is defined as
□□1
□□Σ
□1max
⁄□□□□
Zero is the lowest possible score Values closer to zero indicate a better partition
In normal usage the DaviesBouldin index is applied to the results of a cluster analysis as follows
```
 from sklearn import datasets
iris  datasetsloadiris
X  irisdata
 from sklearncluster import KMeans
 from sklearnmetrics import daviesbouldinscore
kmeans  KMeansnclusters3 randomstate1fitX
labels  kmeanslabels
daviesbouldinscoreX labels
```
06619
Advantages
• The computation of DaviesBouldin is simpler than that of Silhouette scores
• The index is computed only quantities and features inherent to the dataset

Drawbacks
• The DaviesBoulding index is generally higher for convex clusters than other concepts of clusters such as density based clusters like those obtained from DBSCAN
• The usage of centroid distance limits the distance metric to Euclidean space
• A good value reported by this method does not imply the best information retrieval

Contingency Matrix
Contingency matrix sklearnmetricsclustercontingencymatrix reports the intersection cardinality for every truepredicted cluster pair The contingency matrix provides sufficient statistics for all clustering metrics where the samples are independent and identically distributed and one doesn’t need to account for some instances not being clustered
Here is an example
```
 from sklearnmetricscluster import contingencymatrix
x  a a a b b b
y  0 0 1 1 2 2
contingencymatrixx y
array2 1 0
0 1 2
```
The first row of output array indicates that there are three samples whose true cluster is “a” Of them two are in predicted cluster 0 one is in 1 and none is in 2 And the second row indicates that there are three samples whose true cluster is “b” Of them none is in predicted cluster 0 one is in 1 and two are in 2
Aconfusion matrix for classification is a square contingency matrix where the order of rows and columns correspond to a list of classes
Advantages
• Allows to examine the spread of each true cluster across predicted clusters and vice versa
• The contingency table calculated is typically utilized in the calculation of a similarity statistic like the others listed in this document between the two clusterings
Drawbacks
• Contingency matrix is easy to interpret for a small number of clusters but becomes very hard to interpret for a large number of clusters

• It doesn’t give a single metric to use as an objective for clustering optimisation
References
• Wikipedia entry for contingency matrix
324 Biclustering
Biclustering can be performed with the module sklearnclusterbicluster Biclustering algorithms simul
taneously cluster rows and columns of a data matrix These clusters of rows and columns are known as biclusters
Each determines a submatrix of the original data matrix with some desired properties
For instance given a matrix of shape 10 10 one possible bicluster with three rows and two columns induces a
submatrix of shape 3 2
 import numpy as np
data nparange100reshape10 10
rows nparray0 2 3 npnewaxis
columns nparray1 2
datarows columns
array 1 2
21 22
31 32
For visualization purposes given a bicluster the rows and columns of the data matrix may be rearranged to make the
bicluster contiguous
Algorithms differ in how they define biclusters Some of the common types include
• constant values constant rows or constant columns
• unusually high or low values
• submatrices with low variance
• correlated rows or columns
Algorithms also differ in how rows and columns may be assigned to biclusters which leads to different bicluster
structures Block diagonal or checkerboard structures occur when rows and columns are divided into partitions
If each row and each column belongs to exactly one bicluster then rearranging the rows and columns of the data matrix
reveals the biclusters on the diagonal Here is an example of this structure where biclusters have higher average values
than the other rows and columns
In the checkerboard case each row belongs to all column clusters and each column belongs to all row clusters Here
is an example of this structure where the variance of the values within each bicluster is small
After fitting a model row and column cluster membership can be found in the rows andcolumns attributes
rowsi is a binary vector with nonzero entries corresponding to rows that belong to bicluster i Similarly
columnsi indicates which columns belong to bicluster i
Some models also have rowlabels andcolumnlabels attributes These models partition the rows and
columns such as in the block diagonal and checkerboard bicluster structures
Note Biclustering has many other names in different fields including coclustering twomode clustering twoway
clustering block clustering coupled twoway clustering etc The names of some algorithms such as the Spectral
CoClustering algorithm reflect these alternate names

Fig 35 An example of biclusters formed by partitioning rows and columns
Fig 36 An example of checkerboard biclusters

Spectral CoClustering

TheSpectralCoclustering algorithm finds biclusters with values higher than those in the corresponding other rows and columns Each row and each column belongs to exactly one bicluster so rearranging the rows and columns to make partitions contiguous reveals these high values along the diagonal

Note The algorithm treats the input data matrix as a bipartite graph the rows and columns of the matrix correspond to the two sets of vertices and each entry corresponds to an edge between a row and a column The algorithm approximates the normalized cut of this graph to find heavy subgraphs

Mathematical formulation

An approximate solution to the optimal normalized cut may be found via the generalized eigenvalue decomposition of the Laplacian of the graph Usually this would mean working directly with the Laplacian matrix If the original data matrix □has shape □×□ the Laplacian matrix for the corresponding bipartite graph has shape □□×□□ However in this case it is possible to work directly with □ which is smaller and more efficient

The input matrix □is preprocessed as follows

□□□−12□□−12

Where □is the diagonal matrix with entry □equal to∑

□□□□and□is the diagonal matrix with entry □equal to∑

□□□□

The singular value decomposition □□□□□⊤ provides the partitions of the rows and columns of □ A subset of the left singular vectors gives the row partitions and a subset of the right singular vectors gives the column partitions

The⌈log2□⌉singular vectors starting from the second provide the desired partitioning information They are used to form the matrix □

□⌈

⌊□−12□

□−12□⌉

⌋

where the columns of □are□2 □ ℓ1 and similarly for □

Then the rows of □are clustered using kmeans The first nrows labels provide the row partitioning and the remainingncolumns labels provide the column partitioning

Examples

•A demo of the Spectral CoClustering algorithm A simple example showing how to generate a data matrix with biclusters and apply this method to it

•Biclustering documents with the Spectral Coclustering algorithm An example of finding biclusters in the twenty newsgroup dataset

References

• Dhillon Inderjit S 2001 Coclustering documents and words using bipartite spectral graph partitioning

Spectral Biclustering
TheSpectralBiclustering algorithm assumes that the input data matrix has a hidden checkerboard structure
The rows and columns of a matrix with this structure may be partitioned so that the entries of any bicluster in the Cartesian product of row clusters and column clusters are approximately constant For instance if there are two row partitions and three column partitions each row will belong to three biclusters and each column will belong to two biclusters
The algorithm partitions the rows and columns of a matrix so that a corresponding blockwiseconstant checkerboard matrix provides a good approximation to the original matrix
Mathematical formulation
The input matrix □is first normalized to make the checkerboard pattern more obvious There are three possible methods
1Independent row and column normalization as in Spectral CoClustering This method makes the rows sum to a constant and the columns sum to a different constant
2Bistochastization repeated row and column normalization until convergence This method makes both rows and columns sum to the same constant
3Log normalization the log of the data matrix is computed □ log □ Then the column mean □□· row mean □·□ and overall mean □··of□are computed The final matrix is computed according to the formula
□□□□□□−□□·−□·□□··
After normalizing the first few singular vectors are computed just as in the Spectral CoClustering algorithm
If log normalization was used all the singular vectors are meaningful However if independent normalization or bistochastization were used the first singular vectors □1and□1 are discarded From now on the “first” singular vectors refers to □2 □ □1and□2 □ □1except in the case of log normalization
Given these singular vectors they are ranked according to which can be best approximated by a piecewiseconstant vector The approximations for each vector are found using onedimensional kmeans and scored using the Euclidean distance Some subset of the best left and right singular vector are selected Next the data is projected to this best subset of singular vectors and clustered
For instance if □singular vectors were calculated the □best are found as described where □ □ Let□be the matrix with columns the □best left singular vectors and similarly □for the right To partition the rows the rows of □are projected to a □dimensional space □□ Treating the □rows of this □×□matrix as samples and clustering using kmeans yields the row labels Similarly projecting the columns to □⊤□and clustering this □×□matrix yields the column labels
Examples
•A demo of the Spectral Biclustering algorithm a simple example showing how to generate a checkerboard matrix and bicluster it
References
• Kluger Yuval et al 2003 Spectral biclustering of microarray data coclustering genes and conditions

Biclustering evaluation
There are two ways of evaluating a biclustering result internal and external Internal measures such as cluster stability rely only on the data and the result themselves Currently there are no internal bicluster measures in scikit learn External measures refer to an external source of information such as the true solution When working with real data the true solution is usually unknown but biclustering artificial data may be useful for evaluating algorithms precisely because the true solution is known
To compare a set of found biclusters to the set of true biclusters two similarity measures are needed a similarity measure for individual biclusters and a way to combine these individual similarities into an overall score
To compare individual biclusters several measures have been used For now only the Jaccard index is implemented
□□ □ □∩□
□□−□∩□
where □and□are biclusters□∩□is the number of elements in their intersection The Jaccard index achieves its minimum of 0 when the biclusters to not overlap at all and its maximum of 1 when they are identical
Several methods have been developed to compare two sets of biclusters For now only consensusscore Hochre iter et al 2010 is available
1 Compute bicluster similarities for pairs of biclusters one in each set using the Jaccard index or a similar measure
2 Assign biclusters from one set to another in a onetoone fashion to maximize the sum of their similarities This step is performed using the Hungarian algorithm
3 The final sum of similarities is divided by the size of the larger set
The minimum consensus score 0 occurs when all pairs of biclusters are totally dissimilar The maximum score 1 occurs when both sets are identical

325 Decomposing signals in components matrix factorization problems
Principal component analysis PCA
Exact PCA and probabilistic interpretation
PCA is used to decompose a multivariate dataset in a set of successive orthogonal components that explain a maximum amount of the variance In scikitlearn PCA is implemented as a transformer object that learns □components in its fit method and can be used on new data to project it on these components
PCA centers but does not scale the input data for each feature before applying the SVD The optional parameter parameterwhitenTrue makes it possible to project the data onto the singular space while scaling each component to unit variance This is often useful if the models downstream make strong assumptions on the isotropy of the signal this is for example the case for Support Vector Machines with the RBF kernel and the KMeans clustering algorithm
Below is an example of the iris dataset which is comprised of 4 features projected on the 2 dimensions that explain most variance
ThePCA object also provides a probabilistic interpretation of the PCA that can give a likelihood of data based on the amount of variance it explains As such it implements a score method that can be used in crossvalidation

Examples
•Comparison of LDA and PCA 2D projection of Iris dataset
•Model selection with Probabilistic PCA and Factor Analysis FA
Incremental PCA
ThePCA object is very useful but has certain limitations for large datasets The biggest limitation is that PCA only sup ports batch processing which means all of the data to be processed must fit in main memory The IncrementalPCA object uses a different form of processing and allows for partial computations which almost exactly match the results ofPCA while processing the data in a minibatch fashion IncrementalPCA makes it possible to implement outof core Principal Component Analysis either by
• Using its partialfit method on chunks of data fetched sequentially from the local hard drive or a network database
• Calling its fit method on a memory mapped file using numpymemmap
IncrementalPCA only stores estimates of component and noise variances in order update explainedvarianceratio incrementally This is why memory usage depends on the number of samples per batch rather than the number of samples to be processed in the dataset
As inPCAIncrementalPCA centers but does not scale the input data for each feature before applying the SVD
Examples
•Incremental PCA
PCA using randomized SVD
It is often interesting to project data to a lowerdimensional space that preserves most of the variance by dropping the singular vector of components associated with lower singular values
For instance if we work with 64x64 pixel graylevel pictures for face recognition the dimensionality of the data is 4096 and it is slow to train an RBF support vector machine on such wide data Furthermore we know that the intrinsic dimensionality of the data is much lower than 4096 since all pictures of human faces look somewhat alike The samples lie on a manifold of much lower dimension say around 200 for instance The PCA algorithm can be used to linearly transform the data while both reducing the dimensionality and preserve most of the explained variance at the same time
The classPCA used with the optional parameter svdsolverrandomized is very useful in that case since we are going to drop most of the singular vectors it is much more efficient to limit the computation to an approximated estimate of the singular vectors we will keep to actually perform the transform
For instance the following shows 16 sample portraits centered around 00 from the Olivetti dataset On the right hand side are the first 16 singular vectors reshaped as portraits Since we only require the top 16 singular vectors of a dataset with size □□□□□□□□ 400 and□□□□□□□□□□ 64×64 4096 the computation time is less than 1s

tions” Halko et al 2009

Kernel PCA
KernelPCA is an extension of PCA which achieves nonlinear dimensionality reduction through the use of kernels see Pairwise metrics Affinities and Kernels It has many applications including denoising compression and structured prediction kernel dependency estimation KernelPCA supports both transform and inversetransform
Examples
•Kernel PCA
Sparse principal components analysis SparsePCA and MiniBatchSparsePCA
SparsePCA is a variant of PCA with the goal of extracting the set of sparse components that best reconstruct the data
Minibatch sparse PCA MiniBatchSparsePCA is a variant of SparsePCA that is faster but less accurate The increased speed is reached by iterating over small chunks of the set of features for a given number of iterations
Principal component analysis PCA has the disadvantage that the components extracted by this method have exclusively dense expressions ie they have nonzero coefficients when expressed as linear combinations of the original variables This can make interpretation difficult In many cases the real underlying components can be more naturally imagined as sparse vectors for example in face recognition components might naturally map to parts of faces
Sparse principal components yields a more parsimonious interpretable representation clearly emphasizing which of the original features contribute to the differences between samples
The following example illustrates 16 components extracted using sparse PCA from the Olivetti faces dataset It can be seen how the regularization term induces many zeros Furthermore the natural structure of the data causes the nonzero coefficients to be vertically adjacent The model does not enforce this mathematically each component is

a vector $h \in R4096$ and there is no notion of vertical adjacency except during the humanfriendly visualization as 64x64 pixel images The fact that the components shown below appear local is the effect of the inherent structure of the data which makes such local patterns minimize reconstruction error There exist sparsityinducing norms that take into account adjacency and different kinds of structure see Jen09 for a review of such methods For more details on how to use Sparse PCA see the Examples section below

Note that there are many different formulations for the Sparse PCA problem The one implemented here is based onMrl09 The optimization problem solved is a PCA problem dictionary learning with an ℓ1penalty on the components

□ □ arg min
□□1
2□−□□2
2□□1
subject to□□2 1for all 0≤□ □ □□□□□□□□□□

The sparsityinducing ℓ1norm also prevents learning components from noise when few training samples are available The degree of penalization and thus sparsity can be adjusted through the hyperparameter alpha Small values lead to a gently regularized factorization while larger values shrink many coefficients to zero

Note While in the spirit of an online algorithm the class MiniBatchSparsePCA does not implement partialfit because the algorithm is online along the features direction not the samples direction

Examples
•Faces dataset decompositions
References
Truncated singular value decomposition and latent semantic analysis
TruncatedSVD implements a variant of singular value decomposition SVD that only computes the largest singular values where is a userspecified parameter
When truncated SVD is applied to termdocument matrices as returned by CountVectorizer or TfidfVectorizer this transformation is known as latent semantic analysis LSA because it transforms such matrices to a “semantic” space of low dimensionality In particular LSA is known to combat the effects of synonymy and polysemy both of which roughly mean there are multiple meanings per word which cause termdocument matrices to be overly sparse and exhibit poor similarity under measures such as cosine similarity
Note LSA is also known as latent semantic indexing LSI though strictly that refers to its use in persistent indexes for information retrieval purposes
Mathematically truncated SVD applied to training samples produces a lowrank approximation
≈
After this operation
is the transformed training set with features called ncomponents in the API
To also transform a test set we multiply it with
′
Note Most treatments of LSA in the natural language processing NLP and information retrieval IR literature swap the axes of the matrix so that it has shape nfeatures ×nsamples We present LSA in a different way that matches the scikitlearn API better but the singular values found are the same
TruncatedSVD is very similar to PCA but differs in that it works on sample matrices directly instead of their covariance matrices When the columnwise perfeature means of are subtracted from the feature values truncated SVD on the resulting matrix is equivalent to PCA In practical terms this means that the TruncatedSVD transformer acceptsscipysparse matrices without the need to densify them as densifying may fill up memory even for mediumsized document collections
While theTruncatedSVD transformer works with any sparse feature matrix using it on tf–idf matrices is recommended over raw frequency counts in an LSAdocument processing setting In particular sublinear scaling and inverse document frequency should be turned on sublineartfTrue useidfTrue to bring the feature values closer to a Gaussian distribution compensating for LSA’s erroneous assumptions about textual data
Examples
•Clustering text documents using kmeans

Dictionary Learning
Sparse coding with a precomputed dictionary
TheSparseCoder object is an estimator that can be used to transform signals into sparse linear combination of
atoms from a fixed precomputed dictionary such as a discrete wavelet basis This object therefore does not implement
afit method The transformation amounts to a sparse coding problem finding a representation of the data as a linear
combination of as few dictionary atoms as possible All variations of dictionary learning implement the following
transform methods controllable via the transformmethod initialization parameter
• Orthogonal matching pursuit Orthogonal Matching Pursuit OMP
• Leastangle regression Least Angle Regression
• Lasso computed by leastangle regression
• Lasso using coordinate descent Lasso
• Thresholding
Thresholding is very fast but it does not yield accurate reconstructions They have been shown useful in literature for
classification tasks For image reconstruction tasks orthogonal matching pursuit yields the most accurate unbiased
reconstruction
The dictionary learning objects offer via the splitcode parameter the possibility to separate the positive and
negative values in the results of sparse coding This is useful when dictionary learning is used for extracting features
that will be used for supervised learning because it allows the learning algorithm to assign different weights to negative
loadings of a particular atom from to the corresponding positive loading
The split code for a single sample has length 2ncomponents and is constructed using the following rule
First the regular code of length ncomponents is computed Then the first ncomponents entries of the
splitcode are filled with the positive part of the regular code vector The second half of the split code is filled
with the negative part of the code vector only with a positive sign Therefore the splitcode is nonnegative
Examples
•Sparse coding with a precomputed dictionary
Generic dictionary learning
Dictionary learning DictionaryLearning is a matrix factorization problem that amounts to finding a usually
overcomplete dictionary that will perform well at sparsely encoding the fitted data
Representing data as sparse combinations of atoms from an overcomplete dictionary is suggested to be the way the
mammalian primary visual cortex works Consequently dictionary learning applied on image patches has been shown
to give good results in image processing tasks such as image completion inpainting and denoising as well as for
supervised recognition tasks

Dictionary learning is an optimization problem solved by alternatively updating the sparse code as a solution to multiple Lasso problems considering the dictionary fixed and then updating the dictionary to best fit the sparse code
□ □ arg min
□□1
2□−□□2
2□□1
subject to□□2 1for all 0≤□ □ atoms
After using such a procedure to fit the dictionary the transform is simply a sparse coding step that shares the same implementation with all dictionary learning objects see Sparse coding with a precomputed dictionary
It is also possible to constrain the dictionary andor code to be positive to match constraints that may be present in the data Below are the faces with different positivity constraints applied Red indicates negative values blue indicates positive values and white represents zeros

scikitlearn user guide Release 0213
32 Unsupervised learning 401

The following image shows how a dictionary learned from 4x4 pixel image patches extracted from part of the image of a raccoon face looks like

Examples

•Image denoising using dictionary learning

References

• “Online dictionary learning for sparse coding” J Mairal F Bach J Ponce G Sapiro 2009

Minibatch dictionary learning

MiniBatchDictionaryLearning implements a faster but less accurate version of the dictionary learning algorithm that is better suited for large datasets

By default MiniBatchDictionaryLearning divides the data into minibatches and optimizes in an online manner by cycling over the minibatches for the specified number of iterations However at the moment it does not implement a stopping condition

The estimator also implements partialfit which updates the dictionary by iterating only once over a minibatch This can be used for online learning when the data is not readily available from the start or for when the data does not fit into the memory

Clustering for dictionary learning

Note that when using dictionary learning to extract a representation eg for sparse coding clustering can be a good proxy to learn the dictionary For instance the MiniBatchKMeans estimator is computationally efficient and implements online learning with a partialfit method

Example Online learning of a dictionary of parts of faces

Factor Analysis

In unsupervised learning we only have a dataset □□1 □2 □ □ How can this dataset be described mathemat ically A very simple continuous latent variable model for □is

□□□*h*□□□

The vector *h*□is called “latent” because it is unobserved □is considered a noise term distributed according to a Gaussian with mean 0 and covariance □ie□~□0□□is some arbitrary offset vector Such a model is called “generative” as it describes how □□is generated from *h*□ If we use all the □□‘s as columns to form a matrix Xand all the*h*□‘s as columns of a matrix Hthen we can write with suitably defined MandE

X□HME

In other words we decomposed matrix X

If*h*□is given the above equation automatically implies the following probabilistic interpretation

□□□*h*□ □□*h*□□□

For a complete probabilistic model we also need a prior distribution for the latent variable *h* The most straightforward assumption based on the nice properties of the Gaussian distribution is *h*~□0I This yields a Gaussian as the marginal distribution of □

□□ □□ □□□ □

Now without any further assumptions the idea of having a latent variable *h*would be superfluous – □can be com pletely modelled with a mean and a covariance We need to impose some more specific structure on one of these two parameters A simple additional assumption regards the structure of the error covariance □

•□ □2I This assumption leads to the probabilistic model of PCA

• diag 1 2 This model is called FactorAnalysis a classical statistical model The matrix
W is sometimes called the “factor loading matrix”
Both models essentially estimate a Gaussian with a lowrank covariance matrix Because both models are probabilistic
they can be integrated in more complex models eg Mixture of Factor Analysers One gets very different models eg
FastICA if nonGaussian priors on the latent variables are assumed
Factor analysis canproduce similar components the columns of its loading matrix to PCA However one can not
make any general statements about these components eg whether they are orthogonal
The main advantage for Factor Analysis over PCA is that it can model the variance in every direction of the input space
independently heteroscedastic noise
This allows better model selection than probabilistic PCA in the presence of heteroscedastic noise
Examples
•Model selection with Probabilistic PCA and Factor Analysis FA

scikitlearn user guide Release 0213

Independent component analysis ICA
Independent component analysis separates a multivariate signal into additive subcomponents that are maximally in dependent It is implemented in scikitlearn using the Fast ICA algorithm Typically ICA is not used for reducing dimensionality but for separating superimposed signals Since the ICA model does not include a noise term for the model to be correct whitening must be applied This can be done internally using the whiten argument or manually using one of the PCA variants
It is classically used to separate mixed signals a problem known as blind source separation as in the example below
ICA can also be used as yet another non linear decomposition that finds components with some sparsity

Examples
•Blind source separation using FastICA
•FastICA on 2D point clouds
•Faces dataset decompositions
Nonnegative matrix factorization NMF or NNMF
NMF with the Frobenius norm
NMF1is an alternative approach to decomposition that assumes that the data and the components are nonnegative NMF can be plugged in instead of PCA or its variants in the cases where the data matrix does not contain negative values It finds a decomposition of samples □into two matrices □and□of nonnegative elements by optimizing the distance □between □and the matrix product □□ The most widely used distance function is the squared Frobenius norm which is an obvious extension of the Euclidean norm to matrices
□Fro□ □ 1
2□−□2
Fro1
2∑
□□□□□−□□□2
UnlikePCA the representation of a vector is obtained in an additive fashion by superimposing the components without subtracting Such additive models are efficient for representing images and text
It has been observed in Hoyer 20042that when carefully constrained NMF can produce a partsbased representation of the dataset resulting in interpretable models The following example displays 16 sparse components found by NMF from the images in the Olivetti faces dataset in comparison with the PCA eigenfaces
1“Learning the parts of objects by nonnegative matrix factorization” D Lee S Seung 1999
2“Nonnegative Matrix Factorization with Sparseness Constraints” P Hoyer 2004

Theinit attribute determines the initialization method applied which has a great impact on the performance of the methodNMF implements the method Nonnegative Double Singular Value Decomposition NNDSVD4is based on two SVD processes one approximating the data matrix the other approximating positive sections of the resulting partial SVD factors utilizing an algebraic property of unit rank matrices The basic NNDSVD algorithm is better fit for sparse factorization Its variants NNDSVDa in which all zeros are set equal to the mean of all elements of the data and NNDSVDar in which the zeros are set to random perturbations less than the mean of the data divided by 100 are recommended in the dense case

Note that the Multiplicative Update 'mu' solver cannot update zeros present in the initialization so it leads to poorer results when used jointly with the basic NNDSVD algorithm which introduces a lot of zeros in this case NNDSVDa or NNDSVDar should be preferred

NMF can also be initialized with correctly scaled random nonnegative matrices by setting initrandom An integer seed or a RandomState can also be passed to randomstate to control reproducibility

InNMF L1 and L2 priors can be added to the loss function in order to regularize the model The L2 prior uses the Frobenius norm while the L1 prior uses an elementwise L1 norm As in ElasticNet we control the combination of L1 and L2 with the l1ratio □ parameter and the intensity of the regularization with the alpha □ parameter Then the priors terms are

NMF regularizes both W and H The public function nonnegativefactorization allows a finer control
through the regularization attribute and may regularize only W only H or both
NMF with a betadivergence
As described previously the most widely used distance function is the squared Frobenius norm which is an obvious
extension of the Euclidean norm to matrices
□Fro□ □ 1
2□−□2
□□□1
2∑
□□□□□−□□□2
Other distance functions can be used in NMF as for example the generalized KullbackLeibler KL divergence
also referred as Idivergence
□□□□ □ ∑
□□□□□log□□□
□□□−□□□□□□
Or the ItakuraSaito IS divergence
□□□□ □ ∑
□□□□□
□□□−log□□□
□□□−1
These three distances are special cases of the betadivergence family with □ 210respectively6 The beta
divergence are defined by
□□□ □ ∑
□□1
□□−1□□
□□ □−1□□
□□−□□□□□□−1
□□
Note that this definition is not valid if □∈0 1 yet it can be continuously extended to the definitions of □□□and
□□□respectively
NMF implements two solvers using Coordinate Descent ‘cd’5 and Multiplicative Update ‘mu’6 The ‘mu’ solver
can optimize every betadivergence including of course the Frobenius norm □ 2 the generalized Kullback
Leibler divergence □ 1 and the ItakuraSaito divergence □ 0 Note that for □∈1 2 the ‘mu’ solver is
significantly faster than for other values of □ Note also that with a negative or 0 ie ‘itakurasaito’ □ the input
matrix cannot contain zero values
The ‘cd’ solver can only optimize the Frobenius norm Due to the underlying nonconvexity of NMF the different
solvers may converge to different minima even when optimizing the same distance function
NMF is best used with the fittransform method which returns the matrix W The matrix H is stored into the
fitted model in the components attribute the method transform will decompose a new matrix Xnew based on
these stored components
```
 import numpy as np
X  nparray1 1 2 1 3 12 4 1 5 08 6 1
 from sklearndecomposition import NMF
model  NMFncomponents2 initrandom randomstate0
```

Latent Dirichlet Allocation LDA
Latent Dirichlet Allocation is a generative probabilistic model for collections of discrete dataset such as text corpora
It is also a topic model that is used for discovering abstract topics from a collection of documents
The graphical model of LDA is a threelevel generative model

Note on notations presented in the graphical model above which can be found in Hoffman et al 2013
• The corpus is a collection of □documents
• A document is a sequence of □words
• There are □topics in the corpus
• The boxes represent repeated sampling
In the graphical model each node is a random variable and has a role in the generative process A shaded node indicates an observed variable and an unshaded node indicates a hidden latent variable In this case words in the corpus are the only data that we observe The latent variables determine the random mixture of topics in the corpus and the distribution of words in the documents The goal of LDA is to use the observed words to infer the hidden topic structure
When modeling text corpora the model assumes the following generative process for a corpus with □documents and □topics with □corresponding to ncomponents in the API
1 For each topic □∈□ draw □□~Dirichlet □ This provides a distribution over the words ie the probability of a word appearing in topic □□corresponds to topicwordprior
2 For each document □∈□ draw the topic proportions □□~Dirichlet □□corresponds to doctopicprior
3 For each word □in document □
1 Draw the topic assignment □□□~Multinomial □□
2 Draw the observed word □□□~Multinomial □□□□
For parameter estimation the posterior distribution is
□□ □ □□ □ □ □□ □ □□ □
□□□ □
Since the posterior is intractable variational Bayesian method uses a simpler distribution □□ □ □□ □ □ to approx imate it and those variational parameters □□□are optimized to maximize the Evidence Lower Bound ELBO
log□□□ □≥□□ □ □ □ △□□log□□ □ □ □□ □−□□log□□ □ □
Maximizing ELBO is equivalent to minimizing the KullbackLeiblerKL divergence between □□ □ □ and the true posterior □□ □ □□ □ □
LatentDirichletAllocation implements the online variational Bayes algorithm and supports both online and batch update methods While the batch method updates variational variables after each full pass through the data the online method updates variational variables from minibatch data points
Note Although the online method is guaranteed to converge to a local optimum point the quality of the optimum point and the speed of convergence may depend on minibatch size and attributes related to learning rate setting

WhenLatentDirichletAllocation is applied on a “documentterm” matrix the matrix will be decomposed into a “topicterm” matrix and a “documenttopic” matrix While “topicterm” matrix is stored as components in the model “documenttopic” matrix can be calculated from transform method
LatentDirichletAllocation also implements partialfit method This is used when data can be fetched sequentially

326 Covariance estimation
Many statistical problems require the estimation of a population’s covariance matrix which can be seen as an estima tion of data set scatter plot shape Most of the time such an estimation has to be done on a sample whose properties size structure homogeneity have a large influence on the estimation’s quality The sklearncovariance pack age provides tools for accurately estimating a population’s covariance matrix under various settings
We assume that the observations are independent and identically distributed iid
Empirical covariance
The covariance matrix of a data set is known to be well approximated by the classical maximum likelihood estimator or “empirical covariance” provided the number of observations is large enough compared to the number of features the variables describing the observations More precisely the Maximum Likelihood Estimator of a sample is an unbiased estimator of the corresponding population’s covariance matrix
The empirical covariance matrix of a sample can be computed using the empiricalcovariance function of the package or by fitting an EmpiricalCovariance object to the data sample with the EmpiricalCovariance fit method Be careful that results depend on whether the data are centered so one may want to use the assumecentered parameter accurately More precisely if assumecenteredFalse then the test set is supposed to have the same mean vector as the training set If not both should be centered by the user and assumecenteredTrue should be used
Examples
• See Shrinkage covariance estimation LedoitWolf vs OAS and maxlikelihood for an example on how to fit an EmpiricalCovariance object to data

Shrunk Covariance
Basic shrinkage
Despite being an unbiased estimator of the covariance matrix the Maximum Likelihood Estimator is not a good esti
mator of the eigenvalues of the covariance matrix so the precision matrix obtained from its inversion is not accurate
Sometimes it even occurs that the empirical covariance matrix cannot be inverted for numerical reasons To avoid
such an inversion problem a transformation of the empirical covariance matrix has been introduced the shrinkage
In scikitlearn this transformation with a userdefined shrinkage coefficient can be directly applied to a precomputed
covariance with the shrunkcovariance method Also a shrunk estimator of the covariance can be fitted to data
with aShrunkCovariance object and its ShrunkCovariancefit method Again results depend on whether
the data are centered so one may want to use the assumecentered parameter accurately
Mathematically this shrinkage consists in reducing the ratio between the smallest and the largest eigenvalues of the
empirical covariance matrix It can be done by simply shifting every eigenvalue according to a given offset which is
equivalent of finding the l2penalized Maximum Likelihood Estimator of the covariance matrix In practice shrinkage
boils down to a simple a convex transformation shrunk 1− TrΣ
Id
Choosing the amount of shrinkage amounts to setting a biasvariance tradeoff and is discussed below
Examples
• See Shrinkage covariance estimation LedoitWolf vs OAS and maxlikelihood for an example on how to fit a
ShrunkCovariance object to data
LedoitWolf shrinkage
In their 2004 paper1 O Ledoit and M Wolf propose a formula to compute the optimal shrinkage coefficient that
minimizes the Mean Squared Error between the estimated and the real covariance matrix
The LedoitWolf estimator of the covariance matrix can be computed on a sample with the ledoitwolf function
of thesklearncovariance package or it can be otherwise obtained by fitting a LedoitWolf object to the
same sample
Note Case when population covariance matrix is isotropic
It is important to note that when the number of samples is much larger than the number of features one would expect
that no shrinkage would be necessary The intuition behind this is that if the population covariance is full rank when
the number of sample grows the sample covariance will also become positive definite As a result no shrinkage would
necessary and the method should automatically do this
This however is not the case in the LedoitWolf procedure when the population covariance happens to be a multiple of
the identity matrix In this case the LedoitWolf shrinkage estimate approaches 1 as the number of samples increases
This indicates that the optimal estimate of the covariance matrix in the LedoitWolf sense is multiple of the identity
Since the population covariance is already a multiple of the identity matrix the LedoitWolf solution is indeed a
reasonable estimate

Sparse inverse covariance

The matrix inverse of the covariance matrix often called the precision matrix is proportional to the partial correlation matrix It gives the partial independence relationship In other words if two features are independent conditionally on the others the corresponding coefficient in the precision matrix will be zero This is why it makes sense to estimate a sparse precision matrix the estimation of the covariance matrix is better conditioned by learning independence relations from the data This is known as covariance selection

In the smallsamples situation in which nsamples is on the order of nfeatures or smaller sparse inverse covariance estimators tend to work better than shrunk covariance estimators However in the opposite situation or for very correlated data they can be numerically unstable In addition unlike shrinkage estimators sparse estimators are able to recover offdiagonal structure

TheGraphicalLasso estimator uses an l1 penalty to enforce sparsity on the precision matrix the higher its alpha parameter the more sparse the precision matrix The corresponding GraphicalLassoCV object uses crossvalidation to automatically set the alpha parameter

Note Structure recovery

Recovering a graphical structure from correlations in the data is a challenging thing If you are interested in such recovery keep in mind that

• Recovery is easier from a correlation matrix than a covariance matrix standardize your observations before runningGraphicalLasso

• If the underlying graph has nodes with much more connections than the average node the algorithm will miss some of these connections

Fig 38 A comparison of maximum likelihood shrinkage and sparse estimates of the covariance and precision matrix in the very small samples settings
• If your number of observations is not large compared to the number of edges in your underlying graph you will not recover it
• Even if you are in favorable recovery conditions the alpha parameter chosen by crossvalidation eg using the GraphicalLassoCV object will lead to selecting too many edges However the relevant edges will have heavier weights than the irrelevant ones
The mathematical formulation is the following
□ argmin□
tr□□−logdet □□‖□‖1
Where □is the precision matrix to be estimated and □is the sample covariance matrix ‖□‖1is the sum of the absolute values of offdiagonal coefficients of □ The algorithm employed to solve this problem is the GLasso algorithm from the Friedman 2008 Biostatistics paper It is the same algorithm as in the R glasso package
Examples

Robust Covariance Estimation
Real data sets are often subject to measurement or recording errors Regular but uncommon observations may also appear for a variety of reasons Observations which are very uncommon are called outliers The empirical covariance estimator and the shrunk covariance estimators presented above are very sensitive to the presence of outliers in the data Therefore one should use robust covariance estimators to estimate the covariance of its real data sets Alternatively robust covariance estimators can be used to perform outlier detection and discarddownweight some observations according to further processing of the data
Thesklearncovariance package implements a robust estimator of covariance the Minimum Covariance De terminant3
Minimum Covariance Determinant
The Minimum Covariance Determinant estimator is a robust estimator of a data set's covariance introduced by PJ Rousseeuw in3 The idea is to find a given proportion h of "good" observations which are not outliers and compute their empirical covariance matrix This empirical covariance matrix is then rescaled to compensate the performed selection of observations "consistency step" Having computed the Minimum Covariance Determinant estimator one can give weights to observations according to their Mahalanobis distance leading to a reweighted estimate of the covariance matrix of the data set "reweighting step"
Rousseeuw and Van Driessen4developed the FastMCD algorithm in order to compute the Minimum Covariance Determinant This algorithm is used in scikitlearn when fitting an MCD object to data The FastMCD algorithm also computes a robust estimate of the data set location at the same time
Raw estimates can be accessed as rawlocation andrawcovariance attributes of a MinCovDet robust covariance estimator object
References
Examples

Influence of outliers on location and covariance
estimatesSeparating inliers from outliers using a Mahalanobis
distance
327 Novelty and Outlier Detection
Many applications require being able to decide whether a new observation belongs to the same distribution as existing observations it is an inlier or should be considered as different it is an outlier Often this ability is used to clean real data sets Two important distinctions must be made
outlier detection The training data contains outliers which are defined as observations that are far from the others Outlier detection estimators thus try to fit the regions where the training data is the most concentrated ignoring the deviant observations
novelty detection The training data is not polluted by outliers and we are interested in detecting whether anew observation is an outlier In this context an outlier is also called a novelty
Outlier detection and novelty detection are both used for anomaly detection where one is interested in detecting abnormal or unusual observations Outlier detection is then also known as unsupervised anomaly detection and novelty detection as semisupervised anomaly detection In the context of outlier detection the outliersanomalies cannot form a dense cluster as available estimators assume that the outliersanomalies are located in low density regions On the contrary in the context of novelty detection noveltiesanomalies can form a dense cluster as long as they are in a low density region of the training data considered as normal in this context
The scikitlearn project provides a set of machine learning tools that can be used both for novelty or outlier detection This strategy is implemented with objects learning in an unsupervised way from the data
estimatorfitXtrain
new observations can then be sorted as inliers or outliers with a predict method
estimatorpredictXtest
Inliers are labeled 1 while outliers are labeled 1 The predict method makes use of a threshold on the raw scoring function computed by the estimator This scoring function is accessible through the scoresamples method while the threshold can be controlled by the contamination parameter
Thedecisionfunction method is also defined from the scoring function in such a way that negative values are outliers and nonnegative ones are inliers
estimatordecisionfunctionXtest

Note that neighborsLocalOutlierFactor does not support predict decisionfunction and
scoresamples methods by default but only a fitpredict method as this estimator was originally meant
to be applied for outlier detection The scores of abnormality of the training samples are accessible through the
negativeoutlierfactor attribute
If you really want to use neighborsLocalOutlierFactor for novelty detection ie predict labels or compute
the score of abnormality of new unseen data you can instantiate the estimator with the novelty parameter set to
True before fitting the estimator In this case fitpredict is not available
Warning Novelty detection with Local Outlier Factor
Whennovelty is set toTrue be aware that you must only use predict decisionfunction
andscoresamples on new unseen data and not on the training samples as this would lead to
wrong results The scores of abnormality of the training samples are always accessible through the
negativeoutlierfactor attribute
The behavior of neighborsLocalOutlierFactor is summarized in the following table
Method Outlier detection Novelty detection
fitpredict OK Not available
predict Not available Use only on new data
decisionfunction Not available Use only on new data
scoresamples Usenegativeoutlierfactor Use only on new data
Overview of outlier detection methods
A comparison of the outlier detection algorithms in scikitlearn Local Outlier Factor LOF does not show a decision
boundary in black as it has no predict method to be applied on new data when it is used for outlier detection
ensembleIsolationForest andneighborsLocalOutlierFactor perform reasonably well on the
data sets considered here The svmOneClassSVM is known to be sensitive to outliers and thus does not perform
very well for outlier detection Finally covarianceEllipticEnvelope assumes the data is Gaussian and
learns an ellipse For more details on the different estimators refer to the example Comparing anomaly detection
algorithms for outlier detection on toy datasets and the sections hereunder
Examples
• See Comparing anomaly detection algorithms for outlier detection on toy datasets for a com
parison of the svmOneClassSVM theensembleIsolationForest theneighbors
LocalOutlierFactor andcovarianceEllipticEnvelope
Novelty Detection
Consider a data set of observations from the same distribution described by features Consider now that we add one
more observation to that data set Is the new observation so different from the others that we can doubt it is regular
ie does it come from the same distribution Or on the contrary is it so similar to the other that we cannot distinguish
it from the original observations This is the question addressed by the novelty detection tools and methods
In general it is about to learn a rough close frontier delimiting the contour of the initial observations distribution
plotted in embedding dimensional space Then if further observations lay within the frontierdelimited subspace

they are considered as coming from the same population than the initial observations Otherwise if they lay outside the frontier we can say that they are abnormal with a given confidence in our assessment
The OneClass SVM has been introduced by Schölkopf et al for that purpose and implemented in the Support Vector Machines module in the svmOneClassSVM object It requires the choice of a kernel and a scalar parameter to define a frontier The RBF kernel is usually chosen although there exists no exact formula or algorithm to set its bandwidth parameter This is the default in the scikitlearn implementation The parameter also known as the margin of the OneClass SVM corresponds to the probability of finding a new but regular observation outside the frontier

•Species distribution modeling
Outlier Detection
Outlier detection is similar to novelty detection in the sense that the goal is to separate a core of regular observations from some polluting ones called outliers Yet in the case of outlier detection we don’t have a clean data set representing the population of regular observations that can be used to train any tool

Fitting an elliptic envelope
One common way of performing outlier detection is to assume that the regular data come from a known distribution eg data are Gaussian distributed From this assumption we generally try to define the “shape” of the data and can define outlying observations as observations which stand far enough from the fit shape
The scikitlearn provides an object covarianceEllipticEnvelope that fits a robust covariance estimate to the data and thus fits an ellipse to the central data points ignoring points outside the central mode
For instance assuming that the inlier data are Gaussian distributed it will estimate the inlier location and covariance in a robust way ie without being influenced by outliers The Mahalanobis distances obtained from this estimate is used to derive a measure of outlyingness This strategy is illustrated below
Examples
• See Robust covariance estimation and Mahalanobis distances relevance for an illustration of the dif ference between using a standard covarianceEmpiricalCovariance or a robust estimate covarianceMinCovDet of location and covariance to assess the degree of outlyingness of an ob servation

Isolation Forest

One efficient way of performing outlier detection in highdimensional datasets is to use random forests The ensembleIsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature

Since recursive partitioning can be represented by a tree structure the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node

This path length averaged over a forest of such random trees is a measure of normality and our decision function Random partitioning produces noticeably shorter paths for anomalies Hence when a forest of random trees collectively produce shorter path lengths for particular samples they are highly likely to be anomalies

The implementation of ensembleIsolationForest is based on an ensemble of tree ExtraTreeRegressor Following Isolation Forest original paper the maximum depth of each tree is set to⌈log2□⌉where □is the number of samples used to build the tree see Liu et al 2008 for more details

This algorithm is illustrated below The ensembleIsolationForest supportswarmstartTrue which allows you to add more trees to an already fitted model

```
 from sklearnensemble import IsolationForest
 import numpy as np
X  nparray1 1 2 1 3 2 0 0 20 50 3 5
clf  IsolationForestnestimators10 warmstart True
clffitX  fit 10 trees
clfsetparamsnestimators20  add 10 more trees
clffitX  fit the added trees
```

Local Outlier Factor
Another efficient way to perform outlier detection on moderately high dimensional datasets is to use the Local Outlier Factor LOF algorithm
TheneighborsLocalOutlierFactor LOF algorithm computes a score called local outlier factor reflecting the degree of abnormality of the observations It measures the local density deviation of a given data point with respect to its neighbors The idea is to detect the samples that have a substantially lower density than their neighbors In practice the local density is obtained from the knearest neighbors The LOF score of an observation is equal to the ratio of the average local density of his knearest neighbors and its own local density a normal instance is expected to have a local density similar to that of its neighbors while abnormal data are expected to have much smaller local density
The number k of neighbors considered alias parameter nneighbors is typically chosen 1 greater than the minimum number of objects a cluster has to contain so that other objects can be local outliers relative to this cluster and 2 smaller than the maximum number of close by objects that can potentially be local outliers In practice such informations are generally not available and taking nneighbors20 appears to work well in general When the proportion of outliers is high ie greater than 10 as in the example below nneighbors should be greater nneighbors35 in the example below
The strength of the LOF algorithm is that it takes both local and global properties of datasets into consideration it can perform well even in datasets where abnormal samples have different underlying densities The question is not how isolated the sample is but how isolated it is with respect to the surrounding neighborhood
When applying LOF for outlier detection there are no predict decisionfunction andscoresamples methods but only a fitpredict method The scores of abnormality of the training samples are accessible through the negativeoutlierfactor attribute Note that predict decisionfunction and scoresamples can be used on new unseen data when LOF is applied for novelty detection ie when the novelty parameter is set to True See Novelty detection with Local Outlier Factor
This strategy is illustrated below
Examples
• See Outlier detection with Local Outlier Factor LOF for an illustration of the use of neighbors LocalOutlierFactor
• See Comparing anomaly detection algorithms for outlier detection on toy datasets for a comparison with other anomaly detection methods

scikitlearn user guide Release 0213
328 Density Estimation
Density estimation walks the line between unsupervised learning feature engineering and data modeling Some of the most popular and useful density estimation techniques are mixture models such as Gaussian Mixtures sklearn mixtureGaussianMixture and neighborbased approaches such as the kernel density estimate sklearn neighborsKernelDensity Gaussian Mixtures are discussed more fully in the context of clustering because the technique is also useful as an unsupervised clustering scheme
Density estimation is a very simple concept and most people are already familiar with one common density estimation technique the histogram
Density Estimation Histograms
A histogram is a simple visualization of data where bins are defined and the number of data points within each bin is tallied An example of a histogram can be seen in the upperleft panel of the following figure
426 Chapter 3 User Guide

A major problem with histograms however is that the choice of binning can have a disproportionate effect on the resulting visualization Consider the upperright panel of the above figure It shows a histogram over the same data with the bins shifted right The results of the two visualizations look entirely different and might lead to different interpretations of the data
Intuitively one can also think of a histogram as a stack of blocks one block per point By stacking the blocks in the appropriate grid space we recover the histogram But what if instead of stacking the blocks on a regular grid we center each block on the point it represents and sum the total height at each location This idea leads to the lowerleft visualization It is perhaps not as clean as a histogram but the fact that the data drive the block locations mean that it is a much better representation of the underlying data
This visualization is an example of a kernel density estimation in this case with a tophat kernel ie a square block at each point We can recover a smoother distribution by using a smoother kernel The bottomright plot shows a Gaussian kernel density estimate in which each point contributes a Gaussian curve to the total The result is a smooth density estimate which is derived from the data and functions as a powerful nonparametric model of the distribution of points
Kernel Density Estimation
Kernel density estimation in scikitlearn is implemented in the sklearnneighborsKernelDensity esti mator which uses the Ball Tree or KD Tree for efficient queries see Nearest Neighbors for a discussion of these
Though the above example uses a 1D data set for simplicity kernel density estimation can be performed in any number of dimensions though in practice the curse of dimensionality causes its performance to degrade in high dimensions
In the following figure 100 points are drawn from a bimodal distribution and the kernel density estimates are shown for three choices of kernels

It’s clear how the kernel shape affects the smoothness of the resulting distribution The scikitlearn kernel density estimator can be used as follows

```
 from sklearnneighborskde import KernelDensity
 import numpy as np
X  nparray1 1 2 1 3 2 1 1 2 1 3 2
kde  KernelDensitykernelgaussian bandwidth02fitX
kdescoresamplesX
array041075698 041075698 041076071 041075698 041075698
041076071
```

Here we have used kernelgaussian as seen above Mathematically a kernel is a positive function □□*h* which is controlled by the bandwidth parameter *h* Given this kernel form the density estimate at a point □within a group of points □□□ 1⋯□is given by

□□□ □∑
□1□□−□□*h*

The bandwidth here acts as a smoothing parameter controlling the tradeoff between bias and variance in the result A large bandwidth leads to a very smooth ie highbias density distribution A small bandwidth leads to an unsmooth ie highvariance density distribution

sklearnneighborsKernelDensity implements several common kernel forms which are shown in the following figure

The form of these kernels is as follows
• Gaussian kernel kernel gaussian
□□*h*∝exp−□2
2*h*2
• Tophat kernel kernel tophat
□□*h*∝1if□ *h*
• Epanechnikov kernel kernel epanechnikov
□□*h*∝1−□2
*h*2
• Exponential kernel kernel exponential
□□*h*∝exp−□*h*
• Linear kernel kernel linear
□□*h*∝1−□*h* if□ *h*
• Cosine kernel kernel cosine
□□*h*∝cos□□
2*h*if□ *h*
The kernel density estimator can be used with any of the valid distance metrics see sklearnneighbors DistanceMetric for a list of available metrics though the results are properly normalized only for the Euclidean metric One particularly useful metric is the Haversine distance which measures the angular distance between points on a sphere Here is an example of using a kernel density estimate for a visualization of geospatial data in this case the distribution of observations of two different species on the South American continent

One other useful application of kernel density estimation is to learn a nonparametric generative model of a dataset in order to efficiently draw new samples from this generative model Here is an example of using this process to create a new set of handwritten digits using a Gaussian kernel learned on a PCA projection of the data
The “new” data consists of linear combinations of the input data with weights probabilistically drawn given the KDE model

Examples
•Simple 1D Kernel Density Estimation computation of simple kernel density estimates in one dimension
•Kernel Density Estimation an example of using Kernel Density estimation to learn a generative model of the handwritten digits data and drawing new samples from this model
•Kernel Density Estimate of Species Distributions an example of Kernel Density estimation using the Haversine distance metric to visualize geospatial data
329 Neural network models unsupervised
Restricted Boltzmann machines
Restricted Boltzmann machines RBM are unsupervised nonlinear feature learners based on a probabilistic model The features extracted by an RBM or a hierarchy of RBMs often give good results when fed into a linear classifier such as a linear SVM or a perceptron
The model makes assumptions regarding the distribution of inputs At the moment scikitlearn only provides BernoulliRBM which assumes the inputs are either binary values or values between 0 and 1 each encoding the probability that the specific feature would be turned on
The RBM tries to maximize the likelihood of the data using a particular graphical model The parameter learning algorithm used Stochastic Maximum Likelihood prevents the representations from straying far from the input data which makes them capture interesting regularities but makes the model less useful for small datasets and usually not useful for density estimation
The method gained popularity for initializing deep neural networks with the weights of independent RBMs This method is known as unsupervised pretraining
Examples
•Restricted Boltzmann Machine features for digit classification
Graphical model and parametrization
The graphical model of an RBM is a fullyconnected bipartite graph

The nodes are random variables whose states depend on the state of the other nodes they are connected to The model is therefore parameterized by the weights of the connections as well as one intercept bias term for each visible and hidden unit omitted from the image for simplicity

The energy function measures the quality of a joint assignment

□vh −∑

□∑

□□□□□□*h*□−∑

□□□□□−∑

□□□*h*□

In the formula above bandcare the intercept vectors for the visible and hidden layers respectively The joint

probability of the model is defined in terms of the energy
□vh □−□vh
□
The word restricted refers to the bipartite structure of the model which prohibits direct interaction between hidden units or between visible units This means that the following conditional independencies are assumed
h□⊥*h*□v
□□⊥□□h
The bipartite structure allows for the use of efficient block Gibbs sampling for inference
Bernoulli Restricted Boltzmann machines
In theBernoulliRBM all units are binary stochastic units This means that the input data should either be binary or realvalued between 0 and 1 signifying the probability that the visible unit would turn on or off This is a good model for character recognition where the interest is on which pixels are active and which aren't For images of natural scenes it no longer fits because of background depth and the tendency of neighbouring pixels to take the same values
The conditional probability distribution of each unit is given by the logistic sigmoid activation function of the input it receives
□□□ 1h □∑
□□□□*h*□□□
□*h*□ 1v □∑
□□□□□□□□
where □is the logistic sigmoid function
□□ 1
1 □−□
Stochastic Maximum Likelihood learning
The training algorithm implemented in BernoulliRBM is known as Stochastic Maximum Likelihood SML or Persistent Contrastive Divergence PCD Optimizing maximum likelihood directly is infeasible because of the form of the data likelihood
log□□ log∑
h□−□□*h*−log∑
□□□−□□□
For simplicity the equation above is written for a single training example The gradient with respect to the weights is formed of two terms corresponding to the ones above They are usually known as the positive gradient and the negative gradient because of their respective signs In this implementation the gradients are estimated over minibatches of samples
In maximizing the loglikelihood the positive gradient makes the model prefer hidden states that are compatible with the observed training data Because of the bipartite structure of RBMs it can be computed efficiently The negative gradient however is intractable Its goal is to lower the energy of joint states that the model prefers therefore making it stay true to the data It can be approximated by Markov chain Monte Carlo using block Gibbs sampling by iteratively sampling each of □and*h*given the other until the chain mixes Samples generated in this way are sometimes referred as fantasy particles This is inefficient and it is difficult to determine whether the Markov chain mixes
The Contrastive Divergence method suggests to stop the chain after a small number of iterations □ usually even 1 This method is fast and has low variance but the samples are far from the model distribution

Persistent Contrastive Divergence addresses this Instead of starting a new chain each time the gradient is needed and performing only one Gibbs sampling step in PCD we keep a number of chains fantasy particles that are updated Gibbs steps after each weight update This allows the particles to explore the space more thoroughly

33 Model selection and evaluation

331 Crossvalidation evaluating estimator performance

Learning the parameters of a prediction function and testing it on the same data is a methodological mistake a model that would just repeat the labels of the samples that it has just seen would have a perfect score but would fail to predict anything useful on yetunseen data This situation is called overfitting To avoid it it is common practice when performing a supervised machine learning experiment to hold out part of the available data as a test setXtest ytest Note that the word “experiment” is not intended to denote academic use only because even in commercial settings machine learning usually starts out experimentally Here is a flowchart of typical cross validation workflow in model training The best parameters can be determined by grid search techniques

In scikitlearn a random split into training and test sets can be quickly computed with the traintestsplit helper function Let’s load the iris data set to fit a linear support vector machine on it

```
 import numpy as np
 from sklearnmodelselection import traintestsplit
 from sklearn import datasets
 from sklearn import svm
iris  datasetsloadiris
irisdatashape iristargetshape
150 4 150
```

We can now quickly sample a training set while holding out 40 of the data for testing evaluating our classifier

```
Xtrain Xtest ytrain ytest  traintestsplit
 irisdata iristarget testsize04 randomstate0
Xtrainshape ytrainshape
90 4 90
Xtestshape ytestshape
60 4 60
clf  svmSVCkernellinear C1fitXtrain ytrain
clfscoreXtest ytest
096
```
When evaluating different settings “hyperparameters” for estimators such as the Csetting that must be manually set for an SVM there is still a risk of overfitting on the test set because the parameters can be tweaked until the estimator performs optimally This way knowledge about the test set can “leak” into the model and evaluation metrics no longer report on generalization performance To solve this problem yet another part of the dataset can be held out as a so called “validation set” training proceeds on the training set after which evaluation is done on the validation set and when the experiment seems to be successful final evaluation can be done on the test set

However by partitioning the available data into three sets we drastically reduce the number of samples which can be used for learning the model and the results can depend on a particular random choice for the pair of train validation sets

A solution to this problem is a procedure called crossvalidation CV for short A test set should still be held out for final evaluation but the validation set is no longer needed when doing CV In the basic approach called kfold CV the training set is split into ksmaller sets other approaches are described below but generally follow the same principles

The following procedure is followed for each of the k“folds”

• A model is trained using −1of the folds as training data

• the resulting model is validated on the remaining part of the data ie it is used as a test set to compute a performance measure such as accuracy

The performance measure reported by kfold crossvalidation is then the average of the values computed in the loop This approach can be computationally expensive but does not waste too much data as is the case when fixing an arbitrary validation set which is a major advantage in problems such as inverse inference where the number of samples is very small

Computing crossvalidated metrics
The simplest way to use crossvalidation is to call the crossvalscore helper function on the estimator and the dataset
The following example demonstrates how to estimate the accuracy of a linear kernel support vector machine on the iris dataset by splitting the data fitting a model and computing the score 5 consecutive times with different splits each time
```
 from sklearnmodelselection import crossvalscore
clf  svmSVCkernellinear C1
scores  crossvalscoreclf irisdata iristarget cv5
scores
array096 1  096 096 1
```
The mean score and the 95 confidence interval of the score estimate are hence given by
```
printAccuracy 02f02f  scoresmean scoresstd 2
Accuracy 098  003
```
By default the score computed at each CV iteration is the score method of the estimator It is possible to change this by using the scoring parameter
```
 from sklearn import metrics
scores  crossvalscore
 clf irisdata iristarget cv5 scoringf1macro
scores
array096 1  096 096 1
```
SeeThe scoring parameter defining model evaluation rules for details In the case of the Iris dataset the samples are balanced across target classes hence the accuracy and the F1score are almost equal
When thecvargument is an integer crossvalscore uses theKFold orStratifiedKFold strategies by default the latter being used if the estimator derives from ClassifierMixin
It is also possible to use other cross validation strategies by passing a cross validation iterator instead for instance
```
 from sklearnmodelselection import ShuffleSplit
nsamples  irisdatashape0
cv  ShuffleSplitnsplits5 testsize03 randomstate0
crossvalscoreclf irisdata iristarget cvcv
array0977 0977 1  0955 1
```
Another option is to use an iterable yielding train test splits as arrays of indices for example
```
 def customcv2foldsX
 n  Xshape0
 i  1
 while i  2
 idx  nparangen i  1  2 n i  2 dtypeint
 yield idx idx
 i  1

customcv  customcv2foldsirisdata
crossvalscoreclf irisdata iristarget cvcustomcv
array1  0973
```

Data transformation with held out data
Just as it is important to test a predictor on data heldout from training preprocessing such as standardization feature selection etc and similar data transformations similarly should be learnt from a training set and applied to heldout data for prediction

```
 from sklearn import preprocessing
Xtrain Xtest ytrain ytest  traintestsplit
 irisdata iristarget testsize04 randomstate0
scaler  preprocessingStandardScalerfitXtrain
Xtraintransformed  scalertransformXtrain
clf  svmSVCC1fitXtraintransformed ytrain
Xtesttransformed  scalertransformXtest
clfscoreXtesttransformed ytest
```

09333
APipeline makes it easier to compose estimators providing this behavior under crossvalidation

```
 from sklearnpipeline import makepipeline
clf  makepipelinepreprocessingStandardScaler svmSVCC1
crossvalscoreclf irisdata iristarget cvcv

array0977 0933 0955 0933 0977
```

SeePipelines and composite estimators
The crossvalidate function and multiple metric evaluation
Thecrossvalidate function differs from crossvalscore in two ways
• It allows specifying multiple metrics for evaluation
• It returns a dict containing fittimes scoretimes and optionally training scores as well as fitted estimators in addition to the test score
For single metric evaluation where the scoring parameter is a string callable or None the keys will be
testscore fittime scoretime
And for multiple metric evaluation the return value is a dict with the following keys
testscorer1name testscorer2name testscorer fittime
scoretime
returntrainscore is set toFalse by default to save computation time To evaluate the scores on the training set as well you need to be set to True
You may also retain the estimator fitted on each training set by setting returnestimatorTrue
The multiple metrics can be specified either as a list tuple or set of predefined scorer names

```
 from sklearnmodelselection import crossvalidate
 from sklearnmetrics import recallscore
scoring  precisionmacro recallmacro
clf  svmSVCkernellinear C1 randomstate0
scores  crossvalidateclf irisdata iristarget scoringscoring
 cv5
sortedscoreskeys
fittime scoretime testprecisionmacro testrecallmacro
scorestestrecallmacro
array096 1  096 096 1
```

Or as a dict mapping scorer name to a predefined or custom scoring function
```
 from sklearnmetricsscorer import makescorer
scoring  precmacro precisionmacro
 recmacro makescorerrecallscore averagemacro
scores  crossvalidateclf irisdata iristarget scoringscoring
 cv5 returntrainscore True
sortedscoreskeys
fittime scoretime testprecmacro testrecmacro
trainprecmacro trainrecmacro
scorestrainrecmacro
array097 097 099 098 098
```
Here is an example of crossvalidate using a single metric
```
scores  crossvalidateclf irisdata iristarget
 scoringprecisionmacro cv5
 returnestimator True
sortedscoreskeys
estimator fittime scoretime testscore
```
Obtaining predictions by crossvalidation

The function crossvalpredict has a similar interface to crossvalscore but returns for each element in the input the prediction that was obtained for that element when it was in the test set Only crossvalidation strategies that assign all elements to a test set exactly once can be used otherwise an exception is raised

Warning Note on inappropriate usage of crossvalpredict

The result of crossvalpredict may be different from those obtained using crossvalscore as the elements are grouped in different ways The function crossvalscore takes an average over crossvalidation folds whereas crossvalpredict simply returns the labels or probabilities from several distinct models undistinguished Thus crossvalpredict is not an appropriate measure of generalisation error

The function crossvalpredict is appropriate for

• Visualization of predictions obtained from different models

• Model blending When predictions of one supervised estimator are used to train another estimator in ensemble methods

The available cross validation iterators are introduced in the following section

Examples

•Receiver Operating Characteristic ROC with cross validation

•Recursive feature elimination with crossvalidation

•Parameter estimation using grid search with crossvalidation

•Sample pipeline for text feature extraction and evaluation

•Plotting CrossValidated Predictions

•Nested versus nonnested crossvalidation

Cross validation iterators
The following sections list utilities to generate indices that can be used to generate dataset splits according to different cross validation strategies
Crossvalidation iterators for iid data
Assuming that some data is Independent and Identically Distributed iid is making the assumption that all samples stem from the same generative process and that the generative process is assumed to have no memory of past generated samples
The following crossvalidators can be used in such cases
NOTE
While iid data is a common assumption in machine learning theory it rarely holds in practice If one knows that the samples have been generated using a timedependent process it’s safer to use a timeseries aware crossvalidation scheme Similarly if we know that the generative process has a group structure samples from collected from different subjects experiments measurement devices it safer to use groupwise crossvalidation
Kfold
KFold divides all the samples in groups of samples called folds if this is equivalent to the Leave One Out strategy of equal sizes if possible The prediction function is learned using folds and the fold left out is used for test
Example of 2fold crossvalidation on a dataset with 4 samples
```
 import numpy as np
 from sklearnmodelselection import KFold
X  a b c d
kf  KFoldnsplits2
 for train test inkfsplitX
 prints s  train test
2 3 0 1
0 1 2 3
```
Here is a visualization of the crossvalidation behavior Note that KFold is not affected by classes or groups

Each fold is constituted by two arrays the first one is related to the training set and the second one to the test set
Thus one can create the trainingtest sets using numpy indexing
X nparray0 0 1 1 1 1 2 2
y nparray0 1 0 1
Xtrain Xtest ytrain ytest Xtrain Xtest ytrain ytest
Repeated KFold
RepeatedKFold repeats KFold n times It can be used when one requires to run KFold n times producing
different splits in each repetition
Example of 2fold KFold repeated 2 times
import numpy as np
from sklearnmodelselection import RepeatedKFold
X nparray1 2 3 4 1 2 3 4
randomstate 12883823
rkf RepeatedKFoldnsplits2 nrepeats2 randomstaterandomstate
for train test inrkfsplitX
prints s train test

2 3 0 1
0 1 2 3
0 2 1 3
1 3 0 2
SimilarlyRepeatedStratifiedKFold repeats Stratified KFold n times with different randomization in each
repetition
Leave One Out LOO
LeaveOneOut or LOO is a simple crossvalidation Each learning set is created by taking all the samples except
one the test set being the sample left out Thus for samples we have different training sets and different tests
set This crossvalidation procedure does not waste much data as only one sample is removed from the training set
from sklearnmodelselection import LeaveOneOut
X 1 2 3 4
loo LeaveOneOut
for train test inloosplitX
prints s train test
1 2 3 0
0 2 3 1
0 1 3 2
0 1 2 3
Potential users of LOO for model selection should weigh a few known caveats When compared with fold cross
validation one builds models from samples instead of models where Moreover each is trained on −1
samples rather than −1 In both ways assuming is not too large and LOO is more computationally
expensive than fold cross validation
In terms of accuracy LOO often results in high variance as an estimator for the test error Intuitively since −1of
the samples are used to build each model models constructed from folds are virtually identical to each other and to
the model built from the entire training set

However if the learning curve is steep for the training size in question then 5 or 10 fold cross validation can overestimate the generalization error
As a general rule most authors and empirical evidence suggest that 5 or 10 fold cross validation should be preferred to LOO

Leave P Out LPO
LeavePOut is very similar to LeaveOneOut as it creates all the possible trainingtest sets by removing samples from the complete set For samples this produces
traintest pairs Unlike LeaveOneOut andKFold the test sets will overlap for 1
Example of Leave2Out on a dataset with 4 samples
```
from sklearnmodelselection import LeavePOut
X  npones4
lpo  LeavePOutp2
for train test inlposplitX
prints s  train test
2 3 0 1
1 3 0 2
1 2 0 3
0 3 1 2
0 2 1 3
0 1 2 3
```
Random permutations crossvalidation aka Shuffle Split
ShuffleSplit
TheShuffleSplit iterator will generate a user defined number of independent train test dataset splits Samples are first shuffled and then split into a pair of train and test sets
It is possible to control the randomness for reproducibility of the results by explicitly seeding the randomstate pseudo random number generator
Here is a usage example

```
 from sklearnmodelselection import ShuffleSplit
X  nparange10
ss  ShuffleSplitnsplits5 testsize025
 randomstate0
 for trainindex testindex insssplitX
 prints s  trainindex testindex
9 1 6 7 3 0 5 2 8 4
2 9 8 0 6 7 4 3 5 1
4 5 1 0 6 9 7 2 3 8
2 7 5 8 0 3 4 6 1 9
4 1 0 6 8 9 3 5 2 7
```
Here is a visualization of the crossvalidation behavior Note that ShuffleSplit is not affected by classes or groups

ShuffleSplit is thus a good alternative to KFold cross validation that allows a finer control on the number of iterations and the proportion of samples on each side of the train test split

Crossvalidation iterators with stratification based on class labels

Some classification problems can exhibit a large imbalance in the distribution of the target classes for instance there could be several times more negative samples than positive samples In such cases it is recommended to use stratified sampling as implemented in StratifiedKFold andStratifiedShuffleSplit to ensure that relative class frequencies is approximately preserved in each train and validation fold

Stratified kfold

StratifiedKFold is a variation of kfold which returns stratified folds each set contains approximately the same percentage of samples of each target class as the complete set

Example of stratified 3fold crossvalidation on a dataset with 10 samples from two slightly unbalanced classes
```
 from sklearnmodelselection import StratifiedKFold
X  npones10
y  0 0 0 0 1 1 1 1 1 1
skf  StratifiedKFoldnsplits3
 for train test inskfsplitX y
```

prints s train test
2 3 6 7 8 9 0 1 4 5
0 1 3 4 5 8 9 2 6 7
0 1 2 4 5 6 7 3 8 9
Here is a visualization of the crossvalidation behavior
RepeatedStratifiedKFold can be used to repeat Stratified KFold n times with different randomization in each repetition
Stratified Shuffle Split
StratifiedShuffleSplit is a variation of ShuffleSplit which returns stratified splits iewhich creates splits by preserving the same percentage for each target class as in the complete set
Here is a visualization of the crossvalidation behavior
Crossvalidation iterators for grouped data
The iid assumption is broken if the underlying generative process yield groups of dependent samples

Such a grouping of data is domain specific An example would be when there is medical data collected from multiple patients with multiple samples taken from each patient And such data is likely to be dependent on the individual group In our example the patient id for each sample will be its group identifier
In this case we would like to know if a model trained on a particular set of groups generalizes well to the unseen groups To measure this we need to ensure that all the samples in the validation fold come from groups that are not represented at all in the paired training fold
The following crossvalidation splitters can be used to do that The grouping identifier for the samples is specified via thegroups parameter
Group kfold
GroupKFold is a variation of kfold which ensures that the same group is not represented in both testing and training sets For example if the data is obtained from different subjects with several samples persubject and if the model is flexible enough to learn from highly person specific features it could fail to generalize to new subjects GroupKFold makes it possible to detect this kind of overfitting situations
Imagine you have three subjects each with an associated number from 1 to 3
```
 from sklearnmodelselection import GroupKFold
X  01 02 22 24 23 455 58 88 9 10
y  a b b b c c c d d d
groups  1 1 1 2 2 2 3 3 3 3
gkf  GroupKFoldnsplits3
 for train test ingkfsplitX y groupsgroups
 prints s  train test
0 1 2 3 4 5 6 7 8 9
0 1 2 6 7 8 9 3 4 5
3 4 5 6 7 8 9 0 1 2
```
Each subject is in a different testing fold and the same subject is never in both testing and training Notice that the folds do not have exactly the same size due to the imbalance in the data
Here is a visualization of the crossvalidation behavior

Leave One Group Out
LeaveOneGroupOut is a crossvalidation scheme which holds out the samples according to a thirdparty provided array of integer groups This group information can be used to encode arbitrary domain specific predefined cross validation folds
Each training set is thus constituted by all the samples except the ones related to a specific group
For example in the cases of multiple experiments LeaveOneGroupOut can be used to create a crossvalidation based on the different experiments we create a training set using the samples of all the experiments except one
```
 from sklearnmodelselection import LeaveOneGroupOut
X  1 5 10 50 60 70 80
y  0 1 1 2 2 2 2
groups  1 1 2 2 3 3 3
logo  LeaveOneGroupOut
 for train test inlogosplitX y groupsgroups
 prints s  train test
2 3 4 5 6 0 1
0 1 4 5 6 2 3
0 1 2 3 4 5 6
```
Another common application is to use time information for instance the groups could be the year of collection of the samples and thus allow for crossvalidation against timebased splits
Leave P Groups Out
LeavePGroupsOut is similar as LeaveOneGroupOut but removes samples related to groups for each train ingtest set
Example of Leave2Group Out
```
 from sklearnmodelselection import LeavePGroupsOut
X  nparange6
y  1 1 1 2 2 2
groups  1 1 2 2 3 3
lpgo  LeavePGroupsOutngroups2
 for train test inlpgosplitX y groupsgroups
 prints s  train test
4 5 0 1 2 3
2 3 0 1 4 5
0 1 2 3 4 5
```
Group Shuffle Split
TheGroupShuffleSplit iterator behaves as a combination of ShuffleSplit andLeavePGroupsOut and generates a sequence of randomized partitions in which a subset of groups are held out for each split
Here is a usage example
```
 from sklearnmodelselection import GroupShuffleSplit
X  01 02 22 24 23 455 58 0001
y  a b b b c c c a
```

scikitlearn user guide Release 0213
groups 1 1 2 2 3 3 4 4
gss GroupShuffleSplitnsplits4 testsize05 randomstate0
 for train test ingsssplitX y groupsgroups
 prints s train test

0 1 2 3 4 5 6 7
2 3 6 7 0 1 4 5
2 3 4 5 0 1 6 7
4 5 6 7 0 1 2 3
Here is a visualization of the crossvalidation behavior
This class is useful when the behavior of LeavePGroupsOut is desired but the number of groups is large enough
that generating all possible partitions with groups withheld would be prohibitively expensive In such a sce
narioGroupShuffleSplit provides a random sample with replacement of the train test splits generated by
LeavePGroupsOut
Predefined FoldSplits ValidationSets
For some datasets a predefined split of the data into training and validation fold or into several crossvalidation folds
already exists Using PredefinedSplit it is possible to use these folds eg when searching for hyperparameters
For example when using a validation set set the testfold to 0 for all samples that are part of the validation set
and to 1 for all other samples
Cross validation of time series data
Time series data is characterised by the correlation between observations that are near in time autocorrelation How
ever classical crossvalidation techniques such as KFold andShuffleSplit assume the samples are independent
and identically distributed and would result in unreasonable correlation between training and testing instances yield
ing poor estimates of generalisation error on time series data Therefore it is very important to evaluate our model
for time series data on the “future” observations least like those that are used to train the model To achieve this one
solution is provided by TimeSeriesSplit

Time Series Split
TimeSeriesSplit is a variation of kfold which returns first folds as train set and the 1 th fold as test set
Note that unlike standard crossvalidation methods successive training sets are supersets of those that come before
them Also it adds all surplus data to the first training partition which is always used to train the model
This class can be used to crossvalidate time series data samples that are observed at fixed time intervals
Example of 3split time series crossvalidation on a dataset with 6 samples
```
 from sklearnmodelselection import TimeSeriesSplit
X  nparray1 2 3 4 1 2 3 4 1 2 3 4
y  nparray1 2 3 4 5 6
tscv  TimeSeriesSplitnsplits3
printtscv
TimeSeriesSplitmaxtrainsizeNone nsplits3
 for train test intscvsplitX
 prints s  train test
0 1 2 3
0 1 2 3 4
0 1 2 3 4 5
```
Here is a visualization of the crossvalidation behavior
A note on shuffling
If the data ordering is not arbitrary eg samples with the same class label are contiguous shuffling it first may
be essential to get a meaningful cross validation result However the opposite may be true if the samples are not
independently and identically distributed For example if samples correspond to news articles and are ordered by
their time of publication then shuffling the data will likely lead to a model that is overfit and an inflated validation
score it will be tested on samples that are artificially similar close in time to training samples
Some cross validation iterators such as KFold have an inbuilt option to shuffle the data indices before splitting them
Note that
• This consumes less memory than shuffling the data directly
• By default no shuffling occurs including for the stratified K fold cross validation performed by specifying
cvsomeinteger tocrossvalscore grid search etc Keep in mind that traintestsplit
still returns a random split

• Therandomstate parameter defaults to None meaning that the shuffling will be different every time KFold shuffleTrue is iterated However GridSearchCV will use the same shuffling for each set of parameters validated by a single call to its fit method
• To get identical results for each split set randomstate to an integer
Cross validation and model selection
Cross validation iterators can also be used to directly perform model selection using Grid Search for the optimal hyperparameters of the model This is the topic of the next section Tuning the hyperparameters of an estimator
332 Tuning the hyperparameters of an estimator
Hyperparameters are parameters that are not directly learnt within estimators In scikitlearn they are passed as arguments to the constructor of the estimator classes Typical examples include Ckernel andgamma for Support Vector Classifier alpha for Lasso etc
It is possible and recommended to search the hyperparameter space for the best cross validation score
Any parameter provided when constructing an estimator may be optimized in this manner Specifically to find the names and current values for all parameters for a given estimator use
estimatorgetparams
A search consists of
• an estimator regressor or classifier such as sklearnsvmSVC
• a parameter space
• a method for searching or sampling candidates
• a crossvalidation scheme and
• ascore function
Some models allow for specialized efficient parameter search strategies outlined below Two generic approaches to sampling search candidates are provided in scikitlearn for given values GridSearchCV exhaustively considers all parameter combinations while RandomizedSearchCV can sample a given number of candidates from a parameter space with a specified distribution After describing these tools we detail best practice applicable to both approaches
Note that it is common that a small subset of those parameters can have a large impact on the predictive or computation performance of the model while others can be left to their default values It is recommended to read the docstring of the estimator class to get a finer understanding of their expected behavior possibly by reading the enclosed reference to the literature
Exhaustive Grid Search
The grid search provided by GridSearchCV exhaustively generates candidates from a grid of parameter values specified with the paramgrid parameter For instance the following paramgrid
paramgrid
C 1 10 100 1000 kernel linear
C 1 10 100 1000 gamma 0001 00001 kernel rbf

specifies that two grids should be explored one with a linear kernel and C values in 1 10 100 1000 and the second one with an RBF kernel and the crossproduct of C values ranging in 1 10 100 1000 and gamma values in 0001 00001

TheGridSearchCV instance implements the usual estimator API when “fitting” it on a dataset all the possible combinations of parameter values are evaluated and the best combination is retained

Examples

• See Parameter estimation using grid search with crossvalidation for an example of Grid Search computation on the digits dataset

• See Sample pipeline for text feature extraction and evaluation for an example of Grid Search coupling pa rameters from a text documents feature extractor ngram count vectorizer and TFIDF transformer with a classifier here a linear SVM trained with SGD with either elastic net or L2 penalty using a pipeline Pipeline instance

• See Nested versus nonnested crossvalidation for an example of Grid Search within a cross validation loop on the iris dataset This is the best practice for evaluating the performance of a model with grid search

• See Demonstration of multimetric evaluation on crossvalscore and GridSearchCV for an example of GridSearchCV being used to evaluate multiple metrics simultaneously

• See Balance model complexity and crossvalidated score for an example of using refitcallable in terface inGridSearchCV The example shows how this interface adds certain amount of flexibility in identifying the “best” estimator This interface can also be used in multiple metrics evaluation

Randomized Parameter Optimization

While using a grid of parameter settings is currently the most widely used method for parameter optimization other search methods have more favourable properties RandomizedSearchCV implements a randomized search over parameters where each setting is sampled from a distribution over possible parameter values This has two main benefits over an exhaustive search

• A budget can be chosen independent of the number of parameters and possible values

• Adding parameters that do not influence the performance does not decrease efficiency

Specifying how parameters should be sampled is done using a dictionary very similar to specifying parameters for GridSearchCV Additionally a computation budget being the number of sampled candidates or sampling itera tions is specified using the niter parameter For each parameter either a distribution over possible values or a list of discrete choices which will be sampled uniformly can be specified

C scipystatsexponscale100 gamma scipystatsexponscale1
kernel rbf classweightbalanced None

This example uses the scipystats module which contains many useful distributions for sampling parameters such asexpon gamma uniform orrandint In principle any function can be passed that provides a rvs random variate sample method to sample a value A call to the rvs function should provide independent random samples from possible parameter values on consecutive calls

Warning The distributions in scipystats prior to version scipy 016 do not allow specifying a random state Instead they use the global numpy random state that can be seeded via nprandom seed or set using nprandomsetstate However beginning scikitlearn 018 the sklearn

modelselection module sets the random state provided by the user if scipy 016 is also
available
For continuous parameters such as Cabove it is important to specify a continuous distribution to take full advantage
of the randomization This way increasing niter will always lead to a finer search
Examples
•Comparing randomized search and grid search for hyperparameter estimation compares the usage and effi
ciency of randomized search and grid search

Tips for parameter search
Specifying an objective metric
By default parameter search uses the score function of the estimator to evaluate a parameter setting These are
thesklearnmetricsaccuracyscore for classification and sklearnmetricsr2score for regres
sion For some applications other scoring functions are better suited for example in unbalanced classification the
accuracy score is often uninformative An alternative scoring function can be specified via the scoring parameter
toGridSearchCV RandomizedSearchCV and many of the specialized crossvalidation tools described below
SeeThe scoring parameter defining model evaluation rules for more details
Specifying multiple metrics for evaluation
GridSearchCV andRandomizedSearchCV allow specifying multiple metrics for the scoring parameter
Multimetric scoring can either be specified as a list of strings of predefined scores names or a dict mapping the scorer
name to the scorer function andor the predefined scorer names See Using multiple metric evaluation for more
details
When specifying multiple metrics the refit parameter must be set to the metric string for which the
bestparams will be found and used to build the bestestimator on the whole dataset If the search
should not be refit set refitFalse Leaving refit to the default value None will result in an error when using
multiple metrics
SeeDemonstration of multimetric evaluation on crossvalscore and GridSearchCV for an example usage
Composite estimators and parameter spaces
Pipeline chaining estimators describes building composite estimators whose parameter space can be searched with
these tools

Model selection development and evaluation
Model selection by evaluating various parameter settings can be seen as a way to use the labeled data to “train” the parameters of the grid
When evaluating the resulting model it is important to do it on heldout samples that were not seen during the grid search process it is recommended to split the data into a development set to be fed to the GridSearchCV instance and an evaluation set to compute performance metrics
This can be done by using the traintestsplit utility function
Parallelism
GridSearchCV andRandomizedSearchCV evaluate each parameter setting independently Computations can be run in parallel if your OS supports it by using the keyword njobs1 See function signature for more details
Robustness to failure
Some parameter settings may result in a failure to fit one or more folds of the data By default this will cause the entire search to fail even if some parameter settings could be fully evaluated Setting errorscore0 ornp NaN will make the procedure robust to such failure issuing a warning and setting the score for that fold to 0 or NaN but completing the search
Alternatives to brute force parameter search
Model specific crossvalidation
Some models can fit data for a range of values of some parameter almost as efficiently as fitting the estimator for a single value of the parameter This feature can be leveraged to perform a more efficient crossvalidation used for model selection of this parameter
The most common parameter amenable to this strategy is the parameter encoding the strength of the regularizer In this case we say that we compute the regularization path of the estimator
Here is the list of such models
linearmodelElasticNetCV l1ratio eps Elastic Net model with iterative fitting along a regulariza tion path
linearmodelLarsCV fitintercept Crossvalidated Least Angle Regression model
linearmodelLassoCV eps nalphas Lasso linear model with iterative fitting along a regulariza tion path
linearmodelLassoLarsCV fitintercept Crossvalidated Lasso using the LARS algorithm

Read more in the User Guide
Parameters
l1ratio float or array of floats optional float between 0 and 1 passed to ElasticNet scal
ing between l1 and l2 penalties For l1ratio 0 the penalty is an L2 penalty For
l1ratio 1 it is an L1 penalty For 0 l1ratio 1 the penalty is a com
bination of L1 and L2 This parameter can be a list in which case the different values are
tested by crossvalidation and the one giving the best prediction score is used Note that a
good choice of list of values for l1ratio is often to put more values close to 1 ie Lasso
and less close to 0 ie Ridge as in 1 5 7 9 95 99 1
eps float optional Length of the path eps1e3 means thatalphamin alphamax
1e3
nalphas int optional Number of alphas along the regularization path used for each l1ratio
alphas numpy array optional List of alphas where to compute the models If None alphas are
set automatically
fitintercept boolean whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
precompute True False 'auto' arraylike Whether to use a precomputed Gram matrix to
speed up calculations If set to auto let us decide The Gram matrix can also be passed
as argument
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation

• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
copyX boolean optional default True If True X will be copied else it may be overwritten
verbose bool or integer Amount of verbosity
njobs int or None optional defaultNone Number of CPUs to use during the cross valida
tionNone means 1 unless in a joblibparallelbackend context1means using
all processors See Glossary for more details
positive bool optional When set to True forces the coefficients to be positive
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection ‘random’
selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
alpha float The amount of penalization chosen by cross validation
l1ratio float The compromise between l1 and l2 penalization chosen by cross validation
coef array shape nfeatures ntargets nfeatures Parameter vector w in the cost func
tion formula
intercept float array shape ntargets nfeatures Independent term in the decision func
tion
msepath array shape nl1ratio nalpha nfolds Mean square error for the test set on
each fold varying l1ratio and alpha
alphas numpy array shape nalphas or nl1ratio nalphas The grid of alphas used for
fitting for each l1ratio
niter int number of iterations run by the coordinate descent solver to reach the specified
tolerance for the optimal alpha
See also
enetpath
ElasticNet
Notes
For an example see exampleslinearmodelplotlassomodelselectionpy

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortrancontiguous numpy array
The parameter l1ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet More specifically the optimization objective is
1 2nsamples y Xw22
 alpha l1ratio w1
 05alpha1 l1ratio w22
If you are interested in controlling the L1 and L2 penalty separately keep in mind that this is equivalent to
aL1 bL2
for
alpha a b andl1ratio a a b

predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns

Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
sklearnlinearmodel LarsCV
classsklearnlinearmodel LarsCVfitinterceptTrue verboseFalse maxiter500
normalizeTrue precompute’auto’

Parameters
fitintercept boolean whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered

verbose boolean or integer optional Sets the verbosity amount
maxiter integer optional Maximum number of iterations to perform
normalize boolean optional default True This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized before regression by sub tracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before calling fit on an estimator withnormalizeFalse
precompute True False 'auto' arraylike Whether to use a precomputed Gram matrix to speed up calculations If set to auto let us decide The Gram matrix cannot be passed as argument since we will use only subsets of X
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
maxnalphas integer optional The maximum number of points on the path used to compute the residuals in the crossvalidation
njobs int or None optional defaultNone Number of CPUs to use during the cross valida tionNone means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
eps float optional The machineprecision regularization in the computation of the Cholesky diagonal factors Increase this for very illconditioned systems
copyX boolean optional default True If True X will be copied else it may be overwritten
positive boolean defaultFalse Restrict coefficients to be 0 Be aware that you might want to remove fitintercept which is set True by default
Deprecated since version 020 The option is broken and deprecated It will be removed in v022
Attributes
coef array shape nfeatures parameter vector w in the formulation formula
intercept float independent term in decision function
coefpath array shape nfeatures nalphas the varying values of the coefficients along the path
alpha float the estimated regularization parameter alpha
alphas array shape nalphas the different values of alpha along the path
cvalphas array shape ncvalphas all the values of alpha along the path for the different folds

msepath array shape nfolds ncvalphas the mean square error on leftout for each fold

predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values

scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnlinearmodelLassoCV
•Crossvalidation on diabetes Dataset Exercise
•Feature selection using SelectFromModel and LassoCV
•Lasso model selection CrossValidation AIC BIC
sklearnlinearmodel LassoLarsCV
classsklearnlinearmodel LassoLarsCV fitinterceptTrue verboseFalse maxiter500
normalizeTrue precompute’auto’
cv’warn’ maxnalphas1000 njobsNone

tiveFalse
Crossvalidated Lasso using the LARS algorithm

See glossary entry for crossvalidation estimator
The optimization objective for Lasso is
1 2 nsamples y Xw22 alpha w1
Read more in the User Guide
Parameters
fitintercept boolean whether to calculate the intercept for this model If set to false no intercept will be used in calculations eg data is expected to be already centered
verbose boolean or integer optional Sets the verbosity amount
maxiter integer optional Maximum number of iterations to perform
normalize boolean optional default True This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized before regression by sub tracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before calling fit on an estimator withnormalizeFalse
precompute True False 'auto' Whether to use a precomputed Gram matrix to speed up calculations If set to auto let us decide The Gram matrix cannot be passed as argument since we will use only subsets of X
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
maxnalphas integer optional The maximum number of points on the path used to compute the residuals in the crossvalidation
njobs int or None optional defaultNone Number of CPUs to use during the cross valida tionNone means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
eps float optional The machineprecision regularization in the computation of the Cholesky diagonal factors Increase this for very illconditioned systems
copyX boolean optional default True If True X will be copied else it may be overwritten
positive boolean defaultFalse Restrict coefficients to be 0 Be aware that you might want to remove fitintercept which is set True by default Under the positive restriction the model coefficients do not converge to the ordinaryleastsquares solution for small values of alpha Only coefficients up to the smallest alpha value alphasalphas 0 min when fitpathTrue reached by the stepwise LarsLasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator As a consequence

using LassoLarsCV only makes sense for problems where a sparse solution is expected
andor reached
Attributes
coef array shape nfeatures parameter vector w in the formulation formula
intercept float independent term in decision function
coefpath array shape nfeatures nalphas the varying values of the coefficients along the
path
alpha float the estimated regularization parameter alpha
alphas array shape nalphas the different values of alpha along the path
cvalphas array shape ncvalphas all the values of alpha along the path for the different
folds
msepath array shape nfolds ncvalphas the mean square error on leftout for each fold
along the path alpha values given by cvalphas
niter arraylike or int the number of iterations run by Lars with the optimal alpha
See also
larspath LassoLars LarsCV LassoCV
Notes
The object solves the same problem as the LassoCV object However unlike the LassoCV it find the relevant
alphas values by itself In general because of this property it will be more stable However it is more fragile to
heavily multicollinear datasets
It is more efficient than the LassoCV if only a small number of features are selected compared to the total
number for instance if there are very few samples compared to the number of features

Examples using sklearnlinearmodelLassoLarsCV
•Lasso model selection CrossValidation AIC BIC
sklearnlinearmodel LogisticRegressionCV
classsklearnlinearmodel LogisticRegressionCV Cs10 fitinterceptTrue cv’warn’
dualFalse penalty’l2’ scor
ingNone solver’lbfgs’ tol00001
maxiter100 classweightNone
njobsNone verbose0 refitTrue in
terceptscaling10 multiclass’warn’
randomstateNone l1ratiosNone
Logistic Regression CV aka logit MaxEnt classifier
See glossary entry for crossvalidation estimator
This class implements logistic regression using liblinear newtoncg sag of lbfgs optimizer The newtoncg sag
and lbfgs solvers support only L2 regularization with primal formulation The liblinear solver supports both L1
and L2 regularization with a dual formulation only for the L2 penalty ElasticNet penalty is only supported by
the saga solver
For the grid of Csvalues and l1ratios values the best hyperparameter is selected by the crossvalidator
StratifiedKFold but it can be changed using the cvparameter The ‘newtoncg’ ‘sag’ ‘saga’ and ‘lbfgs’
solvers can warmstart the coefficients see Glossary
Read more in the User Guide
Parameters
Cslist of floats or int optional default10 Each of the values in Cs describes the inverse of
regularization strength If Cs is as an int then a grid of Cs values are chosen in a logarith
mic scale between 1e4 and 1e4 Like in support vector machines smaller values specify
stronger regularization
fitintercept bool optional defaultTrue Specifies if a constant aka bias or intercept
should be added to the decision function

cvint or crossvalidation generator optional defaultNone The default crossvalidation gen
erator used is Stratified KFolds If an integer is provided then it is the number of folds
used See the module sklearnmodelselection module for the list of possible
crossvalidation objects
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
dual bool optional defaultFalse Dual or primal formulation Dual formulation is only
implemented for l2 penalty with liblinear solver Prefer dualFalse when nsamples
nfeatures
penalty str ‘l1’ ‘l2’ or ‘elasticnet’ optional default’l2’ Used to specify the norm used
in the penalization The ‘newtoncg’ ‘sag’ and ‘lbfgs’ solvers support only l2 penalties
‘elasticnet’ is only supported by the ‘saga’ solver
scoring string callable or None optional defaultNone A string see model evaluation doc
umentation or a scorer callable object function with signature scorerestimator
X y For a list of scoring functions that can be used look at sklearnmetrics The
default scoring option used is ‘accuracy’
solver str ‘newtoncg’ ‘lbfgs’ ‘liblinear’ ‘sag’ ‘saga’ optional default’lbfgs’ Algo
rithm to use in the optimization problem
• For small datasets ‘liblinear’ is a good choice whereas ‘sag’ and ‘saga’ are faster for
large ones
• For multiclass problems only ‘newtoncg’ ‘sag’ ‘saga’ and ‘lbfgs’ handle multinomial
loss ‘liblinear’ is limited to oneversusrest schemes
• ‘newtoncg’ ‘lbfgs’ and ‘sag’ only handle L2 penalty whereas ‘liblinear’ and ‘saga’
handle L1 penalty
• ‘liblinear’ might be slower in LogisticRegressionCV because it does not handle warm
starting
Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approxi
mately the same scale You can preprocess the data with a scaler from sklearnpreprocessing
New in version 017 Stochastic Average Gradient descent solver
New in version 019 SAGA solver
tolfloat optional default1e4 Tolerance for stopping criteria
maxiter int optional default100 Maximum number of iterations of the optimization al
gorithm
classweight dict or ‘balanced’ optional defaultNone Weights associated with classes in
the formclasslabel weight If not given all classes are supposed to have
weight one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified
New in version 017 classweight ‘balanced’

njobs int or None optional defaultNone Number of CPU cores used during the cross validation loop None means 1 unless in a joblibparallelbackend context1 means using all processors See Glossary for more details
verbose int optional default0 For the ‘liblinear’ ‘sag’ and ‘lbfgs’ solvers set verbose to any positive number for verbosity
refit bool optional defaultTrue If set to True the scores are averaged across all folds and the coefs and the C that corresponds to the best score is taken and a final refit is done using these parameters Otherwise the coefs intercepts and C that correspond to the best scores across folds are averaged
interceptscaling float optional default1 Useful only when the solver ‘liblinear’ is used and selffitintercept is set to True In this case x becomes x selfinterceptscaling ie a “synthetic” feature with constant value equal to interceptscaling is ap pended to the instance vector The intercept becomes interceptscaling syntheticfeatureweight
Note the synthetic feature weight is subject to l1l2 regularization as all other features To lessen the effect of regularization on synthetic feature weight and therefore on the intercept interceptscaling has to be increased
multiclass str ‘ovr’ ‘multinomial’ ‘auto’ optional default’ovr’ If the option chosen is ‘ovr’ then a binary problem is fit for each label For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution even when the data is binary ‘multinomial’ is unavailable when solver’liblinear’ ‘auto’ selects ‘ovr’ if the data is binary or if solver’liblinear’ and otherwise selects ‘multinomial’
New in version 018 Stochastic Average Gradient descent solver for ‘multinomial’ case
Changed in version 020 Default will change from ‘ovr’ to ‘auto’ in 022
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
l1ratios list of float or None optional defaultNone The list of ElasticNet mixing parame ter with0 l1ratio 1 Only used if penaltyelasticnet A value of 0 is equivalent to using penaltyl2 while 1 is equivalent to using penaltyl1 For0 l1ratio 1 the penalty is a combination of L1 and L2
Attributes
classes array shape nclasses A list of class labels known to the classifier
coef array shape 1 nfeatures or nclasses nfeatures Coefficient of the features in the decision function
coef is of shape 1 nfeatures when the given problem is binary
intercept array shape 1 or nclasses Intercept aka bias added to the decision func tion
Iffitintercept is set to False the intercept is set to zero intercept is of shape1 when the problem is binary
Cs array shape ncs Array of C ie inverse of regularization parameter values used for crossvalidation
l1ratios array shape nl1ratios Array of l1ratios used for crossvalidation If no l1ratio is used ie penalty is not ‘elasticnet’ this is set to None

coefspaths array shape nfolds ncs nfeatures or nfolds ncs nfeatures 1 dict
with classes as the keys and the path of coefficients obtained during crossvalidating
across each fold and then across each Cs after doing an OvR for the correspond
ing class as values If the ‘multiclass’ option is set to ‘multinomial’ then the co
efspaths are the coefficients corresponding to each class Each dict value has shape
nfolds ncs nfeatures ornfolds ncs nfeatures 1
depending on whether the intercept is fit or not If penaltyelasticnet the shape
isnfolds ncs nl1ratios nfeatures ornfolds ncs
nl1ratios nfeatures 1
scores dict dict with classes as the keys and the values as the grid of scores obtained dur
ing crossvalidating each fold after doing an OvR for the corresponding class If the
‘multiclass’ option given is ‘multinomial’ then the same scores are repeated across all
classes since this is the multinomial class Each dict value has shape nfolds ncs
ornfolds ncs nl1ratios ifpenaltyelasticnet
Carray shape nclasses or nclasses 1 Array of C that maps to the best scores across
every class If refit is set to False then for each class the best C is the average of the C’s that
correspond to the best scores for each fold Cis of shapenclasses when the problem is
binary
l1ratio array shape nclasses or nclasses 1 Array of l1ratio that maps to the best
scores across every class If refit is set to False then for each class the best l1ratio is the
average of the l1ratio’s that correspond to the best scores for each fold l1ratio is of
shapenclasses when the problem is binary
niter array shape nclasses nfolds ncs or 1 nfolds ncs Actual number of itera
tions for all classes folds and Cs In the binary or multinomial cases the first dimension
is equal to 1 If penaltyelasticnet the shape is nclasses nfolds
ncs nl1ratios or1 nfolds ncs nl1ratios

solver'lbfgs' tol00001 maxiter100 classweightNone njobsNone ver
bose0 refitTrue interceptscaling10 multiclass'warn' randomstateNone
l1ratiosNone
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
densifyself
Convert coefficient matrix to dense array format
Converts the coef member back to a numpyndarray This is the default format of coef and is
required for fitting so calling this method is only required on models that have previously been sparsified
otherwise it is a noop
Returns
self estimator
fitselfXysampleweightNone
Fit the model according to the given training data
Parameters
Xarraylike sparse matrix shape nsamples nfeatures Training vector where
nsamples is the number of samples and nfeatures is the number of features
yarraylike shape nsamples Target vector relative to X
sampleweight arraylike shape nsamples optional Array of weights that are assigned
to individual samples If not provided then each sample is given unit weight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters

deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Predicted class label per sample
predictlogproba selfX
Log of probability estimates
The returned estimates for all classes are ordered by the label of classes
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tarraylike shape nsamples nclasses Returns the logprobability of the sample for
each class in the model where classes are ordered as they are in selfclasses
predictproba selfX
Probability estimates
The returned estimates for all classes are ordered by the label of classes
For a multiclass problem if multiclass is set to be “multinomial” the softmax function is used to find
the predicted probability of each class Else use a onevsrest approach ie calculate the probability of
each class assuming it to be positive using the logistic function and normalize these values across all the
classes
Parameters
Xarraylike shape nsamples nfeatures
Returns
Tarraylike shape nsamples nclasses Returns the probability of the sample for each
class in the model where classes are ordered as they are in selfclasses
scoreselfXysampleweightNone
Returns the score using the scoring option on the given test data and labels
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Score of selfpredictX wrt y

scikitlearn user guide Release 0213
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self
sparsify self
Convert coefficient matrix to sparse format
Converts the coef member to a scipysparse matrix which for L1regularized models can be much more memory and storageefficient than the usual numpyndarray representation
Theintercept member is not converted
Returns
self estimator
Notes
For nonsparse models ie when there are not many zeros in coef this may actually increase memory usage so use this method with care A rule of thumb is that the number of zero elements which can be computed with coef 0sum must be more than 50 for this to provide significant benefits
After calling this method further fitting with the partialfit method if any will not work until you call densify
sklearnlinearmodel MultiTaskElasticNetCV
classsklearnlinearmodel MultiTaskElasticNetCV l1ratio05 eps0001 nalphas100

The optimization objective for MultiTaskElasticNet is
1 2 nsamples Y XWFro2
 alpha l1ratio W21
 05alpha1 l1ratio WFro2
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters

l1ratio float or array of floats The ElasticNet mixing parameter with 0 l1ratio 1 For l1ratio 1 the penalty is an L1L2 penalty For l1ratio 0 it is an L2 penalty For 0 l1ratio 1 the penalty is a combination of L1L2 and L2 This parameter can be a list in which case the different values are tested by crossvalidation and the one giving the best prediction score is used Note that a good choice of list of values for l1ratio is often to put more values close to 1 ie Lasso and less close to 0 ie Ridge as in 1 5 7 9 95 99 1
eps float optional Length of the path eps1e3 means thatalphamin alphamax 1e3
nalphas int optional Number of alphas along the regularization path
alphas arraylike optional List of alphas where to compute the models If not provided set automatically
fitintercept boolean whether to calculate the intercept for this model If set to false no intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized be fore regression by subtracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before callingfit on an estimator with normalizeFalse
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the optimization code checks the dual gap for optimality and continues until it is smaller than tol
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in v022
copyX boolean optional default True If True X will be copied else it may be overwritten
verbose bool or integer Amount of verbosity
njobs int or None optional defaultNone Number of CPUs to use during the cross vali dation Note that this is used only if multiple values for l1ratio are given None means 1 unless in a joblibparallelbackend context1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional default None The seed of the pseudo random number generator that selects a random feature to update If int ran domstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom Used when selection ‘random’

selection str default ‘cyclic’ If set to ‘random’ a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to ‘random’ often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
intercept array shape ntasks Independent term in decision function
coef array shape ntasks nfeatures Parameter vector W in the cost function formula
Note thatcoef stores the transpose of WWT
alpha float The amount of penalization chosen by cross validation
msepath array shape nalphas nfolds or nl1ratio nalphas nfolds mean square
error for the test set on each fold varying alpha
alphas numpy array shape nalphas or nl1ratio nalphas The grid of alphas used for
fitting for each l1ratio
l1ratio float best l1ratio obtained by crossvalidation
niter int number of iterations run by the coordinate descent solver to reach the specified
tolerance for the optimal alpha

Parameters
Xarraylike shape nsamples nfeatures Training data Pass directly as Fortran
contiguous data to avoid unnecessary memory duplication If yis monooutput then X
can be sparse
yndarray shape nsamples or nsamples noutputs Target values
l1ratio float optional float between 0 and 1 passed to elastic net scaling between l1 and
l2 penalties l1ratio1 corresponds to the Lasso
eps float Length of the path eps1e3 means that alphamin alphamax
1e3
nalphas int optional Number of alphas along the regularization path
alphas ndarray optional List of alphas where to compute the models If None alphas are
set automatically
precompute True False 'auto' arraylike Whether to use a precomputed Gram matrix
to speed up calculations If set to auto let us decide The Gram matrix can also be
passed as argument
Xyarraylike optional Xy npdotXT y that can be precomputed It is useful only
when the Gram matrix is precomputed
copyX boolean optional default True If True X will be copied else it may be over
written
coefinit array shape nfeatures None The initial values of the coefficients
verbose bool or integer Amount of verbosity
returnniter bool whether to return the number of iterations or not
positive bool default False If set to True forces coefficients to be positive Only allowed
whenyndim 1
checkinput bool default True Skip input validation checks including the Gram matrix
when provided assuming there are handled by the caller when checkinputFalse
params kwargs keyword arguments passed to the coordinate descent solver
Returns
alphas array shape nalphas The alphas along the path where models are computed
coefs array shape nfeatures nalphas or noutputs nfeatures nalphas Coefficients
along the path
dualgaps array shape nalphas The dual gaps at the end of the optimization for each
alpha
niters arraylike shape nalphas The number of iterations taken by the coordinate
descent optimizer to reach the specified tolerance for each alpha Is returned when
returnniter is set to True

predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object

Returns
self
sklearnlinearmodel MultiTaskLassoCV
classsklearnlinearmodel MultiTaskLassoCV eps0001 nalphas100 alphasNone
fitinterceptTrue normalizeFalse
maxiter1000 tol00001 copyXTrue
cv'warn' verboseFalse njobsNone
randomstateNone selection'cyclic'
Multitask Lasso model trained with L1L2 mixednorm as regularizer
See glossary entry for crossvalidation estimator
The optimization objective for MultiTaskLasso is
1 2 nsamples Y XWFro2 alpha W21
Where
W21 sumi sqrtsumj wij2
ie the sum of norm of each row
Read more in the User Guide
Parameters
eps float optional Length of the path eps1e3 means thatalphamin alphamax
 1e3
nalphas int optional Number of alphas along the regularization path
alphas arraylike optional List of alphas where to compute the models If not provided set
automatically
fitintercept boolean whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
maxiter int optional The maximum number of iterations
tolfloat optional The tolerance for the optimization if the updates are smaller than tol the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol
copyX boolean optional default True If True X will be copied else it may be overwritten
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter

• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
verbose bool or integer Amount of verbosity
njobs int or None optional defaultNone Number of CPUs to use during the cross vali
dation Note that this is used only if multiple values for l1ratio are given None means 1
unless in a joblibparallelbackend context1means using all processors See
Glossary for more details
randomstate int RandomState instance or None optional default None The seed of the
pseudo random number generator that selects a random feature to update If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom Used when selection 'random'
selection str default 'cyclic' If set to 'random' a random coefficient is updated every iteration
rather than looping over features sequentially by default This setting to 'random' often
leads to significantly faster convergence especially when tol is higher than 1e4
Attributes
intercept array shape ntasks Independent term in decision function
coef array shape ntasks nfeatures Parameter vector W in the cost function formula
Note thatcoef stores the transpose of WWT
alpha float The amount of penalization chosen by cross validation
msepath array shape nalphas nfolds mean square error for the test set on each fold
varying alpha
alphas numpy array shape nalphas The grid of alphas used for fitting
niter int number of iterations run by the coordinate descent solver to reach the specified
tolerance for the optimal alpha

predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns

Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage

normalizeTrue
maxiterNone cv‘warn’
njobsNone verboseFalse
Crossvalidated Orthogonal Matching Pursuit model OMP
See glossary entry for crossvalidation estimator
Read more in the User Guide
Parameters
copy bool optional Whether the design matrix X must be copied by the algorithm A false
value is only helpful if X is already Fortranordered otherwise a copy is made anyway

fitintercept boolean optional whether to calculate the intercept for this model If set to false
no intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default True This parameter is ignored when fitintercept
is set to False If True the regressors X will be normalized before regression by sub
tracting the mean and dividing by the l2norm If you wish to standardize please use
sklearnpreprocessingStandardScaler before calling fit on an estimator
withnormalizeFalse
maxiter integer optional Maximum numbers of iterations to perform therefore maximum
features to include 10 of nfeatures but at least 5 if available
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the default 3fold crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs KFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
Changed in version 020 cvdefault value if None will change from 3fold to 5fold in
v022
njobs int or None optional defaultNone Number of CPUs to use during the cross valida
tionNone means 1 unless in a joblibparallelbackend context1means using
all processors See Glossary for more details
verbose boolean or integer optional Sets the verbosity amount
Attributes
intercept float or array shape ntargets Independent term in decision function
coef array shape nfeatures or ntargets nfeatures Parameter vector w in the problem
formulation
nnonzerocoefs int Estimated number of nonzero coefficients giving the best mean
squared error over the crossvalidation folds
niter int or arraylike Number of active features across every target for the model refit with
the best hyperparameters got by crossvalidating across all folds

self
Examples using sklearnlinearmodelOrthogonalMatchingPursuitCV
•Orthogonal Matching Pursuit
sklearnlinearmodel RidgeCV
classsklearnlinearmodel RidgeCValphas01 10100 fitinterceptTrue normal
izeFalse scoringNone cvNone gcvmodeNone
storecvvaluesFalse
Ridge regression with builtin crossvalidation

See glossary entry for crossvalidation estimator
By default it performs Generalized CrossValidation which is a form of efficient LeaveOneOut cross validation
Read more in the User Guide
Parameters
alphas numpy array of shape nalphas Array of alpha values to try Regularization strength must be a positive float Regularization improves the conditioning of the problem and reduces the variance of the estimates Larger values specify stronger regularization Alpha corresponds to C1 in other linear models such as LogisticRegression or LinearSVC If using generalized crossvalidation alphas must be positive
fitintercept boolean Whether to calculate the intercept for this model If set to false no intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized before regression by subtracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before callingfit on an estimator with normalizeFalse
scoring string callable or None optional default None A string see model evaluation documentation or a scorer callable object function with signature scorerestimator X y If None the negative mean squared error if cv is ‘auto’ or None ie when using generalized crossvalidation and r2 score otherwise
cvint crossvalidation generator or an iterable optional Determines the crossvalidation splitting strategy Possible inputs for cv are
• None to use the efficient LeaveOneOut crossvalidation also known as Generalized CrossValidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices
For integerNone inputs if yis binary or multiclass sklearnmodelselection StratifiedKFold is used else sklearnmodelselectionKFold is used
Refer User Guide for the various crossvalidation strategies that can be used here
gcvmode None ‘auto’ ‘svd’ eigen’ optional Flag indicating which strategy to use when performing Generalized CrossValidation Options are
auto use svd ifnsamples nfeatures otherwise use eigen
svd force use of singular value decomposition of X when X is dense eigenvalue decomposition of XTX when X issparse
eigen force computation via eigendecomposition of XXT
The ‘auto’ mode is the default and is intended to pick the cheaper option of the two depending on the shape of the training data
storecvvalues boolean defaultFalse Flag indicating if the crossvalidation values corresponding to each alpha should be stored in the cvvalues attribute see below This flag is only compatible with cvNone ie using Generalized CrossValidation
Attributes

cvvalues array shape nsamples nalphas or shape nsamples ntargets nalphas
optional Crossvalidation values for each alpha if storecvvaluesTrue and
cvNone Afterfit has been called this attribute will contain the mean squared
errors by default or the values of the lossscorefunc function if provided in the
constructor
coef array shape nfeatures or ntargets nfeatures Weight vectors
intercept float array shape ntargets Independent term in decision function Set to 00
iffitintercept False
alpha float Estimated regularization parameter

float64 if necessary
yarraylike shape nsamples or nsamples ntargets Target values Will be cast to
X’s dtype if necessary
sampleweight float or arraylike of shape nsamples Sample weight
Returns

self object
Notes
When sampleweight is provided the selected hyperparameter may depend on whether we use generalized
crossvalidation cvNone or cv’auto’ or another form of crossvalidation because only generalized
crossvalidation takes the sample weights into account when computing the validation score
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

normalizeFalse scoringNone cvNone
classweightNone storecvvaluesFalse
Ridge classifier with builtin crossvalidation
See glossary entry for crossvalidation estimator
By default it performs Generalized CrossValidation which is a form of efficient LeaveOneOut cross
validation Currently only the nfeatures nsamples case is handled efficiently
Read more in the User Guide
Parameters
alphas numpy array of shape nalphas Array of alpha values to try Regularization strength
must be a positive float Regularization improves the conditioning of the problem and re
duces the variance of the estimates Larger values specify stronger regularization Alpha
corresponds to C1 in other linear models such as LogisticRegression or LinearSVC
fitintercept boolean Whether to calculate the intercept for this model If set to false no
intercept will be used in calculations eg data is expected to be already centered
normalize boolean optional default False This parameter is ignored when
fitintercept is set to False If True the regressors X will be normalized be
fore regression by subtracting the mean and dividing by the l2norm If you wish to
standardize please use sklearnpreprocessingStandardScaler before
callingfit on an estimator with normalizeFalse
scoring string callable or None optional default None A string see model evaluation doc
umentation or a scorer callable object function with signature scorerestimator
X y
cvint crossvalidation generator or an iterable optional Determines the crossvalidation split
ting strategy Possible inputs for cv are
• None to use the efficient LeaveOneOut crossvalidation
• integer to specify the number of folds
•CV splitter
• An iterable yielding train test splits as arrays of indices

Refer User Guide for the various crossvalidation strategies that can be used here
classweight dict or ‘balanced’ optional Weights associated with classes in the form
classlabel weight If not given all classes are supposed to have weight one
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
storecvvalues boolean defaultFalse Flag indicating if the crossvalidation values corre
sponding to each alpha should be stored in the cvvalues attribute see below This
flag is only compatible with cvNone ie using Generalized CrossValidation
Attributes
cvvalues array shape nsamples ntargets nalphas optional Crossvalidation values
for each alpha if storecvvaluesTrue andcvNone Afterfit has been
called this attribute will contain the mean squared errors by default or the values of the
lossscorefunc function if provided in the constructor
coef array shape 1 nfeatures or ntargets nfeatures Coefficient of the features in the
decision function
coef is of shape 1 nfeatures when the given problem is binary
intercept float array shape ntargets Independent term in decision function Set to 00
iffitintercept False
alpha float Estimated regularization parameter

Methods

scikitlearn user guide Release 0213
decisionfunction self X Predict confidence scores for samples
fitself X y sampleweight Fit the ridge classifier
getparams self deep Get parameters for this estimator
predict self X Predict class labels for samples in X
score self X y sampleweight Returns the mean accuracy on the given test data and
labels
setparams self params Set the parameters of this estimator
init selfalphas01 10100 fitinterceptTrue normalizeFalse scoringNone cvNone
classweightNone storecvvaluesFalse
decisionfunction selfX
Predict confidence scores for samples
The confidence score for a sample is the signed distance of that sample to the hyperplane
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
array shapensamples if nclasses 2 else nsamples nclasses Confidence
scores per sample class combination In the binary case confidence score for
selfclasses1 where 0 means this class would be predicted
fitselfXysampleweightNone
Fit the ridge classifier
Parameters
Xarraylike shape nsamples nfeatures Training vectors where nsamples is the num
ber of samples and nfeatures is the number of features When using GCV will be cast to
float64 if necessary
yarraylike shape nsamples Target values Will be cast to X's dtype if necessary
sampleweight float or numpy array of shape nsamples Sample weight
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class labels for samples in X
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns

Carray shape nsamples Predicted class label per sample
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Information Criterion
Some models can offer an informationtheoretic closedform formula of the optimal estimate of the regularization
parameter by computing a single regularization path instead of several when using crossvalidation
Here is the list of models benefiting from the Akaike Information Criterion AIC or the Bayesian Information Criterion
BIC for automated model selection
linearmodelLassoLarsIC criterion   Lasso model fit with Lars using BIC or AIC for model se
lection
sklearnlinearmodel LassoLarsIC
classsklearnlinearmodel LassoLarsIC criterion’aic’ fitinterceptTrue verboseFalse
normalizeTrue precompute’auto’ maxiter500
eps2220446049250313e16 copyXTrue posi
tiveFalse
Lasso model fit with Lars using BIC or AIC for model selection
The optimization objective for Lasso is
1 2 nsamples y Xw22 alpha w1
AIC is the Akaike information criterion and BIC is the Bayes Information criterion Such criteria are useful
to select the value of the regularization parameter by making a tradeoff between the goodness of fit and the
complexity of the model A good model should explain well the data while being simple
Read more in the User Guide

Parameters
criterion ‘bic’ ‘aic’ The type of criterion to use
fitintercept boolean whether to calculate the intercept for this model If set to false no intercept will be used in calculations eg data is expected to be already centered
verbose boolean or integer optional Sets the verbosity amount
normalize boolean optional default True This parameter is ignored when fitintercept is set to False If True the regressors X will be normalized before regression by subtracting the mean and dividing by the l2norm If you wish to standardize please use sklearnpreprocessingStandardScaler before calling fit on an estimator withnormalizeFalse
precompute True False ‘auto’ arraylike Whether to use a precomputed Gram matrix to speed up calculations If set to auto let us decide The Gram matrix can also be passed as argument
maxiter integer optional Maximum number of iterations to perform Can be used for early stopping
eps float optional The machineprecision regularization in the computation of the Cholesky diagonal factors Increase this for very illconditioned systems Unlike the tol parameter in some iterative optimizationbased algorithms this parameter does not control the tolerance of the optimization
copyX boolean optional default True If True X will be copied else it may be overwritten
positive boolean defaultFalse Restrict coefficients to be 0 Be aware that you might want to remove fitintercept which is set True by default Under the positive restriction the model coefficients do not converge to the ordinaryleastsquares solution for small values of alpha Only coefficients up to the smallest alpha value alphasalphas 0 min when fitpathTrue reached by the stepwise LarsLasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator As a consequence using LassoLarsIC only makes sense for problems where a sparse solution is expected andor reached
Attributes
coef array shape nfeatures parameter vector w in the formulation formula
intercept float independent term in decision function
alpha float the alpha parameter chosen by the information criterion
niter int number of iterations run by larspath to find the grid of alphas
criterion array shape nalphas The value of the information criteria ‘aic’ ‘bic’ across all alphas The alpha which has the smallest information criterion is chosen This value is larger by a factor of nsamples compared to Eqns 215 and 216 in Zou et al 2007

score self X y sampleweight Returns the coefficient of determination R2 of the pre
diction
setparams self params Set the parameters of this estimator
init selfcriterion’aic’ fitinterceptTrue verboseFalse normalizeTrue precom
pute’auto’ maxiter500 eps2220446049250313e16 copyXTrue positiveFalse
fitselfXycopyXNone
Fit the model using X y as training data
Parameters
Xarraylike shape nsamples nfeatures training data
yarraylike shape nsamples target values Will be cast to X’s dtype if necessary
copyX boolean optional default None If provided this parameter will override the
choice of copyX made at instance creation If True X will be copied else it may
be overwritten
Returns
self object returns an instance of self
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns

params mapping of string to any Parameter names mapped to their values
predictselfX
Predict using the linear model
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures Samples
Returns
Carray shape nsamples Returns predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
Examples using sklearnlinearmodelLassoLarsIC
•Lasso model selection CrossValidation AIC BIC

Out of Bag Estimates
When using ensemble methods base upon bagging ie generating new training sets using sampling with replacement part of the training set remains unused For each classifier in the ensemble a different part of the training set is left out
This left out portion can be used to estimate the generalization error without having to rely on a separate validation set This estimate comes “for free” as no additional data is needed and can be used for model selection
This is currently implemented in the following classes
ensembleRandomForestClassifier A random forest classifier
ensembleRandomForestRegressor A random forest regressor
ensembleExtraTreesClassifier An extratrees classifier
ensembleExtraTreesRegressor nestimators
An extratrees regressor
ensembleGradientBoostingClassifier loss
Gradient Boosting for classification
ensembleGradientBoostingRegressor loss
Gradient Boosting for regression

oobscoreFalse njobsNone
randomstateNone verbose0
warmstartFalse classweightNone
A random forest classifier
A random forest is a meta estimator that fits a number of decision tree classifiers on various subsamples of the dataset and uses averaging to improve the predictive accuracy and control overfitting The subsample size is always the same as the original input sample size but the samples are drawn with replacement if bootstrapTrue default
Read more in the User Guide
Parameters
nestimators integer optional default10 The number of trees in the forest
Changed in version 020 The default value of nestimators will change from 10 in version 020 to 100 in version 022
criterion string optional default”gini” The function to measure the quality of a split Sup ported criteria are “gini” for the Gini impurity and “entropy” for the information gain Note this parameter is treespecific
maxdepth integer or None optional defaultNone The maximum depth of the tree If None then nodes are expanded until all leaves are pure or until all leaves contain less than

minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided
maxfeatures int float string or None optional default”auto” The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturessqrtnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures same as “auto”
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed

New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
bootstrap boolean optional defaultTrue Whether bootstrap samples are used when build
ing trees If False the whole datset is used to build each tree
oobscore bool defaultFalse Whether to use outofbag samples to estimate the general
ization accuracy
njobs int or None optional defaultNone The number of jobs to run in parallel for both
fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity when fitting and predicting
warmstart bool optional defaultFalse When set to True reuse the solution of the pre
vious call to fit and add more estimators to the ensemble otherwise just fit a whole new
forest See the Glossary
classweight dict list of dicts “balanced” “balancedsubsample” or None optional de
faultNone Weights associated with classes in the form classlabel weight
If not given all classes are supposed to have weight one For multioutput problems a list
of dicts can be provided in the same order as the columns of y
Note that for multioutput including multilabel weights should be defined for each class of
every column in its own dict For example for fourclass multilabel classification weights
should be 0 1 1 1 0 1 1 5 0 1 1 1 0 1 1 1 instead of 11 25
31 41
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
The “balancedsubsample” mode is the same as “balanced” except that weights are com
puted based on the bootstrap sample for every tree grown
For multioutput the weights of each column of y will be multiplied
Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified
Attributes
estimators list of DecisionTreeClassifier The collection of fitted subestimators
classes array of shape nclasses or a list of such arrays The classes labels single output
problem or a list of arrays of class labels multioutput problem
nclasses int or list The number of classes single output problem or a list containing the
number of classes for each output multioutput problem

nfeatures int The number of features when fit is performed
noutputs int The number of outputs when fit is performed
featureimportances array of shape nfeatures Return the feature importances
the higher the more important the feature
oobscore float Score of the training dataset obtained using an outofbag estimate
oobdecisionfunction array of shape nsamples nclasses Decision function com
puted with outofbag estimate on the training set If nestimators is small it might
be possible that a data point was never left out during the bootstrap In this case
oobdecisionfunction might contain NaN
See also
DecisionTreeClassifier ExtraTreesClassifier
Notes
The default values for the parameters controlling the size of the trees eg maxdepth
minsamplesleaf etc lead to fully grown and unpruned trees which can potentially be very large on
some data sets To reduce memory consumption the complexity and size of the trees should be controlled by
setting those parameter values
The features are always randomly permuted at each split Therefore the best found split may vary even with
the same training data maxfeaturesnfeatures andbootstrapFalse if the improvement of the
criterion is identical for several splits enumerated during the search of the best split To obtain a deterministic
behaviour during fitting randomstate has to be fixed

applyselfX
Apply trees in the forest to X return leaf indices
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix
Returns
Xleaves arraylike shape nsamples nestimators For each datapoint x in X and for each tree in the forest return the index of the leaf x ends up in
decisionpath selfX
Return the decision path in the forest
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes
nnodesptr array of size nestimators 1 The columns from indicatornnodesptrinnodesptri1 gives the indicator value for the ith estimator
featureimportances
Return the feature importances the higher the more important the feature
Returns

featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXysampleweightNone
Build a forest of trees from the training set X y
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The training input sam
ples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix
is provided it will be converted into a sparse cscmatrix
yarraylike shape nsamples or nsamples noutputs The target values class labels
in classification real numbers in regression
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class for X
The predicted class of an input sample is a vote by the trees in the forest weighted by their probability
estimates That is the predicted class is the one with highest mean probability estimate across the trees
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
yarray of shape nsamples or nsamples noutputs The predicted classes
predictlogproba selfX
Predict class logprobabilities for X
The predicted class logprobabilities of an input sample is computed as the log of the mean predicted class
probabilities of the trees in the forest
Parameters

Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs
 1 The class probabilities of the input samples The order of the classes corresponds to
that in the attribute classes
predictproba selfX
Predict class probabilities for X
The predicted class probabilities of an input sample are computed as the mean predicted class probabilities
of the trees in the forest The class probability of a single tree is the fraction of samples of the same class
in a leaf
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs
 1 The class probabilities of the input samples The order of the classes corresponds to
that in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

A random forest regressor
A random forest is a meta estimator that fits a number of classifying decision trees on various subsamples of the dataset and uses averaging to improve the predictive accuracy and control overfitting The subsample size is always the same as the original input sample size but the samples are drawn with replacement if bootstrapTrue default
Read more in the User Guide
Parameters
nestimators integer optional default10 The number of trees in the forest
Changed in version 020 The default value of nestimators will change from 10 in version 020 to 100 in version 022
criterion string optional default"mse" The function to measure the quality of a split Sup ported criteria are "mse" for the mean squared error which is equal to variance reduction as feature selection criterion and "mae" for the mean absolute error
New in version 018 Mean Absolute Error MAE criterion
maxdepth integer or None optional defaultNone The maximum depth of the tree If None then nodes are expanded until all leaves are pure or until all leaves contain less than minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions

minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided
maxfeatures int float string or None optional default”auto” The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturesnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead

bootstrap boolean optional defaultTrue Whether bootstrap samples are used when build
ing trees If False the whole datset is used to build each tree
oobscore bool optional defaultFalse whether to use outofbag samples to estimate the
R2 on unseen data
njobs int or None optional defaultNone The number of jobs to run in parallel for both
fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom

getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict regression target for X

The predicted regression target of an input sample is computed as the mean predicted regression targets of the trees in the forest
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix
Returns
yarray of shape nsamples or nsamples noutputs The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred 2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score is 10 and it can be negative because the model can be arbitrarily worse A constant model that always predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may be a precomputed kernel matrix instead shape nsamples nsamplesfitted where nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage from version 023 to keep consistent with metricsr2score This will influence the score method of all the multioutput regressors except for multioutputMultiOutputRegressor To specify the default value manually and avoid the warning please either call metricsr2score directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self

An extratrees classifier
This class implements a meta estimator that fits a number of randomized decision trees aka extratrees on
various subsamples of the dataset and uses averaging to improve the predictive accuracy and control overfitting
Read more in the User Guide
Parameters
nestimators integer optional default10 The number of trees in the forest
Changed in version 020 The default value of nestimators will change from 10 in
version 020 to 100 in version 022
criterion string optional default"gini" The function to measure the quality of a split Sup
ported criteria are "gini" for the Gini impurity and "entropy" for the information gain
maxdepth integer or None optional defaultNone The maximum depth of the tree If
None then nodes are expanded until all leaves are pure or until all leaves contain less than
minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided

maxfeatures int float string or None optional default”auto” The number of features to consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures nfeatures features are considered at each split
• If “auto” then maxfeaturessqrtnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples is found even if it requires to effectively inspect more than maxfeatures features
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node NtL is the number of samples in the left child and NtR is the number of samples in the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of minimpuritydecrease in 019 The default value of minimpuritysplit will change from 1e7 to 0 in 023 and it will be removed in 025 Use minimpuritydecrease instead
bootstrap boolean optional defaultFalse Whether bootstrap samples are used when building trees If False the whole datset is used to build each tree
oobscore bool optional defaultFalse Whether to use outofbag samples to estimate the generalization accuracy
njobs int or None optional defaultNone The number of jobs to run in parallel for both fit andpredict None means 1 unless in a joblibparallelbackend context 1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int randomstate is the seed used by the random number generator If RandomState instance randomstate is the random number generator If None the random number generator is the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity when fitting and predicting

warmstart bool optional defaultFalse When set to True reuse the solution of the pre
vious call to fit and add more estimators to the ensemble otherwise just fit a whole new
forest See the Glossary
classweight dict list of dicts “balanced” “balancedsubsample” or None optional de
faultNone Weights associated with classes in the form classlabel weight
If not given all classes are supposed to have weight one For multioutput problems a list
of dicts can be provided in the same order as the columns of y
Note that for multioutput including multilabel weights should be defined for each class of
every column in its own dict For example for fourclass multilabel classification weights
should be 0 1 1 1 0 1 1 5 0 1 1 1 0 1 1 1 instead of 11 25
31 41
The “balanced” mode uses the values of y to automatically adjust weights inversely pro
portional to class frequencies in the input data as nsamples nclasses np
bincounty
The “balancedsubsample” mode is the same as “balanced” except that weights are com
puted based on the bootstrap sample for every tree grown
For multioutput the weights of each column of y will be multiplied
Note that these weights will be multiplied with sampleweight passed through the fit
method if sampleweight is specified
Attributes
estimators list of DecisionTreeClassifier The collection of fitted subestimators
classes array of shape nclasses or a list of such arrays The classes labels single output
problem or a list of arrays of class labels multioutput problem
nclasses int or list The number of classes single output problem or a list containing the
number of classes for each output multioutput problem
featureimportances array of shape nfeatures Return the feature importances
the higher the more important the feature
nfeatures int The number of features when fit is performed
noutputs int The number of outputs when fit is performed
oobscore float Score of the training dataset obtained using an outofbag estimate
oobdecisionfunction array of shape nsamples nclasses Decision function com
puted with outofbag estimate on the training set If nestimators is small it might
be possible that a data point was never left out during the bootstrap In this case
oobdecisionfunction might contain NaN
See also

applyselfX

Apply trees in the forest to X return leaf indices

Parameters

Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix

Returns

Xleaves arraylike shape nsamples nestimators For each datapoint x in X and for each tree in the forest return the index of the leaf x ends up in

decisionpath selfX

Return the decision path in the forest

New in version 018

Parameters

Xarraylike or sparse matrix shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix

Returns

indicator sparse csr array shape nsamples nnodes Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes

nnodesptr array of size nestimators 1 The columns from indica
tornnodesptrinnodesptri1 gives the indicator value for the ith estimator
featureimportances
Return the feature importances the higher the more important the feature
Returns
featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXysampleweightNone
Build a forest of trees from the training set X y
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The training input sam
ples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix
is provided it will be converted into a sparse cscmatrix
yarraylike shape nsamples or nsamples noutputs The target values class labels
in classification real numbers in regression
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class for X
The predicted class of an input sample is a vote by the trees in the forest weighted by their probability
estimates That is the predicted class is the one with highest mean probability estimate across the trees
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
yarray of shape nsamples or nsamples noutputs The predicted classes

predictlogproba selfX
Predict class logprobabilities for X
The predicted class logprobabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs 1 The class probabilities of the input samples The order of the classes corresponds to that in the attribute classes
predictproba selfX
Predict class probabilities for X
The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest The class probability of a single tree is the fraction of samples of the same class in a leaf
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted into a sparse csrmatrix
Returns
parray of shape nsamples nclasses or a list of noutputs such arrays if noutputs 1 The class probabilities of the input samples The order of the classes corresponds to that in the attribute classes
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have parameters of the form componentparameter so that it’s possible to update each component of a nested object
Returns
self

randomstateNone verbose0
warmstartFalse
An extratrees regressor
This class implements a meta estimator that fits a number of randomized decision trees aka extratrees on
various subsamples of the dataset and uses averaging to improve the predictive accuracy and control overfitting
Read more in the User Guide
Parameters
nestimators integer optional default10 The number of trees in the forest
Changed in version 020 The default value of nestimators will change from 10 in
version 020 to 100 in version 022
criterion string optional default"mse" The function to measure the quality of a split Sup
ported criteria are "mse" for the mean squared error which is equal to variance reduction as
feature selection criterion and "mae" for the mean absolute error
New in version 018 Mean Absolute Error MAE criterion
maxdepth integer or None optional defaultNone The maximum depth of the tree If
None then nodes are expanded until all leaves are pure or until all leaves contain less than
minsamplessplit samples
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression

• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided
maxfeatures int float string or None optional default”auto” The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturesnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
bootstrap boolean optional defaultFalse Whether bootstrap samples are used when build
ing trees If False the whole datset is used to build each tree
oobscore bool optional defaultFalse Whether to use outofbag samples to estimate the
R2 on unseen data

njobs int or None optional defaultNone The number of jobs to run in parallel for both
fit andpredict None means 1 unless in a joblibparallelbackend context
1means using all processors See Glossary for more details
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
verbose int optional default0 Controls the verbosity when fitting and predicting
warmstart bool optional defaultFalse When set to True reuse the solution of the pre
vious call to fit and add more estimators to the ensemble otherwise just fit a whole new
forest See the Glossary
Attributes
estimators list of DecisionTreeRegressor The collection of fitted subestimators
featureimportances array of shape nfeatures Return the feature importances
the higher the more important the feature
nfeatures int The number of features
noutputs int The number of outputs
oobscore float Score of the training dataset obtained using an outofbag estimate

applyselfX
Apply trees in the forest to X return leaf indices
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
Xleaves arraylike shape nsamples nestimators For each datapoint x in X and for
each tree in the forest return the index of the leaf x ends up in
decisionpath selfX
Return the decision path in the forest
New in version 018
Parameters
Xarraylike or sparse matrix shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
indicator sparse csr array shape nsamples nnodes Return a node indicator matrix
where non zero elements indicates that the samples goes through the nodes
nnodesptr array of size nestimators 1 The columns from indica
tornnodesptrinnodesptri1 gives the indicator value for the ith estimator
featureimportances
Return the feature importances the higher the more important the feature
Returns
featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXysampleweightNone
Build a forest of trees from the training set X y
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The training input sam
ples Internally its dtype will be converted to dtypenpfloat32 If a sparse matrix
is provided it will be converted into a sparse cscmatrix

yarraylike shape nsamples or nsamples noutputs The target values class labels
in classification real numbers in regression
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict regression target for X
The predicted regression target of an input sample is computed as the mean predicted regression targets of
the trees in the forest
Parameters
Xarraylike or sparse matrix of shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted into a sparse csrmatrix
Returns
yarray of shape nsamples or nsamples noutputs The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y

scikitlearn user guide Release 0213
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self

Gradient Boosting for classification
GB builds an additive model in a forward stagewise fashion it allows for the optimization of arbitrary differen
tiable loss functions In each stage nclasses regression trees are fit on the negative gradient of the binomial
or multinomial deviance loss function Binary classification is a special case where only a single regression tree
is induced
Read more in the User Guide
Parameters

loss ‘deviance’ ‘exponential’ optional default‘deviance’ loss function to be optimized
‘deviance’ refers to deviance logistic regression for classification with probabilistic out
puts For loss ‘exponential’ gradient boosting recovers the AdaBoost algorithm
learningrate float optional default01 learning rate shrinks the contribution of each tree
bylearningrate There is a tradeoff between learningrate and nestimators
nestimators int default100 The number of boosting stages to perform Gradient boosting
is fairly robust to overfitting so a large number usually results in better performance
subsample float optional default10 The fraction of samples to be used for fitting the in
dividual base learners If smaller than 10 this results in Stochastic Gradient Boosting
subsample interacts with the parameter nestimators Choosing subsample
10 leads to a reduction of variance and an increase in bias
criterion string optional default”friedmanmse” The function to measure the quality of
a split Supported criteria are “friedmanmse” for the mean squared error with improve
ment score by Friedman “mse” for mean squared error and “mae” for the mean absolute
error The default value of “friedmanmse” is generally the best as it can provide a better
approximation in some cases
New in version 018
minsamplessplit int float optional default2 The minimum number of samples required
to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit
nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required
to be at a leaf node A split point at any depth will only be considered if it leaves at least
minsamplesleaf training samples in each of the left and right branches This may
have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf
nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the
sum total of weights of all the input samples required to be at a leaf node Samples have
equal weight when sampleweight is not provided
maxdepth integer optional default3 maximum depth of the individual regression estima
tors The maximum depth limits the number of nodes in the tree Tune this parameter for
best performance the best value depends on the interaction of the input variables
minimpuritydecrease float optional default0 A node will be split if this split induces
a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity

whereNis the total number of samples Nt is the number of samples at the current node
NtL is the number of samples in the left child and NtR is the number of samples in
the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node
will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of
minimpuritydecrease in 019 The default value of minimpuritysplit
will change from 1e7 to 0 in 023 and it will be removed in 025 Use
minimpuritydecrease instead
init estimator or 'zero' optional defaultNone An estimator object that is used to compute
the initial predictions init has to provide fit andpredictproba If 'zero' the
initial raw predictions are set to zero By default a DummyEstimator predicting the
classes priors is used
randomstate int RandomState instance or None optional defaultNone If int ran
domstate is the seed used by the random number generator If RandomState instance
randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
maxfeatures int float string or None optional defaultNone The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If "auto" then maxfeaturessqrtnfeatures
• If "sqrt" then maxfeaturessqrtnfeatures
• If "log2" then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Choosingmaxfeatures nfeatures leads to a reduction of variance and an in
crease in bias
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
verbose int default 0 Enable verbose output If 1 then it prints progress and performance
once in a while the more trees the lower the frequency If greater than 1 then it prints
progress and performance for every tree
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
warmstart bool default False When set to True reuse the solution of the previous call to
fit and add more estimators to the ensemble otherwise just erase the previous solution See
the Glossary
presort bool or 'auto' optional default'auto' Whether to presort the data to speed up the
finding of best splits in fitting Auto mode by default will use presorting on dense data and

default to normal sorting on sparse data Setting presort to true on sparse data will raise an error
New in version 017 presort parameter
validationfraction float optional default 01 The proportion of training data to set aside as validation set for early stopping Must be between 0 and 1 Only used if niternochange is set to an integer
New in version 020
niternochange int default None niternochange is used to decide if early stop ping will be used to terminate training when validation score is not improving By de fault it is set to None to disable early stopping If set to a number it will set aside validationfraction size of the training data as validation and terminate training when validation score is not improving in all of the previous niternochange num bers of iterations The split is stratified
New in version 020
tolfloat optional default 1e4 Tolerance for the early stopping When the loss is not improv ing by at least tol for niternochange iterations if set to a number the training stops
New in version 020
Attributes
nestimators int The number of estimators as selected by early stopping if niternochange is specified Otherwise it is set to nestimators
New in version 020
featureimportances array shape nfeatures Return the feature importances the higher the more important the feature
oobimprovement array shape nestimators The improvement in loss deviance on the outofbag samples relative to the previous iteration oobimprovement0 is the improvement in loss of the first stage over the init estimator
trainscore array shape nestimators The ith score trainscorei is the de viance loss of the model at iteration ion the inbag sample If subsample 1 this is the deviance on the training data
loss LossFunction The concrete LossFunction object
init estimator The estimator that provides the initial predictions Set via the init argument orlossinitestimator
estimators ndarray of DecisionTreeRegressorshape nestimators lossK The collec tion of fitted subestimators lossK is 1 for binary classification otherwise nclasses
See also
sklearnensembleHistGradientBoostingClassifier

AdaBoostClassifier

Notes
The features are always randomly permuted at each split Therefore the best found split may vary even with the same training data and maxfeaturesnfeatures if the improvement of the criterion is identical for several splits enumerated during the search of the best split To obtain a deterministic behaviour during fitting randomstate has to be fixed

applyselfX
Apply trees in the ensemble to X return leaf indices
New in version 017
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided it will be converted to a sparse csrmatrix
Returns
Xleaves arraylike shape nsamples nestimators nclasses For each datapoint x in X and for each tree in the ensemble return the index of the leaf x ends up in each estimator

In the case of binary classification nclasses is 1
decisionfunction selfX
Compute the decision function of X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
score array shape nsamples nclasses or nsamples The decision function of the in
put samples which corresponds to the raw values predicted from the trees of the ensemble
 The order of the classes corresponds to that in the attribute classes Regression and
binary classification produce an array of shape nsamples
featureimportances
Return the feature importances the higher the more important the feature
Returns
featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXysampleweightNone monitorNone
Fit the gradient boosting model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
yarraylike shape nsamples Target values strings or integers in classification real
numbers in regression For classification labels must correspond to classes
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
monitor callable optional The monitor is called after each iteration with the current iter
ation a reference to the estimator and the local variables of fitstages as keyword
argumentscallablei self locals If the callable returns True the fit
ting procedure is stopped The monitor can be used for various things such as computing
heldout estimates early stopping model introspect and snapshoting
Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators

Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict class for X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
yarray shape nsamples The predicted values
predictlogproba selfX
Predict class logprobabilities for X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
parray shape nsamples nclasses The class logprobabilities of the input samples The
order of the classes corresponds to that in the attribute classes
Raises
AttributeError If theloss does not support probabilities
predictproba selfX
Predict class probabilities for X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
parray shape nsamples nclasses The class probabilities of the input samples The
order of the classes corresponds to that in the attribute classes
Raises
AttributeError If theloss does not support probabilities
scoreselfXysampleweightNone
Returns the mean accuracy on the given test data and labels
In multilabel classification this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted
Parameters
Xarraylike shape nsamples nfeatures Test samples
yarraylike shape nsamples or nsamples noutputs True labels for X
sampleweight arraylike shape nsamples optional Sample weights

Returns
score float Mean accuracy of selfpredictX wrt y
setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
stageddecisionfunction selfX
Compute decision function of Xfor each iteration
This method allows monitoring ie determine error on testing set after each stage
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
score generator of array shape nsamples k The decision function of the input sam
ples which corresponds to the raw values predicted from the trees of the ensemble The
classes corresponds to that in the attribute classes Regression and binary classification
are special cases with k 1 otherwise knclasses
stagedpredict selfX
Predict class at each stage for X
This method allows monitoring ie determine error on testing set after each stage
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
ygenerator of array of shape nsamples The predicted value of the input samples
stagedpredictproba selfX
Predict class probabilities at each stage for X
This method allows monitoring ie determine error on testing set after each stage
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
ygenerator of array of shape nsamples The predicted value of the input samples

Gradient Boosting for regression
GB builds an additive model in a forward stagewise fashion it allows for the optimization of arbitrary differ
entiable loss functions In each stage a regression tree is fit on the negative gradient of the given loss function
Read more in the User Guide
Parameters
loss 'ls' 'lad' 'huber' 'quantile' optional default'ls' loss function to be optimized 'ls'
refers to least squares regression 'lad' least absolute deviation is a highly robust loss
function solely based on order information of the input variables 'huber' is a combination
of the two 'quantile' allows quantile regression use alpha to specify the quantile
learningrate float optional default01 learning rate shrinks the contribution of each tree
bylearningrate There is a tradeoff between learningrate and nestimators
nestimators int default100 The number of boosting stages to perform Gradient boosting
is fairly robust to overfitting so a large number usually results in better performance
subsample float optional default10 The fraction of samples to be used for fitting the in
dividual base learners If smaller than 10 this results in Stochastic Gradient Boosting
subsample interacts with the parameter nestimators Choosing subsample
10 leads to a reduction of variance and an increase in bias
criterion string optional default"friedmanmse" The function to measure the quality of
a split Supported criteria are "friedmanmse" for the mean squared error with improve
ment score by Friedman "mse" for mean squared error and "mae" for the mean absolute
error The default value of "friedmanmse" is generally the best as it can provide a better
approximation in some cases

New in version 018
minsamplessplit int float optional default2 The minimum number of samples required to split an internal node
• If int then consider minsamplessplit as the minimum number
• If float then minsamplessplit is a fraction and ceilminsamplessplit nsamples are the minimum number of samples for each split
Changed in version 018 Added float values for fractions
minsamplesleaf int float optional default1 The minimum number of samples required to be at a leaf node A split point at any depth will only be considered if it leaves at least minsamplesleaf training samples in each of the left and right branches This may have the effect of smoothing the model especially in regression
• If int then consider minsamplesleaf as the minimum number
• If float then minsamplesleaf is a fraction and ceilminsamplesleaf nsamples are the minimum number of samples for each node
Changed in version 018 Added float values for fractions
minweightfractionleaf float optional default0 The minimum weighted fraction of the sum total of weights of all the input samples required to be at a leaf node Samples have equal weight when sampleweight is not provided
maxdepth integer optional default3 maximum depth of the individual regression estima tors The maximum depth limits the number of nodes in the tree Tune this parameter for best performance the best value depends on the interaction of the input variables
minimpuritydecrease float optional default0 A node will be split if this split induces a decrease of the impurity greater than or equal to this value
The weighted impurity decrease equation is the following
Nt N impurity NtR Nt rightimpurity
 NtL Nt leftimpurity
whereNis the total number of samples Nt is the number of samples at the current node NtL is the number of samples in the left child and NtR is the number of samples in the right child
NNtNtR andNtL all refer to the weighted sum if sampleweight is passed
New in version 019
minimpuritysplit float default1e7 Threshold for early stopping in tree growth A node will split if its impurity is above the threshold otherwise it is a leaf
Deprecated since version 019 minimpuritysplit has been deprecated in favor of minimpuritydecrease in 019 The default value of minimpuritysplit will change from 1e7 to 0 in 023 and it will be removed in 025 Use minimpuritydecrease instead
init estimator or ‘zero’ optional defaultNone An estimator object that is used to compute the initial predictions init has to provide fit andpredict If ‘zero’ the initial raw predictions are set to zero By default a DummyEstimator is used predicting either the average target value for loss’ls’ or a quantile for the other losses
randomstate int RandomState instance or None optional defaultNone If int ran domstate is the seed used by the random number generator If RandomState instance

randomstate is the random number generator If None the random number generator is
the RandomState instance used by nprandom
maxfeatures int float string or None optional defaultNone The number of features to
consider when looking for the best split
• If int then consider maxfeatures features at each split
• If float then maxfeatures is a fraction and intmaxfeatures
nfeatures features are considered at each split
• If “auto” then maxfeaturesnfeatures
• If “sqrt” then maxfeaturessqrtnfeatures
• If “log2” then maxfeatureslog2nfeatures
• If None then maxfeaturesnfeatures
Choosingmaxfeatures nfeatures leads to a reduction of variance and an in
crease in bias
Note the search for a split does not stop until at least one valid partition of the node samples
is found even if it requires to effectively inspect more than maxfeatures features
alpha float default09 The alphaquantile of the huber loss function and the quantile loss
function Only if losshuber orlossquantile
verbose int default 0 Enable verbose output If 1 then it prints progress and performance
once in a while the more trees the lower the frequency If greater than 1 then it prints
progress and performance for every tree
maxleafnodes int or None optional defaultNone Grow trees with maxleafnodes
in bestfirst fashion Best nodes are defined as relative reduction in impurity If None then
unlimited number of leaf nodes
warmstart bool default False When set to True reuse the solution of the previous call to
fit and add more estimators to the ensemble otherwise just erase the previous solution See
the Glossary
presort bool or ‘auto’ optional default‘auto’ Whether to presort the data to speed up the
finding of best splits in fitting Auto mode by default will use presorting on dense data and
default to normal sorting on sparse data Setting presort to true on sparse data will raise an
error
New in version 017 optional parameter presort
validationfraction float optional default 01 The proportion of training data to set
aside as validation set for early stopping Must be between 0 and 1 Only used if
niternochange is set to an integer
New in version 020
niternochange int default None niternochange is used to decide if early stop
ping will be used to terminate training when validation score is not improving By de
fault it is set to None to disable early stopping If set to a number it will set aside
validationfraction size of the training data as validation and terminate training
when validation score is not improving in all of the previous niternochange num
bers of iterations
New in version 020

tolfloat optional default 1e4 Tolerance for the early stopping When the loss is not improv
ing by at least tol for niternochange iterations if set to a number the training
stops
New in version 020
Attributes
featureimportances array shape nfeatures Return the feature importances the
higher the more important the feature
oobimprovement array shape nestimators The improvement in loss deviance on
the outofbag samples relative to the previous iteration oobimprovement0 is the
improvement in loss of the first stage over the init estimator
trainscore array shape nestimators The ith score trainscorei is the de
viance loss of the model at iteration ion the inbag sample If subsample 1
this is the deviance on the training data
loss LossFunction The concrete LossFunction object
init estimator The estimator that provides the initial predictions Set via the init argument
orlossinitestimator
estimators array of DecisionTreeRegressor shape nestimators 1 The collection of fitted
subestimators
See also
sklearnensembleHistGradientBoostingRegressor

applyselfX
Apply trees in the ensemble to X return leaf indices
New in version 017
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally its dtype will be converted to dtypenpfloat32 If a sparse matrix is provided
it will be converted to a sparse csrmatrix
Returns
Xleaves arraylike shape nsamples nestimators For each datapoint x in X and for
each tree in the ensemble return the index of the leaf x ends up in each estimator
featureimportances
Return the feature importances the higher the more important the feature
Returns
featureimportances array shape nfeatures The values of this array sum to 1 unless
all trees are single node trees consisting of only the root node in which case it will be an
array of zeros
fitselfXysampleweightNone monitorNone
Fit the gradient boosting model
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
yarraylike shape nsamples Target values strings or integers in classification real
numbers in regression For classification labels must correspond to classes
sampleweight arraylike shape nsamples or None Sample weights If None then
samples are equally weighted Splits that would create child nodes with net zero or neg
ative weight are ignored while searching for a split in each node In the case of classifi
cation splits are also ignored if they would result in any single class carrying a negative
weight in either child node
monitor callable optional The monitor is called after each iteration with the current iter
ation a reference to the estimator and the local variables of fitstages as keyword

argumentscallablei self locals If the callable returns True the fit
ting procedure is stopped The monitor can be used for various things such as computing

Returns
self object
getparams selfdeepTrue
Get parameters for this estimator
Parameters
deep boolean optional If True will return the parameters for this estimator and contained
subobjects that are estimators
Returns
params mapping of string to any Parameter names mapped to their values
predictselfX
Predict regression target for X
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
yarray shape nsamples The predicted values
scoreselfXysampleweightNone
Returns the coefficient of determination R2 of the prediction
The coefficient R2 is defined as 1 uv where u is the residual sum of squares ytrue ypred
2sum and v is the total sum of squares ytrue ytruemean 2sum The best possible score
is 10 and it can be negative because the model can be arbitrarily worse A constant model that always
predicts the expected value of y disregarding the input features would get a R2 score of 00
Parameters
Xarraylike shape nsamples nfeatures Test samples For some estimators this may
be a precomputed kernel matrix instead shape nsamples nsamplesfitted where
nsamplesfitted is the number of samples used in the fitting for the estimator
yarraylike shape nsamples or nsamples noutputs True values for X
sampleweight arraylike shape nsamples optional Sample weights
Returns
score float R2 of selfpredictX wrt y
Notes
The R2 score used when calling score on a regressor will use multioutputuniformaverage
from version 023 to keep consistent with metricsr2score This will influence the score
method of all the multioutput regressors except for multioutputMultiOutputRegressor
To specify the default value manually and avoid the warning please either call metricsr2score
directly or make a custom scorer with metricsmakescorer the builtin scorer r2 uses
multioutputuniformaverage

setparams selfparams
Set the parameters of this estimator
The method works on simple estimators as well as on nested objects such as pipelines The latter have
parameters of the form componentparameter so that it’s possible to update each component
of a nested object
Returns
self
stagedpredict selfX
Predict regression target at each stage for X
This method allows monitoring ie determine error on testing set after each stage
Parameters
Xarraylike sparse matrix shape nsamples nfeatures The input samples Inter
nally it will be converted to dtypenpfloat32 and if a sparse matrix is provided to
a sparsecsrmatrix
Returns
ygenerator of array of shape nsamples The predicted value of the input samples

•Gradient Boosting regression
•Partial Dependence Plots
333 Model evaluation quantifying the quality of predictions
There are 3 different APIs for evaluating the quality of a model’s predictions
•Estimator score method Estimators have a score method providing a default evaluation criterion for the
problem they are designed to solve This is not discussed on this page but in each estimator’s documentation
•Scoring parameter Modelevaluation tools using crossvalidation such asmodelselection
crossvalscore andmodelselectionGridSearchCV rely on an internal scoring strategy This
is discussed in the section The scoring parameter defining model evaluation rules
•Metric functions Themetrics module implements functions assessing prediction error for specific purposes
These metrics are detailed in sections on Classification metrics Multilabel ranking metrics Regression metrics
andClustering metrics
Finally Dummy estimators are useful to get a baseline value of those metrics for random predictions
See also
For “pairwise” metrics between samples and not estimators or predictions see the Pairwise metrics Affinities and
Kernels section

Thescoring parameter defining model evaluation rules
Model selection and evaluation using tools such as modelselectionGridSearchCV and
modelselectioncrossvalscore take ascoring parameter that controls what metric they ap
ply to the estimators evaluated
Common cases predefined values
For the most common use cases you can designate a scorer object with the scoring parameter the table below
shows all possible values All scorer objects follow the convention that higher return values are better than
lower return values Thus metrics which measure the distance between the model and the data like metrics
meansquarederror are available as negmeansquarederror which return the negated value of the metric

‘→SCORERSkeys to get valid options
```
Note The values listed by the ValueError exception correspond to the functions measuring prediction accuracy described in the following sections The scorer objects for those functions are stored in the dictionary sklearn metricsSCORERS

Defining your scoring strategy from metric functions

The module sklearnmetrics also exposes a set of simple functions measuring a prediction error given ground truth and prediction

- functions ending with score return a value to maximize the higher the better
- functions ending with error orloss return a value to minimize the lower the better When converting into a scorer object using makescorer set thegreaterisbetter parameter to False True by default see the parameter description below

Metrics available for various machine learning tasks are detailed in sections below

Many metrics are not given names to be used as scoring values sometimes because they require additional param eters such as fbetascore In such cases you need to generate an appropriate scoring object The simplest way to generate a callable object for scoring is by using makescorer That function converts metrics into callables that can be used for model evaluation

One typical use case is to wrap an existing metric function from the library with nondefault values for its parameters such as the beta parameter for the fbetascore function

```
 from sklearnmetrics import fbetascore makescorer
ftwoscorer  makescorerfbetascore beta2
 from sklearnmodelselection import GridSearchCV
 from sklearnsvm import LinearSVC
grid  GridSearchCVLinearSVC paramgridC 1 10
 scoringftwoscorer cv5
```
The second use case is to build a completely custom scorer object from a simple python function using makescorer which can take several parameters

- the python function you want to use mycustomlossfunc in the example below
- whether the python function returns a score greaterisbetterTrue the default or a loss greaterisbetterFalse If a loss the output of the python function is negated by the scorer ob ject conforming to the cross validation convention that scorers return higher values for better models
- for classification metrics only whether the python function you provided requires continuous decision certain ties needsthresholdTrue The default value is False
- any additional parameters such as beta orlabels inf1score

Here is an example of building custom scorers and of using the greaterisbetter parameter

```
 import numpy as np
 def mycustomlossfuncytrue ypred
 diff  npabsytrue  ypredmax
 return nplog1pdiff

 score will negate the return value of mycustomlossfunc
 which will be nplog2 0693 given the values for X
 and y defined below
score  makescorermycustomlossfunc greaterisbetter False
X  1 1
y  0 1
 from sklearndummy import DummyClassifier
clf  DummyClassifierstrategymostfrequent randomstate0
clf  clffitX y
mycustomlossfuncclfpredictX y
069
scoreclf X y
069
```

Implementing your own scoring object

You can generate even more flexible model scorers by constructing your own scoring object from scratch without using themakescorer factory For a callable to be a scorer it needs to meet the protocol specified by the following two rules

• It can be called with parameters estimator X y whereestimator is the model that should be evaluatedXis validation data and yis the ground truth target for Xin the supervised case or None in the unsupervised case

• It returns a floating point number that quantifies the estimator prediction quality on X with reference to y

Again by convention higher numbers are better so if your scorer returns loss that value should be negated

Note Using custom scorers in functions where njobs 1

While defining the custom scoring function alongside the calling function should work out of the box with the default joblib backend loky importing it from another module will be a more robust approach and work independently of the joblib backend

For example to use njobs greater than 1 in the example below customscoringfunction function is saved in a usercreated module customscorermodulepy and imported

```
 from customscorermodule import customscoringfunction
crossvalscoremodel
Xtrain
ytrain
scoringmakescorercustomscoringfunction greaterisbetter False
cv5
njobs1
```

Using multiple metric evaluation
Scikitlearn also permits evaluation of multiple metrics in GridSearchCV RandomizedSearchCV and crossvalidate
There are two ways to specify multiple scoring metrics for the scoring parameter
•As an iterable of string metrics
scoring accuracy precision
•As adict mapping the scorer name to the scoring function
 from sklearnmetrics import accuracyscore
 from sklearnmetrics import makescorer
scoring accuracy makescoreraccuracyscore
 prec precision
Note that the dict values can either be scorer functions or one of the predefined metric strings
Currently only those scorer functions that return a single score can be passed inside the dict Scorer functions that return multiple values are not permitted and will require a wrapper to return a single metric
 from sklearnmodelselection import crossvalidate

Classification metrics
Thesklearnmetrics module implements several loss score and utility functions to measure classification performance Some metrics might require probability estimates of the positive class confidence values or binary decisions values Most implementations allow each sample to provide a weighted contribution to the overall score through thesampleweight parameter
Some of these are restricted to the binary classification case
precisionrecallcurve ytrue probaspred Compute precisionrecall pairs for different probability thresholds
roccurve ytrue yscore poslabel Compute Receiver operating characteristic ROC
balancedaccuracyscore ytrue ypred Compute the balanced accuracy

Others also work in the multiclass case
cohenkappascore y1 y2 labels weights Cohen’s kappa a statistic that measures interannotator agreement
confusionmatrix ytrue ypred labels Compute confusion matrix to evaluate the accuracy of a classification
hingeloss ytrue preddecision labels Average hinge loss nonregularized
matthewscorrcoef ytrue ypred Compute the Matthews correlation coefficient MCC
Some also work in the multilabel case
accuracyscore ytrue ypred normalize Accuracy classification score
classificationreport ytrue ypred Build a text report showing the main classification metrics
f1score ytrue ypred labels Compute the F1 score also known as balanced Fscore or Fmeasure
fbetascore ytrue ypred beta labels Compute the Fbeta score
hammingloss ytrue ypred labels Compute the average Hamming loss
jaccardscore ytrue ypred labels Jaccard similarity coefficient score
logloss ytrue ypred eps normalize Log loss aka logistic loss or crossentropy loss
multilabelconfusionmatrix ytrue ypred Compute a confusion matrix for each class or sample
precisionrecallfscoresupport ytrue ypredCompute precision recall Fmeasure and support for each class
precisionscore ytrue ypred labels Compute the precision
recallscore ytrue ypred labels Compute the recall
zerooneloss ytrue ypred normalize Zeroone classification loss
And some work with binary and multilabel but not multiclass problems
averageprecisionscore ytrue yscore Compute average precision AP from prediction scores
rocaucscore ytrue yscore average Compute Area Under the Receiver Operating Characteris tic Curve ROC AUC from prediction scores
In the following subsections we will describe each of those functions preceded by some notes on common API and metric definition
From binary to multiclass and multilabel
Some metrics are essentially defined for binary classification tasks eg f1score rocaucscore In these cases by default only the positive label is evaluated assuming by default that the positive class is labelled 1though this may be configurable through the poslabel parameter
In extending a binary metric to multiclass or multilabel problems the data is treated as a collection of binary problems one for each class There are then a number of ways to average binary metric calculations across the set of classes each of which may be useful in some scenario Where available you should select among these using the average parameter
•macro simply calculates the mean of the binary metrics giving equal weight to each class In problems where infrequent classes are nonetheless important macroaveraging may be a means of highlighting their performance On the other hand the assumption that all classes are equally important is often untrue such that macroaveraging will overemphasize the typically low performance on an infrequent class

•weighted accounts for class imbalance by computing the average of binary metrics in which each class’s score is weighted by its presence in the true data sample
•micro gives each sampleclass pair an equal contribution to the overall metric except as a result of sample weight Rather than summing the metric per class this sums the dividends and divisors that make up the perclass metrics to calculate an overall quotient Microaveraging may be preferred in multilabel settings including multiclass classification where a majority class is to be ignored
•samples applies only to multilabel problems It does not calculate a perclass measure instead calculating the metric over the true and predicted classes for each sample in the evaluation data and returning their sampleweight weighted average
• Selecting averageNone will return an array with the score for each class
While multiclass data is provided to the metric like binary targets as an array of class labels multilabel data is specified as an indicator matrix in which cell i j has value 1 if sample ihas labeljand value 0 otherwise
Accuracy score
Theaccuracyscore function computes the accuracy either the fraction default or the count normalizeFalse of correct predictions
In multilabel classification the function returns the subset accuracy If the entire set of predicted labels for a sample strictly match with the true set of labels then the subset accuracy is 10 otherwise it is 00
If□□is the predicted value of the □th sample and □□is the corresponding true value then the fraction of correct predictions over □samples is defined as
accuracy □□ 1
□samples□samples−1∑
□01□□□□
where 1□is the indicator function
```
 import numpy as np
 from sklearnmetrics import accuracyscore
ypred  0 2 1 3
ytrue  0 1 2 3
accuracyscoreytrue ypred
05
accuracyscoreytrue ypred normalize False
2
```
In the multilabel case with binary label indicators
```
accuracyscorenparray0 1 1 1 npones2 2
05
```
Example
• See Test with permutations the significance of a classification score for an example of accuracy score usage using permutations of the dataset

Balanced accuracy score
Thebalancedaccuracyscore function computes the balanced accuracy which avoids inflated performance estimates on imbalanced datasets It is the macroaverage of recall scores per class or equivalently raw accuracy where each sample is weighted according to the inverse prevalence of its true class Thus for balanced datasets the score is equal to accuracy
In the binary case balanced accuracy is equal to the arithmetic mean of sensitivity true positive rate and specificity true negative rate or the area under the ROC curve with binary predictions rather than scores
If the classifier performs equally well on either class this term reduces to the conventional accuracy ie the number of correct predictions divided by the total number of predictions
In contrast if the conventional accuracy is above chance only because the classifier takes advantage of an imbalanced test set then the balanced accuracy as appropriate will drop to1
□□□□□□□□
The score ranges from 0 to 1 or when adjustedTrue is used it rescaled to the range1
1−□□□□□□□□to 1 inclusive
with performance at random scoring 0
If□□is the true value of the □th sample and □□is the corresponding sample weight then we adjust the sample weight to
□□□□∑
□1□□□□□□
where 1□is the indicator function Given predicted □□for sample □ balanced accuracy is defined as
balancedaccuracy □□ □ 1∑□□∑
□1□□□□ □□
WithadjustedTrue balanced accuracy reports the relative increase from balancedaccuracy □0 □
1
□□□□□□□□ In the binary case this is also known as Youden’s J statistic or informedness
Note The multiclass definition here seems the most reasonable extension of the metric used in binary classification though there is no certain consensus in the literature
• Our definition Mosley2013 Kelleher2015 andGuyon2015 where Guyon2015 adopt the adjusted version to ensure that random predictions have a score of 0and perfect predictions have a score of 1
• Class balanced accuracy as described in Mosley2013 the minimum between the precision and the recall for each class is computed Those values are then averaged over the total number of classes to get the balanced accuracy
• Balanced Accuracy as described in Urbanowicz2015 the average of sensitivity and specificity is computed for each class and then averaged over total number of classes
References
Cohen’s kappa
The function cohenkappascore computes Cohen’s kappa statistic This measure is intended to compare labelings by different human annotators not a classifier versus a ground truth
The kappa score see docstring is a number between 1 and 1 Scores above 8 are generally considered good agreement zero or lower means no agreement practically random labels

Kappa scores can be computed for binary or multiclass problems but not for multilabel problems except by manually computing a perlabel score and not for more than two annotators

```
 from sklearnmetrics import cohenkappascore
ytrue  2 0 2 2 0 1
ypred  0 0 2 2 0 2
cohenkappascoreytrue ypred
04285714285714286
```

Confusion matrix

Theconfusionmatrix function evaluates classification accuracy by computing the confusion matrix with each row corresponding to the true class httpsenwikipediaorgwikiConfusionmatrix‘ Wikipedia and other references may use different convention for axes

By definition entry □ □in a confusion matrix is the number of observations actually in group □ but predicted to be in group □ Here is an example

```
 from sklearnmetrics import confusionmatrix
ytrue  2 0 2 2 0 1
ypred  0 0 2 2 0 2
confusionmatrixytrue ypred
array2 0 0
0 0 1
1 0 2
```

Here is a visual representation of such a confusion matrix this figure comes from the Confusion matrix example

For binary problems we can get counts of true negatives false positives false negatives and true positives as follows

```
ytrue  0 0 0 1 1 1 1 1
ypred  0 1 0 1 0 1 0 1
tn fp fn tp  confusionmatrixytrue ypredravel
```

tn fp fn tp
2 1 2 3
Example
• See Confusion matrix for an example of using a confusion matrix to evaluate classifier output quality
• See Recognizing handwritten digits for an example of using a confusion matrix to classify handwritten digits
• See Classification of text documents using sparse features for an example of using a confusion matrix to classify text documents
Classification report
Theclassificationreport function builds a text report showing the main classification metrics Here is a small example with custom targetnames and inferred labels
```
 from sklearnmetrics import classificationreport
ytrue  0 1 2 2 0
ypred  0 0 2 1 0
targetnames  class 0 class 1 class 2
printclassificationreportytrue ypred targetnamestargetnames
```
precision recall f1score support
class 0 067 100 080 2
class 1 000 000 000 1
class 2 100 050 067 2
accuracy 060 5
macro avg 056 050 049 5
weighted avg 067 060 059 5
Example
• See Recognizing handwritten digits for an example of classification report usage for handwritten digits
• See Classification of text documents using sparse features for an example of classification report usage for text documents
• See Parameter estimation using grid search with crossvalidation for an example of classification report usage for grid search with nested crossvalidation
Hamming loss
Thehammingloss computes the average Hamming loss or Hamming distance between two sets of samples
If□□is the predicted value for the □th label of a given sample □□is the corresponding true value and □labels is the number of classes or labels then the Hamming loss □□□□□□□□ between two samples is defined as
□□□□□□□□ □□ 1
□labels□labels−1∑
□01□□□□

where 1□is the indicator function
```
 from sklearnmetrics import hammingloss
ypred  1 2 3 4
ytrue  2 2 3 4
hammingglossytrue ypred
```
025
In the multilabel case with binary label indicators
```
hammingglossnparray0 1 1 1 npzeros2 2
```
075
Note In multiclass classification the Hamming loss corresponds to the Hamming distance between ytrue and ypred which is similar to the Zero one loss function However while zeroone loss penalizes prediction sets that do not strictly match true sets the Hamming loss penalizes individual labels Thus the Hamming loss upper bounded by the zeroone loss is always between zero and one inclusive and predicting a proper subset or superset of the true labels will give a Hamming loss between zero and one exclusive

Precision recall and Fmeasures

Intuitively precision is the ability of the classifier not to label as positive a sample that is negative and recall is the ability of the classifier to find all the positive samples

The Fmeasure □□and□1measures can be interpreted as a weighted harmonic mean of the precision and recall A □□measure reaches its best value at 1 and its worst score at 0 With □ 1□□and□1are equivalent and the recall and the precision are equally important

Theprecisionrecallcurve computes a precisionrecall curve from the ground truth label and a score given by the classifier by varying a decision threshold

Theaverageprecisionscore function computes the average precision AP from prediction scores The value is between 0 and 1 and higher is better AP is defined as

AP∑
□□□−□□−1□□

where □□and□□are the precision and recall at the nth threshold With random predictions the AP is the fraction of positive samples

References Manning2008 andEveringham2010 present alternative variants of AP that interpolate the precision recall curve Currently averageprecisionscore does not implement any interpolated variant References Davis2006 andFlach2015 describe why a linear interpolation of points on the precisionrecall curve provides an overlyoptimistic measure of classifier performance This linear interpolation is used when computing area under the curve with the trapezoidal rule in auc

Several functions allow you to analyze the precision recall and Fmeasures score

averageprecisionscore ytrue yscore Compute average precision AP from prediction scores
f1score ytrue ypred labels Compute the F1 score also known as balanced Fscore or Fmeasure
fbetascore ytrue ypred beta labels Compute the Fbeta score
precisionrecallcurve ytrue probaspred Compute precisionrecall pairs for different probability thresholds

Binary classification
In a binary classification task the terms ‘‘positive” and ‘‘negative” refer to the classifier’s prediction and the terms
‘‘true” and ‘‘false” refer to whether that prediction corresponds to the external judgment sometimes known as the
‘‘observation‘‘ Given these definitions we can formulate the following table
Actual class observation
Predicted class expectation tp true positive Correct result fp false positive Unexpected result
fn false negative Missing result tn true negative Correct absence of result
In this context we can define the notions of precision recall and Fmeasure
precision □□
□□□□
recall □□
□□□□
□□ 1 □2precision×recall
□2precision recall

Multiclass and multilabel classification
In multiclass and multilabel classification task the notions of precision recall and Fmeasures can be ap
plied to each label independently There are a few ways to combine results across labels specified by the
average argument to the averageprecisionscore multilabel only f1score fbetascore
precisionrecallfscoresupport precisionscore andrecallscore functions as described
above Note that if all labels are included “micro”averaging in a multiclass setting will produce precision recall and
□that are all identical to accuracy Also note that “weighted” averaging may produce an Fscore that is not between
precision and recall
To make this more explicit consider the following notation
•□the set of predicted □□□□□□ □□□□□ pairs
•□the set of true□□□□□□ □□□□□ pairs
•□the set of labels
•□the set of samples
•□□the subset of □with sample □ ie□□′ □∈□□′□
•□□the subset of □with label □
• similarly □□and□□are subsets of □
•□□ □ □∩□

Hinge loss
Thehingeloss function computes the average distance between the model and the data using hinge loss a one sided metric that considers only prediction errors Hinge loss is used in maximal margin classifiers such as support vector machines
If the labels are encoded with 1 and 1 □ is the true value and □is the predicted decisions as output by decisionfunction then the hinge loss is defined as
□Hinge□ □ max1−□□01−□□
If there are more than two labels hingeloss uses a multiclass variant due to Crammer Singer Here is the paper describing it
If□□is the predicted decision for true label and □□is the maximum of the predicted decisions for all other labels where predicted decisions are output by decision function then multiclass hinge loss is defined by
□Hinge□□ □□ max1 □□−□□0
Here a small example demonstrating the use of the hingeloss function with a svm classifier in a binary class problem
```
 from sklearn import svm
 from sklearnmetrics import hingeloss
X  0 1

Log loss
Log loss also called logistic regression loss or crossentropy loss is defined on probability estimates It is commonly used in multinomial logistic regression and neural networks as well as in some variants of expectationmaximization and can be used to evaluate the probability outputs predictproba of a classifier instead of its discrete predictions
For binary classification with a true label □∈01and a probability estimate □ Pr □ 1 the log loss per sample is the negative loglikelihood of the classifier given the true label
□log□ □ −log Pr □□ −□log□ 1−□ log1−□
This extends to the multiclass case as follows Let the true labels for a set of samples be encoded as a 1ofK binary indicator matrix □ ie □□□ 1if sample □has label □taken from a set of □labels Let □be a matrix of probability estimates with □□□ Pr □□□ 1 Then the log loss of the whole set is
□log□ □ −log Pr □□ −1
□□−1∑
□0□−1∑
□0□□□log□□□
To see how this generalizes the binary log loss given above note that in the binary case □□0 1−□□1and□□0 1−□□1 so expanding the inner sum over □□□∈01gives the binary log loss
Thelogloss function computes log loss given a list of groundtruth labels and a probability matrix as returned by an estimator’s predictproba method
 from sklearnmetrics import logloss
ytrue 0 0 1 1

ypred 9 1 8 2 3 7 01 99
loglossytrue ypred
01738
The first9 1 inypred denotes 90 probability that the first sample has label 0 The log loss is nonnegative
Matthews correlation coefficient
Thematthewscorrcoef function computes the Matthew’s correlation coefficient MCC for binary classes
Quoting Wikipedia
“The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary
twoclass classifications It takes into account true and false positives and negatives and is generally
regarded as a balanced measure which can be used even if the classes are of very different sizes The
MCC is in essence a correlation coefficient value between 1 and 1 A coefficient of 1 represents
a perfect prediction 0 an average random prediction and 1 an inverse prediction The statistic is also
known as the phi coefficient”
In the binary twoclass case □□□□□□and□□are respectively the number of true positives true negatives false
positives and false negatives the MCC is defined as
□□□ □□×□□−□□×□□√
□□□□□□□□□□□□□□□□□□
In the multiclass case the Matthews correlation coefficient can be defined in terms of a confusionmatrix □for
□classes To simplify the definition consider the following intermediate variables
•□□∑□
□□□□the number of times class □truly occurred
•□□∑□
□□□□the number of times class □was predicted
•□∑□
□□□□the total number of samples correctly predicted
•□∑□
□∑□
□□□□the total number of samples
Then the multiclass MCC is defined as
□□□ □×□−∑□
□□□×□□√
□2−∑□
□□2
□×□2−∑□
□□2
□
When there are more than two labels the value of the MCC will no longer range between 1 and 1 Instead the
minimum value will be somewhere between 1 and 0 depending on the number and distribution of ground true labels
The maximum value is always 1
Here is a small example illustrating the usage of the matthewscorrcoef function
 from sklearnmetrics import matthewscorrcoef
ytrue 1 1 1 1
ypred 1 1 1 1
matthewscorrcoefytrue ypred
033
Multilabel confusion matrix
Themultilabelconfusionmatrix function computes classwise default or samplewise sample
wiseTrue multilabel confusion matrix to evaluate the accuracy of a classification multilabelconfusionmatrix

also treats multiclass data as if it were multilabel as this is a transformation commonly applied to evaluate multiclass problems with binary classification metrics such as precision recall etc
When calculating classwise multilabel confusion matrix the count of true negatives for class is00 false negatives is 10 true positives is 11and false positives is 01
Here is an example demonstrating the use of the multilabelconfusionmatrix function with multilabel indicator matrix input
```
 import numpy as np
 from sklearnmetrics import multilabelconfusionmatrix
ytrue  nparray1 0 1
 0 1 0
ypred  nparray1 0 0
 0 1 1
multilabelconfusionmatrixytrue ypred
array1 0
0 1
1 0
0 1
0 1
1 0
```
Or a confusion matrix can be constructed for each sample’s labels
```
multilabelconfusionmatrixytrue ypred samplewise True
array1 0
1 1
1 1
0 1
```
Here is an example demonstrating the use of the multilabelconfusionmatrix function with multiclass input
```

Receiver operating characteristic ROC
The function roccurve computes the receiver operating characteristic curve or ROC curve Quoting Wikipedia
“A receiver operating characteristic ROC or simply ROC curve is a graphical plot which illustrates
the performance of a binary classifier system as its discrimination threshold is varied It is created by
plotting the fraction of true positives out of the positives TPR true positive rate vs the fraction of false
positives out of the negatives FPR false positive rate at various threshold settings TPR is also known
as sensitivity and FPR is one minus the specificity or true negative rate”
This function requires the true binary value and the target scores which can either be probability estimates of the
positive class confidence values or binary decisions Here is a small example of how to use the roccurve function
 import numpy as np
 from sklearnmetrics import roccurve
y nparray1 1 2 2
scores nparray01 04 035 08
fpr tpr thresholds roccurvey scores poslabel2
fpr
array0 0 05 05 1
tpr
array0 05 05 1 1
thresholds
array18 08 04 035 01

This figure shows an example of such an ROC curve
Therocaucscore function computes the area under the receiver operating characteristic ROC curve which is
also denoted by AUC or AUROC By computing the area under the roc curve the curve information is summarized in
one number For more information see the Wikipedia article on AUC
```
 import numpy as np
 from sklearnmetrics import rocaucscore
ytrue  nparray0 0 1 1
yscores  nparray01 04 035 08
rocaucscoreytrue yscores
```
075
In multilabel classification the rocaucscore function is extended by averaging over the labels as above
Compared to metrics such as the subset accuracy the Hamming loss or the F1 score ROC doesn’t require optimizing a
threshold for each label The rocaucscore function can also be used in multiclass classification if the predicted
outputs have been binarized
In applications where a high false positive rate is not tolerable the parameter maxfpr
ofrocaucscore can be used to summarize the ROC curve up to the given limit

Examples
• See Receiver Operating Characteristic ROC for an example of using ROC to evaluate the quality of the output of a classifier
• See Receiver Operating Characteristic ROC with cross validation for an example of using ROC to evaluate classifier output quality using crossvalidation
• See Species distribution modeling for an example of using ROC to model species distribution
Zero one loss
Thezerooneloss function computes the sum or the average of the 01 classification loss □0−1 over □samples
By default the function normalizes over the sample To get the sum of the □0−1 setnormalize toFalse
In multilabel classification the zerooneloss scores a subset as one if its labels strictly match the predictions and as a zero if there are any errors By default the function returns the percentage of imperfectly predicted subsets To get the count of such subsets instead set normalize toFalse
If□□is the predicted value of the □th sample and □□is the corresponding true value then the 01 loss □0−1is defined as
□0−1□□□□ 1 □⁄□□
where 1□is the indicator function
 from sklearnmetrics import zerooneloss
ypred 1 2 3 4
ytrue 2 2 3 4

1
Example
• See Recursive feature elimination with crossvalidation for an example of zero one loss usage to perform recursive feature elimination with crossvalidation
Brier score loss
Thebrierscoreloss function computes the Brier score for binary classes Quoting Wikipedia
“The Brier score is a proper score function that measures the accuracy of probabilistic predictions It is applicable to tasks in which predictions must assign probabilities to a set of mutually exclusive discrete outcomes”
This function returns a score of the mean square difference between the actual outcome and the predicted probability of the possible outcome The actual outcome has to be 1 or 0 true or false while the predicted probability of the actual outcome can be a value between 0 and 1
The brier score loss is also between 0 to 1 and the lower the score the mean square difference is smaller the more accurate the prediction is It can be thought of as a measure of the “calibration” of a set of probabilistic predictions
□□1
□□∑
□1□□−□□2
where □is the total number of predictions □□is the predicted probability of the actual outcome □□
Here is a small example of usage of this function

Multilabel ranking metrics
In multilabel learning each sample can have any number of ground truth labels associated with it The goal is to give high scores and better rank to the ground truth labels
Coverage error
Thecoverageerror function computes the average number of labels that have to be included in the final predic tion such that all true labels are predicted This is useful if you want to know how many topscoredlabels you have to predict in average without missing any true one The best value of this metrics is thus the average number of true labels
Note Our implementation’s score is 1 greater than the one given in Tsoumakas et al 2010 This extends it to handle the degenerate case in which an instance has 0 true labels
Formally given a binary indicator matrix of the ground truth labels ∈01samples×labelsand the score associated with each label ∈Rsamples×labels the coverage is defined as
 1
samples samples−1∑
0max
1rank
with rank
≥ Given the rank definition ties in yscores are broken by giving the maximal rank that would have been assigned to all tied values
Here is a small example of usage of this function
```
 import numpy as np
 from sklearnmetrics import coverageerror
ytrue  nparray1 0 0 0 0 1
yscore  nparray075 05 1 1 02 01
coverageerrorytrue yscore
25
```
Label ranking average precision
Thelabelrankingaverageprecisionscore function implements label ranking average precision LRAP This metric is linked to the averageprecisionscore function but is based on the notion of la bel ranking instead of precision and recall

Label ranking average precision LRAP averages over the samples the answer to the following question for each ground truth label what fraction of higherranked labels were true labels This performance measure will be higher if you are able to give better rank to the labels associated with each sample The obtained score is always strictly greater than 0 and the best value is 1 If there is exactly one relevant label per sample label ranking average precision is equivalent to the mean reciprocal rank

Formally given a binary indicator matrix of the ground truth labels ∈01samples×labelsand the score associated with each label ∈Rsamples×labels the average precision is defined as

1samples∑01 0∑1ℒ
rank
whereℒ
1 ≥
rank ≥·computes the cardinality of the set ie the number of elements in the set and · 0is the ℓ0“norm” which computes the number of nonzero elements in a vector

Here is a small example of usage of this function

```
import numpy as np
from sklearnmetrics import labelrankingaverageprecisionscore
ytrue  nparray1 0 0 0 0 1
yscore  nparray075 05 1 1 02 01
labelrankingaverageprecisionscoreytrue yscore
0416
```

Ranking loss

Thelabelrankingloss function computes the ranking loss which averages over the samples the number of label pairs that are incorrectly ordered ie true labels have a lower score than false labels weighted by the inverse of the number of ordered pairs of false and true labels The lowest achievable ranking loss is zero

Formally given a binary indicator matrix of the ground truth labels ∈01samples×labelsand the score associated with each label ∈Rsamples×labels the ranking loss is defined as

1samples∑01 0labels−0
 ≤ 1 0

where·computes the cardinality of the set ie the number of elements in the set and ·0is the ℓ0“norm” which computes the number of nonzero elements in a vector

Here is a small example of usage of this function

```
import numpy as np
from sklearnmetrics import labelrankingloss

Regression metrics
Thesklearnmetrics module implements several loss score and utility functions to measure regression performance Some of those have been enhanced to handle the multioutput case meansquarederror meanabsoluteerror explainedvariancescore andr2score
These functions have an multioutput keyword argument which specifies the way the scores or losses for each individual target should be averaged The default is uniformaverage which specifies a uniformly weighted mean over outputs If an ndarray of shapenoutputs is passed then its entries are interpreted as weights and an according weighted average is returned If multioutput israwvalues is specified then all unaltered individual scores or losses will be returned in an array of shape noutputs
Ther2score andexplainedvariancescore accept an additional value varianceweighted for themultioutput parameter This option leads to a weighting of each individual score by the variance of the corresponding target variable This setting quantifies the globally captured unscaled variance If the target vari ables are of different scale then this score puts more importance on well explaining the higher variance variables multioutputvarianceweighted is the default value for r2score for backward compatibility This will be changed to uniformaverage in the future
Explained variance score
Theexplainedvariancescore computes the explained variance regression score
If□is the estimated target output □the corresponding correct target output and □ □□ is Variance the square of the standard deviation then the explained variance is estimated as follow
□□□□□□□□□ □□□□□□□□□ □□ 1−□ □□□−□
□ □□□
The best possible score is 10 lower values are worse
Here is a small example of usage of the explainedvariancescore function
 from sklearnmetrics import explainedvariancescore
ytrue 3 05 2 7
ypred 25 00 2 8
explainedvariancescoreytrue ypred
0957
ytrue 05 1 1 1 7 6

explainedvariancescoreytrue ypred multioutputrawvalues

array0967 1
explainedvariancescoreytrue ypred multioutput03 07

0990

Max error
Themaxerror function computes the maximum residual error a metric that captures the worst case error between the predicted value and the true value In a perfectly fitted single output regression model maxerror would be0 on the training set and though this would be highly unlikely in the real world this metric shows the extent of error that the model had when it was fitted
If□□is the predicted value of the □th sample and □□is the corresponding true value then the max error is defined as
Max Error □□ □□□□□−□□
Here is a small example of usage of the maxerror function
 from sklearnmetrics import maxerror
ytrue 3 2 7 1
ypred 9 2 7 1
maxerrorytrue ypred
6
Themaxerror does not support multioutput
Mean absolute error
Themeanabsoluteerror function computes mean absolute error a risk metric corresponding to the expected value of the absolute error loss or □1norm loss
If□□is the predicted value of the □th sample and □□is the corresponding true value then the mean absolute error MAE estimated over □samples is defined as
MAE □□ 1
□samples□samples−1∑
□0□□−□□
Here is a small example of usage of the meanabsoluteerror function
 from sklearnmetrics import meanabsoluteerror
ytrue 3 05 2 7
ypred 25 00 2 8
meanabsoluteerrorytrue ypred
05
ytrue 05 1 1 1 7 6
ypred 0 2 1 2 8 5
meanabsoluteerrorytrue ypred
075
meanabsoluteerrorytrue ypred multioutputrawvalues
array05 1
meanabsoluteerrorytrue ypred multioutput03 07

085
Mean squared error
Themeansquarederror function computes mean square error a risk metric corresponding to the expected value of the squared quadratic error or loss

If□□is the predicted value of the □th sample and □□is the corresponding true value then the mean squared error MSE estimated over □samples is defined as

MSE□□ 1
□samples□samples−1∑
□0□□−□□2

Here is a small example of usage of the meansquarederror function

```
 from sklearnmetrics import meansquarederror
ytrue  3 05 2 7
ypred  25 00 2 8
meansquarederrorytrue ypred
0375
ytrue  05 1 1 1 7 6
ypred  0 2 1 2 8 5
meansquarederrorytrue ypred
07083
```

Examples

• See Gradient Boosting regression for an example of mean squared error usage to evaluate gradient boosting regression

Mean squared logarithmic error

Themeansquaredlogerror function computes a risk metric corresponding to the expected value of the squared logarithmic quadratic error or loss

If□□is the predicted value of the □th sample and □□is the corresponding true value then the mean squared logarithmic error MSLE estimated over □samples is defined as

MSLE □□ 1
□samples□samples−1∑
□0log□1 □□−log□1 □□2

Where log□□means the natural logarithm of □ This metric is best to use when targets having exponential growth such as population counts average sales of a commodity over a span of years etc Note that this metric penalizes an underpredicted estimate greater than an overpredicted estimate

Here is a small example of usage of the meansquaredlogerror function

```
 from sklearnmetrics import meansquaredlogerror
ytrue  3 5 25 7
ypred  25 5 4 8
meansquaredlogerrorytrue ypred
0039
ytrue  05 1 1 2 7 6
ypred  05 2 1 25 8 8
meansquaredlogerrorytrue ypred
0044
```

Median absolute error

Themedianabsoluteerror is particularly interesting because it is robust to outliers The loss is calculated by taking the median of all absolute differences between the target and the prediction

If□□is the predicted value of the □th sample and □□is the corresponding true value then the median absolute error
MedAE estimated over □samples is defined as
MedAE □□ median □1−□1 □□−□□
Themedianabsoluteerror does not support multioutput
Here is a small example of usage of the medianabsoluteerror function
```
 from sklearnmetrics import medianabsoluteerror
ytrue  3 05 2 7
ypred  25 00 2 8
medianabsoluteerrorytrue ypred
05
```
R2score the coefficient of determination
Ther2score function computes the coefficient of determination usually denoted as R2
It represents the proportion of variance of y that has been explained by the independent variables in the model It provides an indication of goodness of fit and therefore a measure of how well unseen samples are likely to be predicted by the model through the proportion of explained variance
As such variance is dataset dependent R2may not be meaningfully comparable across different datasets Best possible score is 10 and it can be negative because the model can be arbitrarily worse A constant model that always predicts the expected value of y disregarding the input features would get a R2score of 00
If□□is the predicted value of the □th sample and □□is the corresponding true value for total □samples the estimated R2is defined as
□2□□ 1−∑□
□1□□−□□2
∑□
□1□□−□□2
where □□1
□∑□
□1□□and∑□
□1□□−□□2∑□
□1□2
□
Note thatr2score calculates unadjusted R2without correcting for bias in sample variance of y
Here is a small example of usage of the r2score function
```
 from sklearnmetrics import r2score
ytrue  3 05 2 7
ypred  25 00 2 8
r2scoreytrue ypred
0948
ytrue  05 1 1 1 7 6
ypred  0 2 1 2 8 5
r2scoreytrue ypred multioutputvarianceweighted

ytrue  05 1 1 1 7 6
ypred  0 2 1 2 8 5
r2scoreytrue ypred multioutputuniformaverage

0936
r2scoreytrue ypred multioutputrawvalues

array0965 0908
r2scoreytrue ypred multioutput03 07
```

0925
Example
• See Lasso and Elastic Net for Sparse Signals for an example of R2score usage to evaluate Lasso and Elastic Net on sparse signals
Clustering metrics
Thesklearnmetrics module implements several loss score and utility functions For more information see the Clustering performance evaluation section for instance clustering and Biclustering evaluation for biclustering
Dummy estimators
When doing supervised learning a simple sanity check consists of comparing one's estimator against simple rules of thumbDummyClassifier implements several such simple strategies for classification
•stratified generates random predictions by respecting the training set class distribution
•mostfrequent always predicts the most frequent label in the training set
•prior always predicts the class that maximizes the class prior like mostfrequent and predictproba returns the class prior
•uniform generates predictions uniformly at random
•constant always predicts a constant label that is provided by the user A major motivation of this method is F1scoring when the positive class is in the minority
Note that with all these strategies the predict method completely ignores the input data
To illustrate DummyClassifier first let's create an imbalanced dataset
```
from sklearndatasets import loadiris
from sklearnmodelselection import traintestsplit
iris loadiris
X y irisdata iristarget
yy 1 1
Xtrain Xtest ytrain ytest traintestsplitX y randomstate0
```
Next let's compare the accuracy of SVC andmostfrequent
```
from sklearndummy import DummyClassifier
from sklearnsvm import SVC
clf SVCkernellinear C1fitXtrain ytrain
clfscoreXtest ytest
063
clf DummyClassifierstrategymostfrequent randomstate0
clffitXtrain ytrain
DummyClassifierconstantNone randomstate0 strategymostfrequent
clfscoreXtest ytest
057
```
We see that SVC doesn't do much better than a dummy classifier Now let's change the kernel

clf SVCgammascale kernelrbf C1fitXtrain ytrain
clfscoreXtest ytest
094
We see that the accuracy was boosted to almost 100 A cross validation strategy is recommended for a better estimate of the accuracy if it is not too CPU costly For more information see the Crossvalidation evaluating estimator performance section Moreover if you want to optimize over the parameter space it is highly recommended to use an appropriate methodology see the Tuning the hyperparameters of an estimator section for details
More generally when the accuracy of a classifier is too close to random it probably means that something went wrong features are not helpful a hyperparameter is not correctly tuned the classifier is suffering from class imbalance etc
DummyRegressor also implements four simple rules of thumb for regression
•mean always predicts the mean of the training targets
•median always predicts the median of the training targets
•quantile always predicts a user provided quantile of the training targets
•constant always predicts a constant value that is provided by the user
In all these strategies the predict method completely ignores the input data
334 Model persistence
After training a scikitlearn model it is desirable to have a way to persist the model for future use without having to retrain The following section gives you an example of how to persist a model with pickle We’ll also review a few security and maintainability issues when working with pickle serialization
An alternative to pickling is to export the model to another format using one of the model export tools listed under Related Projects Unlike pickling once exported you cannot recover the full Scikitlearn estimator object but you can deploy the model for prediction usually by using tools supporting open model interchange formats such as ‘ONNX‘ or‘PMML‘
Persistence example
It is possible to save a model in scikitlearn by using Python’s builtin persistence model namely pickle
 from sklearn import svm
 from sklearn import datasets
clf svmSVCgammascale
iris datasetsloadiris
X y irisdata iristarget
clffitX y
SVCC10 cachesize200 classweightNone coef000
decisionfunctionshapeovr degree3 gammascale kernelrbf
maxiter1 probabilityFalse randomstateNone shrinkingTrue
tol0001 verboseFalse
 import pickle
s pickledumpsclf
clf2 pickleloadss
clf2predictX01
array0
y0
0

In the specific case of scikitlearn it may be better to use joblib's replacement of pickle dump load which is more efficient on objects that carry large numpy arrays internally as is often the case for fitted scikitlearn estimators but can only pickle to the disk and not to a string

```
 from joblib import dump load
dumpclf filenamejoblib
```

Later you can load back the pickled model possibly in another Python process with

```
clf  loadfilenamejoblib
```

Notedump andload functions also accept filelike object instead of filenames More information on data persistence with Joblib is available here

Security maintainability limitations

pickle and joblib by extension has some issues regarding maintainability and security Because of this

- Never unpickle untrusted data as it could lead to malicious code being executed upon loading
- While models saved using one version of scikitlearn might load in other versions this is entirely unsupported and inadvisable It should also be kept in mind that operations performed on such data could give different and unexpected results

In order to rebuild a similar model with future versions of scikitlearn additional metadata should be saved along the pickled model

- The training data eg a reference to an immutable snapshot
- The python source code used to generate the model
- The versions of scikitlearn and its dependencies
- The cross validation score obtained on the training data

This should make it possible to check that the crossvalidation score is in the same range as before

Since a model internal representation may be different on two different architectures dumping a model on one architecture and loading it on another architecture is not supported

If you want to know more about these issues and explore other possible serialization methods please refer to this talk by Alex Gaynor

335 Validation curves plotting scores to evaluate models

Every estimator has its advantages and drawbacks Its generalization error can be decomposed in terms of bias variance and noise The bias of an estimator is its average error for different training sets The variance of an estimator indicates how sensitive it is to varying training sets Noise is a property of the data

In the following plot we see a function □□ cos3 2□□and some noisy samples from that function We use three different estimators to fit the function linear regression with polynomial features of degree 1 4 and 15 We see that the first estimator can at best provide only a poor fit to the samples and the true function because it is too simple high bias the second estimator approximates it almost perfectly and the last estimator approximates the training data perfectly but does not fit the true function very well ie it is very sensitive to varying training data high variance

Bias and variance are inherent properties of estimators and we usually have to select learning algorithms and hyper parameters so that both bias and variance are as low as possible see Biasvariance dilemma Another way to reduce

the variance of a model is to use more training data However you should only collect more training data if the true function is too complex to be approximated by an estimator with a lower variance
In the simple onedimensional problem that we have seen in the example it is easy to see whether the estimator suffers from bias or variance However in highdimensional spaces models can become very difficult to visualize For this reason it is often helpful to use the tools described below
Examples
•Underfitting vs Overfitting
•Plotting Validation Curves
•Plotting Learning Curves
Validation curve
To validate a model we need a scoring function see Model evaluation quantifying the quality of predictions for example accuracy for classifiers The proper way of choosing multiple hyperparameters of an estimator are of course grid search or similar methods see Tuning the hyperparameters of an estimator that select the hyperparameter with the maximum score on a validation set or multiple validation sets Note that if we optimized the hyperparameters based on a validation score the validation score is biased and not a good estimate of the generalization any longer To get a proper estimate of the generalization we have to compute the score on another test set
However it is sometimes helpful to plot the influence of a single hyperparameter on the training score and the valida tion score to find out whether the estimator is overfitting or underfitting for some hyperparameter values
The function validationcurve can help in this case
```
 import numpy as np
 from sklearnmodelselection import validationcurve
 from sklearndatasets import loadiris
 from sklearnlinearmodel import Ridge
nprandomseed0
iris  loadiris
X y  irisdata iristarget
indices  nparangeyshape0
nprandomshuffleindices
```

```
X y  Xindices yindices
trainscores validscores  validationcurveRidge X y alpha
 nplogspace7 3 3
 cv5
trainscores
array093 094 092 091 092
093 094 092 091 092
051 052 049 047 049
validscores
array090 084 094 096 093
090 084 094 096 093
046 025 050 049 052
```
If the training score and the validation score are both low the estimator will be underfitting If the training score is high and the validation score is low the estimator is overfitting and otherwise it is working very well A low training score and a high validation score is usually not possible All three cases can be found in the plot below where we vary the parameter of an SVM on the digits dataset

Learning curve

A learning curve shows the validation and training score of an estimator for varying numbers of training samples It is a tool to find out how much we benefit from adding more training data and whether the estimator suffers more from a variance error or a bias error If both the validation score and the training score converge to a value that is too low with increasing size of the training set we will not benefit much from more training data In the following plot you can see an example naive Bayes roughly converges to a low score

We will probably have to use an estimator or a parametrization of the current estimator that can learn more complex concepts ie has a lower bias If the training score is much greater than the validation score for the maximum number of training samples adding more training samples will most likely increase generalization In the following plot you can see that the SVM could benefit from more training examples

We can use the function learningcurve to generate the values that are required to plot such a learning curve number of samples that have been used the average scores on the training sets and the average scores on the validation sets

```
 from sklearnmodelselection import learningcurve
 from sklearnsvm import SVC
```

341 Partial dependence plots
Partial dependence plots PDP show the dependence between the target response1and a set of ‘target’ features
marginalizing over the values of all other features the ‘complement’ features Intuitively we can interpret the partial
dependence as the expected target response as a function of the ‘target’ features
Due to the limits of human perception the size of the target feature set must be small usually one or two thus the
target features are usually chosen among the most important features
The figure below shows four oneway and one twoway partial dependence plots for the California housing dataset
with aGradientBoostingRegressor
Oneway PDPs tell us about the interaction between the target response and the target feature eg linear nonlinear
The upper left plot in the above figure shows the effect of the median income in a district on the median house price
1For classification the target response may be the probability of a class the positive class for binary classification or the decision function

we can clearly see a linear relationship among them Note that PDPs assume that the target features are independent from the complement features and this assumption is often violated in practice
PDPs with two target features show the interactions among the two features For example the twovariable PDP in the above figure shows the dependence of median house price on joint values of house age and average occupants per household We can clearly see an interaction between the two features for an average occupancy greater than two the house price is nearly independent of the house age whereas for values less than 2 there is a strong dependence on age Thesklearninspection module provides a convenience function plotpartialdependence to cre
ate oneway and twoway partial dependence plots In the below example we show how to create a grid of partial dependence plots two oneway PDPs for the features 0and1and a twoway PDP between the two features

```
 from sklearndatasets import makehastie102
 from sklearnensemble import GradientBoostingClassifier
 from sklearninspection import plotpartialdependence
X y  makehastie102randomstate0
clf  GradientBoostingClassifiernestimators100 learningrate10
 maxdepth1 randomstate0fitX y
features  0 1 0 1
plotpartialdependenceclf X features
```

You can access the newly created figure and Axes objects using pltgcf andpltgca
For multiclass classification you need to set the class label for which the PDPs should be created via the target argument

```
 from sklearndatasets import loadiris
iris  loadiris
mcclf  GradientBoostingClassifiernestimators10
 maxdepth1fitirisdata iristarget
features  3 2 3 2
plotpartialdependencemcclf X features target0
```

The same parameter target is used to specify the target in multioutput regression settings
If you need the raw values of the partial dependence function rather than the plots you can use the sklearn inspectionpartialdependence function

```
 from sklearninspection import partialdependence
pdp axes  partialdependenceclf X 0
pdp
array 2466 2466
axes
array1624 1592
```

The values at which the partial dependence should be evaluated are directly generated from X For 2way par tial dependence a 2Dgrid of values is generated The values field returned by sklearninspection partialdependence gives the actual values used in the grid for each target feature They also correspond to the axis of the plots
For each value of the ‘target’ features in the grid the partial dependence function needs to marginalize the predictions of the estimator over all possible values of the ‘complement’ features With the brute method this is done by replacing every target feature value of Xby those in the grid and computing the average prediction
In decision trees this can be evaluated efficiently without reference to the training data recursion method For each grid point a weighted tree traversal is performed if a split node involves a ‘target’ feature the corresponding left or right branch is followed otherwise both branches are followed each branch is weighted by the fraction of

training samples that entered that branch Finally the partial dependence is given by a weighted average of all visited leaves Note that with the recursion methodXis only used to generate the grid not to compute the averaged predictions The averaged predictions will always be computed on the data with which the trees were trained
Examples

35 Dataset transformations
scikitlearn provides a library of transformers which may clean see Preprocessing data reduce see Unsupervised dimensionality reduction expand see Kernel Approximation or generate see Feature extraction feature representations
Like other estimators these are represented by classes with a fit method which learns model parameters eg mean and standard deviation for normalization from a training set and a transform method which applies this transformation model to unseen data fittransform may be more convenient and efficient for modelling and transforming the training data simultaneously
Combining such transformers either in parallel or series is covered in Pipelines and composite estimators Pairwise metrics Affinities and Kernels covers transforming feature spaces into affinity matrices while Transforming the prediction target y considers transformations of the target space eg categorical labels for use in scikitlearn
351 Pipelines and composite estimators
Transformers are usually combined with classifiers regressors or other estimators to build a composite estimator The most common tool is a Pipeline Pipeline is often used in combination with FeatureUnion which concatenates the output of transformers into a composite feature space TransformedTargetRegressor deals with transforming the target ie logtransform y In contrast Pipelines only transform the observed data X
Pipeline chaining estimators
Pipeline can be used to chain multiple estimators into one This is useful as there is often a fixed sequence of steps in processing the data for example feature selection normalization and classification Pipeline serves multiple purposes here
Convenience and encapsulation You only have to call fit andpredict once on your data to fit a whole sequence of estimators
Joint parameter selection You can grid search over parameters of all estimators in the pipeline at once
Safety Pipelines help avoid leaking statistics from your test data into the trained model in crossvalidation by ensuring that the same samples are used to train the transformers and predictors
All estimators in a pipeline except the last one must be transformers ie must have a transform method The last estimator may be any type transformer classifier etc

Usage
Construction
ThePipeline is built using a list of key value pairs where the key is a string containing the name you
want to give this step and value is an estimator object
```
 from sklearnpipeline import Pipeline
 from sklearnsvm import SVC
 from sklearndecomposition import PCA
estimators  reducedim PCA clf SVC
pipe  Pipelineestimators
pipe
PipelinememoryNone
stepsreducedim PCAcopyTrue
clf SVCC10 verboseFalse
```
The utility function makepipeline is a shorthand for constructing pipelines it takes a variable number of estima
tors and returns a pipeline filling in the names automatically
```
 from sklearnpipeline import makepipeline
 from sklearnnaivebayes import MultinomialNB
 from sklearnpreprocessing import Binarizer
makepipelineBinarizer MultinomialNB
PipelinememoryNone
stepsbinarizer BinarizercopyTrue threshold00
multinomialnb MultinomialNBalpha10
classpriorNone
fitpriorTrue
verboseFalse
```
Accessing steps
The estimators of a pipeline are stored as a list in the steps attribute but can be accessed by index or name by
indexing with idx the Pipeline
```
pipesteps0
reducedim PCAcopyTrue iteratedpowerauto ncomponentsNone
randomstateNone svdsolverauto tol00
whitenFalse
pipe0
PCAcopyTrue iteratedpowerauto ncomponentsNone randomstateNone
svdsolverauto tol00 whitenFalse
pipereducedim
PCAcopyTrue
```
Pipeline’snamedsteps attribute allows accessing steps by name with tab completion in interactive environments
```
pipenamedstepsreducedim ispipereducedim
True
```
A subpipeline can also be extracted using the slicing notation commonly used for Python Sequences such as lists or
strings although only a step of 1 is permitted This is convenient for performing only some of the transformations
or their inverse

```
pipe1
PipelinememoryNone stepsreducedim PCAcopyTrue
pipe1
PipelinememoryNone stepsclf SVCC10
```
Nested parameters
Parameters of the estimators in the pipeline can be accessed using the estimatorparameter syntax
```
pipesetparamsclfC10
PipelinememoryNone
stepsreducedim PCAcopyTrue iteratedpowerauto
clf SVCC10 cachesize200 classweightNone
verboseFalse
```
This is particularly important for doing grid searches
```
 from sklearnmodelselection import GridSearchCV
paramgrid  dictreducedimncomponents2 5 10
 clfC01 10 100
gridsearch  GridSearchCVpipe paramgridparamgrid
```
Individual steps may also be replaced as parameters and nonfinal steps may be ignored by setting them to passthrough
```
 from sklearnlinearmodel import LogisticRegression
paramgrid  dictreducedimpassthrough PCA5 PCA10
 clfSVC LogisticRegression
 clfC01 10 100
gridsearch  GridSearchCVpipe paramgridparamgrid
```
The estimators of the pipeline can be retrieved by index
```
pipe0
PCAcopyTrue
```
or by name
```
pipereducedim
PCAcopyTrue
```
Examples
- Pipeline Anova SVM
- Sample pipeline for text feature extraction and evaluation
- Pipelining chaining a PCA and a logistic regression
- Explicit feature map approximation for RBF kernels
- SVMAnova SVM with univariate feature selection
- Selecting dimensionality reduction with Pipeline and GridSearchCV

See also
•Tuning the hyperparameters of an estimator
Notes
Callingfit on the pipeline is the same as calling fit on each estimator in turn transform the input and pass it on to the next step The pipeline has all the methods that the last estimator in the pipeline has ie if the last estimator is a classifier the Pipeline can be used as a classifier If the last estimator is a transformer again so is the pipeline
Caching transformers avoid repeated computation
Fitting transformers may be computationally expensive With its memory parameter set Pipeline will cache each transformer after calling fit This feature is used to avoid computing the fit transformers within a pipeline if the parameters and input data are identical A typical example is the case of a grid search in which the transformers can be fitted only once and reused for each configuration
The parameter memory is needed in order to cache the transformers memory can be either a string containing the directory where to cache the transformers or a joblibMemory object
```
 from tempfile import mkdtemp
 from shutil import rmtree
 from sklearndecomposition import PCA
 from sklearnsvm import SVC
 from sklearnpipeline import Pipeline
estimators  reducedim PCA clf SVC
cachedir  mkdtemp
pipe  Pipelineestimators memorycachedir
pipe
Pipeline
stepsreducedim PCAcopyTrue
clf SVCC10 verboseFalse
 Clear the cache directory when you dont need it anymore
rmtreecachedir
```
Warning Side effect of caching transformers
Using aPipeline without cache enabled it is possible to inspect the original instance such as
```
 from sklearndatasets import loaddigits
digits  loaddigits
pca1  PCA
svm1  SVCgammascale
pipe  Pipelinereducedim pca1 clf svm1
pipefitdigitsdata digitstarget

PipelinememoryNone
stepsreducedim PCA clf SVC
verboseFalse
 The pca instance can be inspected directly
printpca1components
177484909e19  407058917e18
```

Enabling caching triggers a clone of the transformers before fitting Therefore the transformer instance given to the pipeline cannot be inspected directly In following example accessing the PCA instancepca2 will raise an AttributeError sincepca2 will be an unfitted transformer Instead use the attribute namedsteps to inspect estimators within the pipeline

```
cachedir  mkdtemp
pca2  PCA
svm2  SVCgammascale
cachedpipe  Pipelinereducedim pca2 clf svm2
 memorycachedir
cachedpipefitdigitsdata digitstarget

Pipelinememory
stepsreducedim PCA clf SVC
verboseFalse
printcachedpipenamedstepsreducedimcomponents

177484909e19  407058917e18
 Remove the cache directory
rmtreecachedir
```

Examples

•Selecting dimensionality reduction with Pipeline and GridSearchCV

Transforming target in regression

TransformedTargetRegressor transforms the targets ybefore fitting a regression model The predictions are mapped back to the original space via an inverse transform It takes as an argument the regressor that will be used for prediction and the transformer that will be applied to the target variable

```
 import numpy as np
 from sklearndatasets import loadboston
 from sklearncompose import TransformedTargetRegressor
 from sklearnpreprocessing import QuantileTransformer
 from sklearnlinearmodel import LinearRegression
 from sklearnmodelselection import traintestsplit
boston  loadboston
X  bostondata
y  bostontarget
transformer  QuantileTransformeroutputdistributionnormal
regressor  LinearRegression
regr  TransformedTargetRegressorregressorregressor
 transformertransformer
Xtrain Xtest ytrain ytest  traintestsplitX y randomstate0
regrfitXtrain ytrain
TransformedTargetRegressor
printR2 score 02fformatregrscoreXtest ytest
R2 score 067
rawtargetregr  LinearRegressionfitXtrain ytrain
printR2 score 02fformatrawtargetregrscoreXtest ytest
R2 score 064
```

For simple transformations instead of a Transformer object a pair of functions can be passed defining the transfor
mation and its inverse mapping
```
 def funcx
 return nplogx
 def inversefuncx
 return npexpx
```
Subsequently the object is created as
```
regr  TransformedTargetRegressorregressorregressor
 funcfunc
 inversefuncinversefunc
regrfitXtrain ytrain
TransformedTargetRegressor
printR2 score 02fformatregrscoreXtest ytest
```
R2 score 065
By default the provided functions are checked at each fit to be the inverse of each other However it is possible to
bypass this checking by setting checkinverse toFalse
```
 def inversefuncx
 return x
regr  TransformedTargetRegressorregressorregressor
 funcfunc
 inversefuncinversefunc
 checkinverse False
regrfitXtrain ytrain
TransformedTargetRegressor
printR2 score 02fformatregrscoreXtest ytest
```
R2 score 450
Note The transformation can be triggered by setting either transformer or the pair of functions func and
inversefunc However setting both options will raise an error
Examples
•Effect of transforming the targets in regression model
FeatureUnion composite feature spaces
FeatureUnion combines several transformer objects into a new transformer that combines their output A
FeatureUnion takes a list of transformer objects During fitting each of these is fit to the data independently
The transformers are applied in parallel and the feature matrices they output are concatenated sidebyside into a
larger matrix
When you want to apply different transformations to each field of the data see the related class sklearncompose
ColumnTransformer seeuser guide
FeatureUnion serves the same purposes as Pipeline convenience and joint parameter estimation and valida
tion
FeatureUnion andPipeline can be combined to create complex models

AFeatureUnion has no way of checking whether two transformers might produce identical features It only produces a union when the feature sets are disjoint and making sure they are the caller's responsibility
Usage
AFeatureUnion is built using a list of key value pairs where the key is the name you want to give to a given transformation an arbitrary string it only serves as an identifier and value is an estimator object
```
 from sklearnpipeline import FeatureUnion
 from sklearndecomposition import PCA
 from sklearndecomposition import KernelPCA
estimators  linearpca PCA kernelpca KernelPCA
combined  FeatureUnionestimators
combined
FeatureUnionnjobsNone
transformerlistlinearpca PCAcopyTrue
kernelpca KernelPCAalpha10
transformerweightsNone verboseFalse
```
Like pipelines feature unions have a shorthand constructor called makeunion that does not require explicit naming of the components
LikePipeline individual steps may be replaced using setparams and ignored by setting to drop
```
combinedsetparamskernelpcadrop

FeatureUnionnjobsNone
transformerlistlinearpca PCAcopyTrue
kernelpca drop
transformerweightsNone verboseFalse
```
Examples
•Concatenating multiple feature extraction methods
ColumnTransformer for heterogeneous data
Warning ThecomposeColumnTransformer class is experimental and the API is subject to change
Many datasets contain features of different types say text floats and dates where each type of feature requires separate preprocessing or feature extraction steps Often it is easiest to preprocess data before applying scikitlearn methods for example using pandas Processing your data before passing it to scikitlearn might be problematic for one of the following reasons
1 Incorporating statistics from test data into the preprocessors makes crossvalidation scores unreliable known as data leakage for example in the case of scalers or imputing missing values
2 You may want to include the parameters of the preprocessors in a parameter search
TheColumnTransformer helps performing different transformations for different columns of the data within a Pipeline that is safe from data leakage and that can be parametrized ColumnTransformer works on arrays sparse matrices and pandas DataFrames

To each column a different transformation can be applied such as preprocessing or a specific feature extraction method

```
 import pandas as pd
X  pdDataFrame
 city London London Paris Sallisaw
 title His Last Bow How Watson Learned the Trick
 A Moveable Feast The Grapes of Wrath
 expertrating 5 3 4 5
 userrating 4 5 4 3
```

For this data we might want to encode the city column as a categorical variable using preprocessing OneHotEncoder but apply a featureextractiontextCountVectorizer to thetitle column

As we might use multiple feature extraction methods on the same column we give each transformer a unique name say citycategory andtitlebow By default the remaining rating columns are ignored remainderdrop

```
 from sklearncompose import ColumnTransformer
 from sklearnfeatureextractiontext import CountVectorizer
 from sklearnpreprocessing import OneHotEncoder
columntrans  ColumnTransformer
 citycategory OneHotEncoderdtypeintcity
 titlebow CountVectorizer title
 remainderdrop
columntransfitX
ColumnTransformernjobsNone remainderdrop sparsethreshold03

1 0 0 0 0 0 0 1 0 1 0 0 1 1 1 0
0 1 0 0 1 0 0 0 0 0 1 0 0 0 0 0
0 0 1 0 0 1 0 0 0 0 0 1 1 0 0 1
```

In the above example the CountVectorizer expects a 1D array as input and therefore the columns were specified as a string title However preprocessingOneHotEncoder as most of other transformers expects 2D data therefore in that case you need to specify the column as a list of strings city

Apart from a scalar or a single item list the column selection can be specified as a list of multiple items an integer array a slice or a boolean mask Strings can reference columns if the input is a DataFrame integers are always interpreted as the positional columns

We can keep the remaining rating columns by setting remainderpassthrough The values are appended to the end of the transformation

```
columntrans  ColumnTransformer
 citycategory OneHotEncoderdtypeintcity
```

352 Feature extraction
Thesklearnfeatureextraction module can be used to extract features in a format supported by machine learning algorithms from datasets consisting of formats such as text and image
Note Feature extraction is very different from Feature selection the former consists in transforming arbitrary data such as text or images into numerical features usable for machine learning The latter is a machine learning technique

applied on these features
Loading features from dicts
The classDictVectorizer can be used to convert feature arrays represented as lists of standard Python dict
objects to the NumPySciPy representation used by scikitlearn estimators
While not particularly fast to process Python's dict has the advantages of being convenient to use being sparse
absent features need not be stored and storing feature names in addition to values
DictVectorizer implements what is called oneofK or "onehot" coding for categorical aka nominal discrete
features Categorical features are "attributevalue" pairs where the value is restricted to a list of discrete of possibilities
without ordering eg topic identifiers types of objects tags names
In the following "city" is a categorical attribute while "temperature" is a traditional numerical feature
measurements

```
 city Dubai temperature 33
 city London temperature 12
 city San Francisco temperature 18

 from sklearnfeatureextraction import DictVectorizer
vec  DictVectorizer
vecfittransformmeasurementstoarray
array 1 0 0 33
 0 1 0 12
 0 0 1 18
vecgetfeaturenames
cityDubai cityLondon citySan Francisco temperature
```

DictVectorizer is also a useful representation transformation for training sequence classifiers in Natural Lan
guage Processing models that typically work by extracting feature windows around a particular word of interest
For example suppose that we have a first algorithm that extracts Part of Speech PoS tags that we want to use as
complementary tags for training a sequence classifier eg a chunker The following dict could be such a window of
features extracted around the word 'sat' in the sentence 'The cat sat on the mat'

```
poswindow

 word2 the
 pos2 DT
 word1 cat
 pos1 NN
 word1 on
 pos1 PP

  in a real application one would extract many such dictionaries
```

This description can be vectorized into a sparse twodimensional matrix suitable for feeding into a classifier maybe
after being piped into a textTfidfTransformer for normalization

```
vec  DictVectorizer
posvectorized  vecfittransformposwindow
```

posvectorized
1x6 sparse matrix of type numpyfloat64
with 6 stored elements in Compressed Sparse format
posvectorizedtoarray
array1 1 1 1 1 1
vecgetfeaturenames
pos1PP pos1NN pos2DT word1on word1cat word2the
As you can imagine if one extracts such a context around each individual word of a corpus of documents the resulting matrix will be very wide many onehotfeatures with most of them being valued to zero most of the time So as to make the resulting data structure able to fit in memory the DictVectorizer class uses a scipysparse matrix by default instead of a numpyndarray

Feature hashing

The classFeatureHasher is a highspeed lowmemory vectorizer that uses a technique known as feature hashing or the “hashing trick” Instead of building a hash table of the features encountered in training as the vectorizers do instances of FeatureHasher apply a hash function to the features to determine their column index in sample matrices directly The result is increased speed and reduced memory usage at the expense of inspectability the hasher does not remember what the input features looked like and has no inversetransform method

Since the hash function might cause collisions between unrelated features a signed hash function is used and the sign of the hash value determines the sign of the value stored in the output matrix for a feature This way collisions are likely to cancel out rather than accumulate error and the expected mean of any output feature’s value is zero This mechanism is enabled by default with alternatesignTrue and is particularly useful for small hash table sizes nfeatures 10000 For large hash table sizes it can be disabled to allow the output to be passed to estimators like sklearnnaivebayesMultinomialNB orsklearnfeatureselectionchi2 feature selectors that expect nonnegative inputs

FeatureHasher accepts either mappings like Python’s dict and its variants in the collections module feature value pairs or strings depending on the constructor parameter inputtype Mapping are treated as lists offeature value pairs while single strings have an implicit value of 1 so feat1 feat2 feat3 is interpreted as feat1 1 feat2 1 feat3 1 If a single feature occurs multiple times in a sample the associated values will be summed so feat 2 andfeat 35 become feat 55 The output from FeatureHasher is always a scipysparse matrix in the CSR format

Feature hashing can be employed in document classification but unlike textCountVectorizer FeatureHasher does not do word splitting or any other preprocessing except UnicodetoUTF8 encoding see Vectorizing a large text corpus with the hashing trick below for a combined tokenizerhasher

As an example consider a wordlevel natural language processing task that needs features extracted from token partofspeech pairs One could use a Python generator function to extract features

```
deftokenfeaturestoken partofspeech
iftokenisdigit
yieldnumeric
else
yieldtokenformattokenlower
yieldtokenpos formattoken partofspeech
iftoken0isupper
yielduppercaseinitial
iftokenisupper
yieldalluppercase
yieldposformatpartofspeech
```

Then therawX to be fed to FeatureHashertransform can be constructed using

rawX tokenfeaturestok postaggertok fortokincorpus
and fed to a hasher with
hasher FeatureHasherinputtypestring
X hashertransformrawX
to get ascipysparse matrixX
Note the use of a generator comprehension which introduces laziness into the feature extraction tokens are only processed on demand from the hasher
Implementation details
FeatureHasher uses the signed 32bit variant of MurmurHash3 As a result and because of limitations in scipy sparse the maximum number of features supported is currently 231−1
The original formulation of the hashing trick by Weinberger et al used two separate hash functions *h*and□to determine the column index and sign of a feature respectively The present implementation works under the assumption that the sign bit of MurmurHash3 is independent of its other bits
Since a simple modulo is used to transform the hash function to a column index it is advisable to use a power of two as thenfeatures parameter otherwise the features will not be mapped evenly to the columns

Text feature extraction
The Bag of Words representation
Text Analysis is a major application field for machine learning algorithms However the raw data a sequence of symbols cannot be fed directly to the algorithms themselves as most of them expect numerical feature vectors with a fixed size rather than the raw text documents with variable length
In order to address this scikitlearn provides utilities for the most common ways to extract numerical features from text content namely
•tokenizing strings and giving an integer id for each possible token for instance by using whitespaces and punctuation as token separators
•counting the occurrences of tokens in each document
•normalizing and weighting with diminishing importance tokens that occur in the majority of samples documents
In this scheme features and samples are defined as follows
• each individual token occurrence frequency normalized or not is treated as a feature
• the vector of all the token frequencies for a given document is considered a multivariate sample

A corpus of documents can thus be represented by a matrix with one row per document and one column per token eg word occurring in the corpus
We call vectorization the general process of turning a collection of text documents into numerical feature vectors This specific strategy tokenization counting and normalization is called the Bag of Words or “Bag of ngrams” representation Documents are described by word occurrences while completely ignoring the relative position information of the words in the document
Sparsity
As most documents will typically use a very small subset of the words used in the corpus the resulting matrix will have many feature values that are zeros typically more than 99 of them
For instance a collection of 10000 short text documents such as emails will use a vocabulary with a size in the order of 100000 unique words in total while each document will use 100 to 1000 unique words individually
In order to be able to store such a matrix in memory but also to speed up algebraic operations matrix vector implementations will typically use a sparse representation such as the implementations available in the scipysparse package
Common Vectorizer usage
CountVectorizer implements both tokenization and occurrence counting in a single class
```
 from sklearnfeatureextractiontext import CountVectorizer
```
This model has many parameters however the default values are quite reasonable please see the reference documentation for the details
```
vectorizer  CountVectorizer

Using stop words
Stop words are words like “and” “the” “him” which are presumed to be uninformative in representing the content of a text and which may be removed to avoid them being construed as signal for prediction Sometimes however similar words are useful for prediction such as in classifying writing style or personality
There are several known issues in our provided ‘english’ stop word list See NQY18
Please take care in choosing a stop word list Popular stop word lists may include words that are highly informative to some tasks such as computer
You should also make sure that the stop word list has had the same preprocessing and tokenization applied as the one used in the vectorizer The word we’ve is split into weandveby CountVectorizer’s default tokenizer so if we’ve is in stopwords but veis not vewill be retained from we’ve in transformed text Our vectorizers will try to identify and warn about some kinds of inconsistencies
References
Tf–idf term weighting
In a large text corpus some words will be very present eg “the” “a” “is” in English hence carrying very little meaningful information about the actual contents of the document If we were to feed the direct count data directly to a classifier those very frequent terms would shadow the frequencies of rarer yet more interesting terms
In order to reweight the count features into floating point values suitable for usage by a classifier it is very common to use the tf–idf transform
Tf means termfrequency while tf–idf means termfrequency times inverse documentfrequency tfidftd tftd×idft
Using the TfidfTransformer ’s default settings TfidfTransformernorml2 useidfTrue smoothidfTrue sublineartfFalse the term frequency the number of times a term occurs in a given document is multiplied with idf component which is computed as
idf log1
1df 1
where is the total number of documents in the document set and df is the number of documents in the document set that contain term The resulting tfidf vectors are then normalized by the Euclidean norm
2√
12222
This was originally a term weighting scheme developed for information retrieval as a ranking function for search engines results that has also found good use in document classification and clustering
The following sections contain further explanations and examples that illustrate how the tfidfs are computed exactly and how the tfidfs computed in scikitlearn’s TfidfTransformer andTfidfVectorizer differ slightly from the standard textbook notation that defines the idf as
idf log
1df
In theTfidfTransformer andTfidfVectorizer withsmoothidfFalse the “1” count is added to the idf instead of the idf’s denominator
idf log
df 1

This normalization is implemented by the TfidfTransformer class
```
 from sklearnfeatureextractiontext import TfidfTransformer
transformer  TfidfTransformersmoothidf False
transformer
TfidfTransformernorml2 smoothidfFalse sublineartfFalse
useidfTrue
```
Again please see the reference documentation for the details on all the parameters
Let’s take an example with the following counts The first term is present 100 of the time hence not very interesting
The two other features only in less than 50 of the time hence probably more representative of the content of the
documents
```
counts  3 0 1
 2 0 0
 3 0 0
 4 0 0
 3 2 0
 3 0 2

tfidf  transformerfittransformcounts
tfidf
6x3 sparse matrix of type  numpyfloat64
with 9 stored elements in Compressed Sparse  format
tfidftoarray
array081940995 0  057320793
1  0  0
1  0  0
1  0  0
047330339 088089948 0
058149261 0  081355169
```
Each row is normalized to have unit Euclidean norm
□□□□□ □
□2□√
□12□22⋯□□2
For example we can compute the tfidf of the first term in the first document in the counts array as follows
□ 6
df□term1 6
idf□term1 log□
df□ 1 log1 1 1
tfidf term1tf×idf 3×1 3
Now if we repeat this computation for the remaining 2 terms in the document we get
tfidf term2 0×log6 1 1 0
tfidf term3 1×log6 2 1≈20986
and the vector of raw tfidfs
tfidf raw 3020986
Then applying the Euclidean L2 norm we obtain the following tfidfs for document 1
3020986√
3202209862 081900573

scikitlearn user guide Release 0213
Furthermore the default parameter smoothidfTrue adds “1” to the numerator and denominator as if an extra document was seen containing every term in the collection exactly once which prevents zero divisions
idf log1
1df 1
Using this modification the tfidf of the third term in document 1 changes to 18473
tfidf term3 1×log73 1≈18473
And the L2normalized tfidf changes to
3018473√

The weights of each feature computed by the fit method call are stored in a model attribute
transformeridf
array1 225 184
As tf–idf is very often used for text features there is also another class called TfidfVectorizer that combines all the options of CountVectorizer andTfidfTransformer in a single model
from sklearnfeatureextractiontext import TfidfVectorizer
vectorizer TfidfVectorizer
vectorizerfittransformcorpus

4x9 sparse matrix of type numpyfloat64
with 19 stored elements in Compressed Sparse format
While the tf–idf normalization is often very useful there might be cases where the binary occurrence markers might offer better features This can be achieved by using the binary parameter of CountVectorizer In particular some estimators such as Bernoulli Naive Bayes explicitly model discrete boolean random variables Also very short texts are likely to have noisy tf–idf values while the binary occurrence info is more stable
As usual the best way to adjust the feature extraction parameters is to use a crossvalidated grid search for instance by pipelining the feature extractor with a classifier
•Sample pipeline for text feature extraction and evaluation
Decoding text files
Text is made of characters but files are made of bytes These bytes represent characters according to some encoding To work with text files in Python their bytes must be decoded to a character set called Unicode Common encodings are ASCII Latin1 Western Europe KOI8R Russian and the universal encodings UTF8 and UTF16 Many others exist
Note An encoding can also be called a ‘character set’ but this term is less accurate several encodings can exist for a single character set

The text feature extractors in scikitlearn know how to decode text files but only if you tell them what encoding the files are in The CountVectorizer takes anencoding parameter for this purpose For modern text files the correct encoding is probably UTF8 which is therefore the default encodingutf8
If the text you are loading is not actually encoded with UTF8 however you will get a UnicodeDecodeError
The vectorizers can be told to be silent about decoding errors by setting the decodeerror parameter to either ignore orreplace See the documentation for the Python function bytesdecode for more details type helpbytesdecode at the Python prompt
If you are having trouble decoding text here are some things to try
• Find out what the actual encoding of the text is The file might come with a header or README that tells you the encoding or there might be some standard encoding you can assume based on where the text comes from
• You may be able to find out what kind of encoding it is in general using the UNIX command file The Python chardet module comes with a script called chardetectpy that will guess the specific encoding though you cannot rely on its guess being correct
• You could try UTF8 and disregard the errors You can decode byte strings with bytes decodeerrorsreplace to replace all decoding errors with a meaningless character or set decodeerrorreplace in the vectorizer This may damage the usefulness of your features
• Real text may come from a variety of sources that may have used different encodings or even be sloppily decoded in a different encoding than the one it was encoded with This is common in text retrieved from the Web The Python package ftfy can automatically sort out some classes of decoding errors so you could try decoding the unknown text as latin1 and then using ftfy to fix errors
• If the text is in a mishmash of encodings that is simply too hard to sort out which is the case for the 20 Newsgroups dataset you can fall back on a simple singlebyte encoding such as latin1 Some text may display incorrectly but at least the same sequence of bytes will always represent the same feature
For example the following snippet uses chardet not shipped with scikitlearn must be installed separately to figure out the encoding of three texts It then vectorizes the texts and prints the learned vocabulary The output is not shown here
```
 import chardet
text1  bSei mir gegr xc3xbcxc3x9f t mein Sauerkraut
text2  bholdselig sind deine Ger xfcche
text3  b xffxfe Ax00ux00fx00 x00 Fx00lx00xfcx00 gx00ex00lx00nx00
‹→x00dx00ex00sx00 x00 Gx00ex00sx00ax00nx00gx00ex00sx00x00

‹→x00fx00ox00rx00tx00
decoded  xdecodechardetdetectxencoding
 for xintext1 text2 text3
v  CountVectorizerfitdecodedvocabulary
 for terminv printv
```
Depending on the version of chardet it might get the first one wrong
For an introduction to Unicode and character encodings in general see Joel Spolsky’s Absolute Minimum Every Software Developer Must Know About Unicode
Applications and examples
The bag of words representation is quite simplistic but surprisingly useful in practice
In particular in a supervised setting it can be successfully combined with fast and scalable linear models to train document classifiers for instance

•Classification of text documents using sparse features
In an unsupervised setting it can be used to group similar documents together by applying clustering algorithms such asKmeans
•Clustering text documents using kmeans
Finally it is possible to discover the main topics of a corpus by relaxing the hard assignment constraint of clustering for instance by using Nonnegative matrix factorization NMF or NNMF
•Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet Allocation
Limitations of the Bag of Words representation
A collection of unigrams what bag of words is cannot capture phrases and multiword expressions effectively disregarding any word order dependence Additionally the bag of words model doesn't account for potential misspellings or word derivations
Ngrams to the rescue Instead of building a simple collection of unigrams n1 one might prefer a collection of bigrams n2 where occurrences of pairs of consecutive words are counted
One might alternatively consider a collection of character ngrams a representation resilient against misspellings and derivations
For example let's say we're dealing with a corpus of two documents words wprds The second document contains a misspelling of the word 'words' A simple bag of words representation would consider these two as very distinct documents differing in both of the two possible features A character 2gram representation however would find the documents matching in 4 out of 8 features which may help the preferred classifier decide better
```
ngramvectorizer  CountVectorizeranalyzercharwb ngramrange2 2
counts  ngramvectorizerfittransformwords wprds
ngramvectorizergetfeaturenames
  w ds or pr rd s  wo wp
True
countstoarrayastypeint
array1 1 1 0 1 1 1 0
1 1 0 1 1 1 0 1
```
In the above example charwb analyzer is used which creates ngrams only from characters inside word boundaries padded with space on each side The char analyzer alternatively creates ngrams that span across words
```
ngramvectorizer  CountVectorizeranalyzercharwb ngramrange5 5
ngramvectorizerfittransformjumpy fox

1x4 sparse matrix of type  numpyint64
with 4 stored elements in Compressed Sparse  format
ngramvectorizergetfeaturenames
  fox   jump jumpy umpy
True
ngramvectorizer  CountVectorizeranalyzerchar ngramrange5 5
ngramvectorizerfittransformjumpy fox

1x5 sparse matrix of type  numpyint64
with 5 stored elements in Compressed Sparse  format
ngramvectorizergetfeaturenames
 jumpy mpy f py fo umpy  y fox
True
```

The word boundariesaware variant charwb is especially interesting for languages that use whitespaces for word separation as it generates significantly less noisy features than the raw char variant in that case For such languages it can increase both the predictive accuracy and convergence speed of classifiers trained using such features while retaining the robustness with regards to misspellings and word derivations

While some local positioning information can be preserved by extracting ngrams instead of individual words bag of words and bag of ngrams destroy most of the inner structure of the document and hence most of the meaning carried by that internal structure

In order to address the wider task of Natural Language Understanding the local structure of sentences and paragraphs should thus be taken into account Many such models will thus be casted as “Structured output” problems which are currently outside of the scope of scikitlearn

Vectorizing a large text corpus with the hashing trick

The above vectorization scheme is simple but the fact that it holds an in memory mapping from the string tokens to the integer feature indices thevocabulary attribute causes several problems when dealing with large datasets

• the larger the corpus the larger the vocabulary will grow and hence the memory use too
• fitting requires the allocation of intermediate data structures of size proportional to that of the original dataset
• building the wordmapping requires a full pass over the dataset hence it is not possible to fit text classifiers in a strictly online manner
• pickling and unpickling vectorizers with a large vocabulary can be very slow typically much slower than pickling unpickling flat data structures such as a NumPy array of the same size
• it is not easily possible to split the vectorization work into concurrent sub tasks as the vocabulary attribute would have to be a shared state with a fine grained synchronization barrier the mapping from token string to feature index is dependent on ordering of the first occurrence of each token hence would have to be shared potentially harming the concurrent workers’ performance to the point of making them slower than the sequential variant

It is possible to overcome those limitations by combining the “hashing trick” Feature hashing implemented by the sklearnfeatureextractionFeatureHasher class and the text preprocessing and tokenization features of theCountVectorizer

This combination is implementing in HashingVectorizer a transformer class that is mostly API compatible with CountVectorizer HashingVectorizer is stateless meaning that you don’t have to call fit on it

```
 from sklearnfeatureextractiontext import HashingVectorizer
hv  HashingVectorizernfeatures10
hvtransformcorpus

4x10 sparse matrix of type  numpyfloat64
with 16 stored elements in Compressed Sparse  format
```

You can see that 16 nonzero feature tokens were extracted in the vector output this is less than the 19 nonzeros extracted previously by the CountVectorizer on the same toy corpus The discrepancy comes from hash function collisions because of the low value of the nfeatures parameter

In a real world setting the nfeatures parameter can be left to its default value of 220roughly one million possible features If memory or downstream models size is an issue selecting a lower value such as 218might help without introducing too many additional collisions on typical text classification tasks

Note that the dimensionality does not affect the CPU training time of algorithms which operate on CSR matrices LinearSVCdualTrue Perceptron SGDClassifier PassiveAggressive but it does for algo
rithms that work with CSC matrices LinearSVCdualFalse Lasso etc
Let’s try again with the default setting
hv HashingVectorizer
hvtransformcorpus

4x1048576 sparse matrix of type numpyfloat64
with 19 stored elements in Compressed Sparse format
We no longer get the collisions but this comes at the expense of a much larger dimensionality of the output space Of course other terms than the 19 used here might still collide with each other
TheHashingVectorizer also comes with the following limitations
• it is not possible to invert the model no inversetransform method nor to access the original string representation of the features because of the oneway nature of the hash function that performs the mapping
• it does not provide IDF weighting as that would introduce statefulness in the model A TfidfTransformer can be appended to it in a pipeline if required
Performing outofcore scaling with HashingVectorizer
An interesting development of using a HashingVectorizer is the ability to perform outofcore scaling This means that we can learn from data that does not fit into the computer’s main memory
A strategy to implement outofcore scaling is to stream data to the estimator in minibatches Each minibatch is vectorized using HashingVectorizer so as to guarantee that the input space of the estimator has always the same dimensionality The amount of memory used at any time is thus bounded by the size of a minibatch Although there is no limit to the amount of data that can be ingested using such an approach from a practical point of view the learning time is often limited by the CPU time one wants to spend on the task
For a fullfledged example of outofcore scaling in a text classification task see Outofcore classification of text documents
Customizing the vectorizer classes
It is possible to customize the behavior by passing a callable to the vectorizer constructor
 def mytokenizers
 return ssplit

vectorizer CountVectorizertokenizermytokenizer
vectorizerbuildanalyzeruSome punctuation
 some punctuation
True
In particular we name
•preprocessor a callable that takes an entire document as input as a single string and returns a possibly transformed version of the document still as an entire string This can be used to remove HTML tags lowercase the entire document etc
•tokenizer a callable that takes the output from the preprocessor and splits it into tokens then returns a list of these

•analyzer a callable that replaces the preprocessor and tokenizer The default analyzers all call the prepro
cessor and tokenizer but custom analyzers will skip this Ngram extraction and stop word filtering take place
at the analyzer level so a custom analyzer may have to reproduce these steps
Lucene users might recognize these names but be aware that scikitlearn concepts may not map onetoone onto
Lucene concepts
To make the preprocessor tokenizer and analyzers aware of the model parameters it is possible to derive from the class
and override the buildpreprocessor buildtokenizer andbuildanalyzer factory methods instead
of passing custom functions
Some tips and tricks
• If documents are pretokenized by an external package then store them in files or strings with the tokens
separated by whitespace and pass analyzerstrsplit
• Fancy tokenlevel analysis such as stemming lemmatizing compound splitting filtering based on partof
speech etc are not included in the scikitlearn codebase but can be added by customizing either the tokenizer
or the analyzer Here’s a CountVectorizer with a tokenizer and lemmatizer using NLTK
```
 from nltk import wordtokenize
 from nltkstem import WordNetLemmatizer
 class LemmaTokenizer object
 def initself
 selfwnl  WordNetLemmatizer
 def callself doc
 return selfwnllemmatizet fortinwordtokenizedoc

vect  CountVectorizertokenizerLemmaTokenizer
```
Note that this will not filter out punctuation
The following example will for instance transform some British spelling to American spelling
```
 import re
 def tobritishtokens
 for tintokens
 t  resubrour r1or t
 t  resubrbtre r1er t
 t  resubriyseingation r1z2 t
 t  resubrogue og t
 yield t

 class CustomVectorizer CountVectorizer
 def buildtokenizerself
 tokenize  superbuildtokenizer
 return lambda doc listtobritishtokenizedoc

printCustomVectorizerbuildanalyzerucolor colour
color color
```
for other styles of preprocessing examples include stemming lemmatization or normalizing numerical tokens
with the latter illustrated in
–Biclustering documents with the Spectral Coclustering algorithm
Customizing the vectorizer can also be useful when handling Asian languages that do not use an explicit word separator
such as whitespace

Image feature extraction
Patch extraction
Theextractpatches2d function extracts patches from an image stored as a twodimensional array or threedimensional with color information along the third axis For rebuilding an image from all its patches use reconstructfrompatches2d For example let use generate a 4x4 pixel picture with 3 color channels eg in RGB format

```
 import numpy as np
 from sklearnfeatureextraction import image
oneimage  nparange4 43reshape4 4 3
oneimage  0  R channel of a fake RGB picture
array 0 3 6 9
12 15 18 21
24 27 30 33
36 39 42 45
patches  imageextractpatches2doneimage 2 2 maxpatches2
 randomstate0
patchesshape
2 2 2 3
patches   0
array 0 3
12 15
15 18
27 30
patches  imageextractpatches2doneimage 2 2
patchesshape
9 2 2 3
patches4   0
array15 18
27 30
```

Let us now try to reconstruct the original image from the patches by averaging on overlapping areas

```
reconstructed  imagereconstructfrompatches2dpatches 4 4 3
nptestingassertarrayequaloneimage reconstructed
```

ThePatchExtractor class works in the same way as extractpatches2d only it supports multiple images as input It is implemented as an estimator so it can be used in pipelines See

```
fiveimages  nparange5 443reshape5 4 4 3
patches  imagePatchExtractor2 2transformfiveimages
patchesshape
45 2 2 3
```

Connectivity graph of an image
Several estimators in the scikitlearn can use connectivity information between features or samples For instance Ward clustering Hierarchical clustering can cluster together only neighboring pixels of an image thus forming contiguous patches
For this purpose the estimators use a ‘connectivity’ matrix giving which samples are connected

The function imgtograph returns such a matrix from a 2D or 3D image Similarly gridtograph build a connectivity matrix for images given the shape of these image

These matrices can be used to impose connectivity in estimators that use connectivity information such as Ward clustering Hierarchical clustering but also to build precomputed kernels or similarity matrices

Note Examples

•A demo of structured Ward hierarchical clustering on an image of coins

•Spectral clustering for image segmentation

•Feature agglomeration vs univariate selection

353 Preprocessing data

Thesklearnpreprocessing package provides several common utility functions and transformer classes to change raw feature vectors into a representation that is more suitable for the downstream estimators

In general learning algorithms benefit from standardization of the data set If some outliers are present in the set robust scalers or transformers are more appropriate The behaviors of the different scalers transformers and normalizers on a dataset containing marginal outliers is highlighted in Compare the effect of different scalers on data with outliers

Standardization or mean removal and variance scaling

Standardization of datasets is a common requirement for many machine learning estimators implemented in scikitlearn they might behave badly if the individual features do not more or less look like standard normally dis tributed data Gaussian with zero mean and unit variance

In practice we often ignore the shape of the distribution and just transform the data to center it by removing the mean value of each feature then scale it by dividing nonconstant features by their standard deviation

For instance many elements used in the objective function of a learning algorithm such as the RBF kernel of Support Vector Machines or the l1 and l2 regularizers of linear models assume that all features are centered around zero and have variance in the same order If a feature has a variance that is orders of magnitude larger than others it might dominate the objective function and make the estimator unable to learn from other features correctly as expected

The function scale provides a quick and easy way to perform this operation on a single arraylike dataset

```
 from sklearn import preprocessing
 import numpy as np
```

scikitlearn user guide Release 0213

 122 0 026
122 122 106
The scaler instance can then be used on new data to transform it the same way it did on the training set
Xtest 1 1 0
scalertransformXtest
array244 122 026
It is possible to disable either centering or scaling by either passing withmeanFalse orwithstdFalse to
the constructor of StandardScaler
Scaling features to a range
An alternative standardization is scaling features to lie between a given minimum and maximum value often between
zero and one or so that the maximum absolute value of each feature is scaled to unit size This can be achieved using
MinMaxScaler orMaxAbsScaler respectively
The motivation to use this scaling include robustness to very small standard deviations of features and preserving zero
entries in sparse data
Here is an example to scale a toy data matrix to the 0 1 range

```
Xtrain  nparray 1 1 2
  2 0 0
  0 1 1

minmaxscaler  preprocessingMinMaxScaler
Xtrainminmax  minmaxscalerfittransformXtrain
Xtrainminmax
array05  0  1
1  05  033333333
0  1  0
```
The same instance of the transformer can then be applied to some new test data unseen during the fit call the same scaling and shifting operations will be applied to be consistent with the transformation performed on the train data
```
Xtest  nparray3 1 4
Xtestminmax  minmaxscalertransformXtest
Xtestminmax
array15  0  166666667
```
It is possible to introspect the scaler attributes to find about the exact nature of the transformation learned on the training data
```
minmaxscalerscale
array05  05  033
minmaxscalermin
array0  05  033
```
IfMinMaxScaler is given an explicit featurerangemin max the full formula is
```
Xstd  X  Xminaxis0  Xmaxaxis0  Xminaxis0
Xscaled  Xstd max  min  min
```
MaxAbsScaler works in a very similar fashion but scales in a way that the training data lies within the range 1 1by dividing through the largest maximum value in each feature It is meant for data that is already centered at zero or sparse data

Here is how to use the toy data from the previous example with this scaler
```
Xtrain  nparray 1 1 2
  2 0 0
  0 1 1

maxabsscaler  preprocessingMaxAbsScaler
Xtrainmaxabs  maxabsscalerfittransformXtrain
Xtrainmaxabs  doctest NORMALIZEWHITESPACE
array 05 1  1
 1  0  0
 0  1  05
Xtest  nparray 3 1 4
Xtestmaxabs  maxabsscalertransformXtest
Xtestmaxabs
array15 1  2
maxabsscalerscale
array2 1 2
```

As withscale the module further provides convenience functions minmaxscale andmaxabsscale if you don't want to create an object

Scaling sparse data

Centering sparse data would destroy the sparseness structure in the data and thus rarely is a sensible thing to do However it can make sense to scale sparse inputs especially if features are on different scales MaxAbsScaler andmaxabsscale were specifically designed for scaling sparse data and are the recommended way to go about this However scale andStandardScaler can accept scipysparse matrices as input as long aswithmeanFalse is explicitly passed to the constructor Otherwise a ValueError will be raised as silently centering would break the sparsity and would often crash the execution by allocating excessive amounts of memory unintentionally RobustScaler cannot be fitted to sparse inputs but you can use the transform method on sparse inputs

Note that the scalers accept both Compressed Sparse Rows and Compressed Sparse Columns format see scipy sparsecsrmatrix andscipysparsecscmatrix Any other sparse input will be converted to the Compressed Sparse Rows representation To avoid unnecessary memory copies it is recommended to choose the CSR or CSC representation upstream

Finally if the centered data is expected to be small enough explicitly converting the input to an array using the toarray method of sparse matrices is another option

Scaling data with outliers

If your data contains many outliers scaling using the mean and variance of the data is likely to not work very well In these cases you can use robustscale andRobustScaler as dropin replacements instead They use more robust estimates for the center and range of your data

References

Further discussion on the importance of centering and scaling data is available on this FAQ Should I normal izestandardizerescale the data

Scaling vs Whitening

It is sometimes not enough to center and scale the features independently since a downstream model can further make some assumption on the linear independence of the features

To address this issue you can use sklearndecompositionPCA withwhitenTrue to further remove the linear correlation across features

Scaling a 1D array

All above functions ie scale minmaxscale maxabsscale androbustscale accept 1D array which can be useful in some specific case

Centering kernel matrices
If you have a kernel matrix of a kernel that computes a dot product in a feature space defined by function *h* a KernelCenterer can transform the kernel matrix so that it contains inner products in the feature space defined by *h* followed by removal of the mean in that space
Nonlinear transformation
Two types of transformations are available quantile transforms and power transforms Both quantile and power transforms are based on monotonic transformations of the features and thus preserve the rank of the values along each feature
Quantile transforms put all features into the same desired distribution based on the formula −1 where is the cumulative distribution function of the feature and −1the quantile function of the desired output distribution This formula is using the two following facts i if is a random variable with a continuous cumulative distribution function then is uniformly distributed on 01 ii if is a random variable with uniform distribution on 01then −1 has distribution By performing a rank transformation a quantile transform smooths out unusual distributions and is less influenced by outliers than scaling methods It does however distort correlations and distances within and across features
Power transforms are a family of parametric transformations that aim to map data from any distribution to as close to a Gaussian distribution
Mapping to a Uniform distribution
QuantileTransformer andquantiletransform provide a nonparametric transformation to map the data to a uniform distribution with values between 0 and 1

```
 from sklearndatasets import loadiris
 from sklearnmodelselection import traintestsplit
iris  loadiris
X y  irisdata iristarget
Xtrain Xtest ytrain ytest  traintestsplitX y randomstate0

This can be confirmed on a independent testing set with similar remarks

```
nppercentileXtest 0 0 25 50 75 100

array 44  5125 575  6175 73
nppercentileXtesttrans 0 0 25 50 75 100

array 001 025 046 060  094
```

Mapping to a Gaussian distribution

In many modeling scenarios normality of the features in a dataset is desirable Power transforms are a family of parametric monotonic transformations that aim to map data from any distribution to as close to a Gaussian distribution as possible in order to stabilize variance and minimize skewness

PowerTransformer currently provides two such power transformations the YeoJohnson transform and the Box Cox transform

The YeoJohnson transform is given by

□□
□ ⎧
⎪⎪⎪⎪⎪⎪⎪⎨
⎪⎪⎪⎪⎪⎪⎪⎩□□ 1□−1□ if□ 0 □□≥0
ln □□ 1 if□ 0 □□≥0
−−□□ 12−□−12−□if□ 2 □□0
−ln−□□ 1 if□ 2 □□0

while the BoxCox transform is given by

□□
□ ⎧
⎪⎪⎨
⎪⎪⎩□□
□−1
□if□ 0
ln □□if□ 0

BoxCox can only be applied to strictly positive data In both methods the transformation is parameterized by □ which is determined through maximum likelihood estimation Here is an example of using BoxCox to map samples drawn from a lognormal distribution to a normal distribution

```
pt  preprocessingPowerTransformermethodboxcox standardize False
Xlognormal  nprandomRandomState616lognormalsize3 3
Xlognormal
array128 118 084
094 160 038
135 021 109
ptfittransformXlognormal
array 049 017 015
005 058 057
 069 084 010
```

While the above example sets the standardize option toFalse PowerTransformer will apply zeromean unitvariance normalization to the transformed output by default

Below are examples of BoxCox and YeoJohnson applied to various probability distributions Note that when applied to certain distributions the power transforms achieve very Gaussianlike results but with others they are ineffective This highlights the importance of visualizing the data before and after transformation

It is also possible to map data to a normal distribution using QuantileTransformer by setting outputdistributionnormal Using the earlier example with the iris dataset

```
quantiletransformer  preprocessingQuantileTransformer
 outputdistributionnormal randomstate0
Xtrans  quantiletransformerfittransformX
quantiletransformerquantiles
array43 2  1  01
44 22 11 01
44 22 12 01
```

scikitlearn user guide Release 0213
604 Chapter 3 User Guide

77 41 67 25
77 42 67 25
79 44 69 25
Thus the median of the input becomes the mean of the output centered at 0 The normal output is clipped so that the input’s minimum and maximum — corresponding to the 1e7 and 1 1e7 quantiles respectively — do not become infinite under the transformation

Normalization

Normalization is the process of scaling individual samples to have unit norm This process can be useful if you plan to use a quadratic form such as the dotproduct or any other kernel to quantify the similarity of any pair of samples This assumption is the base of the Vector Space Model often used in text classification and clustering contexts The function normalize provides a quick and easy way to perform this operation on a single arraylike dataset either using the l1orl2norms

X   1 1 2

Sparse input

normalize andNormalizer accept both dense arraylike and sparse matrices from scipysparse as input For sparse input the data is converted to the Compressed Sparse Rows representation seescipysparse csrmatrix before being fed to efficient Cython routines To avoid unnecessary memory copies it is recommended to choose the CSR representation upstream

Encoding categorical features
Often features are not given as continuous values but categorical For example a person could have fea
turesmale female from Europe from US from Asia uses Firefox
uses Chrome uses Safari uses Internet Explorer Such features can be efficiently
coded as integers for instance male from US uses Internet Explorer could be expressed
as0 1 3 whilefemale from Asia uses Chrome would be1 2 1
To convert categorical features to such integer codes we can use the OrdinalEncoder This estimator transforms
each categorical feature to one new feature of integers 0 to ncategories 1
enc preprocessingOrdinalEncoder
X male from US uses Safari female from Europe uses Firefox
‘→
encfitX
OrdinalEncodercategoriesauto dtype numpyfloat64
enctransformfemale from US uses Safari
array0 1 1
Such integer representation can however not be used directly with all scikitlearn estimators as these expect continu
ous input and would interpret the categories as being ordered which is often not desired ie the set of browsers was
ordered arbitrarily
Another possibility to convert categorical features to features that can be used with scikitlearn estimators is
to use a oneofK also known as onehot or dummy encoding This type of encoding can be obtained with
theOneHotEncoder which transforms each categorical feature with ncategories possible values into
ncategories binary features with one of them 1 and all others 0
Continuing the example above
enc preprocessingOneHotEncoder
X male from US uses Safari female from Europe uses Firefox
‘→
encfitX
OneHotEncodercategoricalfeaturesNone categoriesNone dropNone
dtype numpyfloat64 handleunknownerror
nvaluesNone sparseTrue
enctransformfemale from US uses Safari
 male from Europe uses Safaritoarray
array1 0 0 1 0 1
0 1 1 0 0 1
By default the values each feature can take is inferred automatically from the dataset and can be found in the
categories attribute
enccategories
arrayfemale male dtypeobject arrayfrom Europe from US
‘→dtypeobject arrayuses Firefox uses Safari dtypeobject
It is possible to specify this explicitly using the parameter categories There are two genders four possible
continents and four web browsers in our dataset
genders female male
locations from Africa from Asia from Europe from US
browsers uses Chrome uses Firefox uses IE uses Safari
enc preprocessingOneHotEncodercategoriesgenders locations browsers
 Note that for there are missing categorical values for the 2nd and 3rd
 feature

```
X  male from US uses Safari female from Europe uses Firefox
‘→
encfitX
OneHotEncodercategoricalfeaturesNone
categories dropNone
dtype numpyfloat64 handleunknownerror
nvaluesNone sparseTrue
enctransformfemale from Asia uses Chrometoarray
array1 0 0 1 0 0 1 0 0 0
```
If there is a possibility that the training data might have missing categorical features it can often be better to specify handleunknownignore instead of setting the categories manually as above Whenhandleunknownignore is specified and unknown categories are encountered during trans form no error will be raised but the resulting onehot encoded columns for this feature will be all zeros handleunknownignore is only supported for onehot encoding
```
enc  preprocessingOneHotEncoderhandleunknownignore
X  male from US uses Safari female from Europe uses Firefox
‘→
encfitX
OneHotEncodercategoricalfeaturesNone categoriesNone dropNone
dtype numpyfloat64 handleunknownignore
nvaluesNone sparseTrue
enctransformfemale from Asia uses Chrometoarray
array1 0 0 0 0 0
```
It is also possible to encode each column into ncategories 1 columns instead of ncategories columns by using the drop parameter This parameter allows the user to specify a category for each feature to be dropped This is useful to avoid colinearity in the input matrix in some classifiers Such functionality is useful for example when using nonregularized regression LinearRegression since colinearity would cause the covariance matrix to be noninvertible When this paramenter is not None handleunknown must be set to error
```
X  male from US uses Safari female from Europe uses Firefox
‘→
dropenc  preprocessingOneHotEncoderdropfirstfitX
dropenccategories
arrayfemale male dtypeobject arrayfrom Europe from US
‘→dtypeobject arrayuses Firefox uses Safari dtypeobject
dropenctransformXtoarray
array1 1 1
0 0 0
```
SeeLoading features from dicts for categorical features that are represented as a dict not as scalars

Discretization

Discretization otherwise known as quantization or binning provides a way to partition continuous features into dis crete values Certain datasets with continuous features may benefit from discretization because discretization can transform the dataset of continuous attributes to one with only nominal attributes

Onehot encoded discretized features can make a model more expressive while maintaining interpretability For instance preprocessing with a discretizer can introduce nonlinearity to linear models

Kbins discretization
KBinsDiscretizer discretizes features into kbins
X nparray 3 5 15
  0 6 14
  6 3 11
est preprocessingKBinsDiscretizernbins3 2 2 encodeordinalfitX
By default the output is onehot encoded into a sparse matrix See Encoding categorical features and this can be configured with the encode parameter For each feature the bin edges are computed during fit and together with the number of bins they will define the intervals Therefore for the current example these intervals are defined as
• feature 1 −∞−1−122∞
• feature 2 −∞55∞
• feature 3 −∞1414∞
Based on these bin intervals Xis transformed as follows
esttransformX
array 0 1 1
 1 1 1
 2 0 0
The resulting dataset contains ordinal attributes which can be further used in a sklearnpipelinePipeline
Discretization is similar to constructing histograms for continuous data However histograms focus on counting features which fall into particular bins whereas discretization focuses on assigning feature values to these bins
KBinsDiscretizer implements different binning strategies which can be selected with the strategy parame
ter The ‘uniform’ strategy uses constantwidth bins The ‘quantile’ strategy uses the quantiles values to have equally populated bins in each feature The ‘kmeans’ strategy defines bins based on a kmeans clustering procedure performed on each feature independently
Examples
•Using KBinsDiscretizer to discretize continuous features
•Feature discretization
•Demonstrating the different strategies of KBinsDiscretizer
Feature binarization
Feature binarization is the process of thresholding numerical features to get boolean values This can be useful for downstream probabilistic estimators that make assumption that the input data is distributed according to a multivariate Bernoulli distribution For instance this is the case for the sklearnneuralnetworkBernoulliRBM
It is also common among the text processing community to use binary feature values probably to simplify the probabilistic reasoning even if normalized counts aka term frequencies or TFIDF valued features often perform slightly better in practice
As for the Normalizer the utility class Binarizer is meant to be used in the early stages of sklearn pipelinePipeline Thefit method does nothing as each sample is treated independently of others

Custom transformers
Often you will want to convert an existing Python function into a transformer to assist in data cleaning or processing
You can implement a transformer from an arbitrary function with FunctionTransformer For example to build
a transformer that applies a log transformation in a pipeline do
import numpy as np
from sklearnpreprocessing import FunctionTransformer
transformer FunctionTransformernplog1p validate True
X nparray0 1 2 3
transformertransformX
array0 069314718
109861229 138629436
You can ensure that func andinversefunc are the inverse of each other by setting checkinverseTrue
and calling fit beforetransform Please note that a warning is raised and can be turned into an error with a
filterwarnings
import warnings
warningsfilterwarningserror message checkinverse
categoryUserWarning append False
For a full code example that demonstrates using a FunctionTransformer to do custom feature selection see
Using FunctionTransformer to select columns
354 Imputation of missing values
For various reasons many real world datasets contain missing values often encoded as blanks NaNs or other place
holders Such datasets however are incompatible with scikitlearn estimators which assume that all values in an array

are numerical and that all have and hold meaning A basic strategy to use incomplete datasets is to discard entire rows andor columns containing missing values However this comes at the price of losing data which may be valuable even though incomplete A better strategy is to impute the missing values ie to infer them from the known part of the data See the Glossary of Common Terms and API Elements entry on imputation

Univariate vs Multivariate Imputation

One type of imputation algorithm is univariate which imputes values in the ith feature dimension using only non missing values in that feature dimension eg imputeSimpleImputer By contrast multivariate imputation algorithms use the entire set of available feature dimensions to estimate the missing values eg impute IterativeImputer

Univariate feature imputation

TheSimpleImputer class provides basic strategies for imputing missing values Missing values can be imputed with a provided constant value or using the statistics mean median or most frequent of each column in which the missing values are located This class also allows for different missing values encodings

The following snippet demonstrates how to replace missing values encoded as npnan using the mean value of the columns axis 0 that contain the missing values

```
 import numpy as np
 from sklearnimpute import SimpleImputer
imp  SimpleImputermissingvaluesnpnan strategymean
impfit1 2 npnan 3 7 6
SimpleImputeraddindicatorFalse copyTrue fillvalueNone
missingvaluesnan strategymean verbose0
X  npnan 2 6 npnan 7 6
printimptransformX
4 2
6 3666
7 6
```

TheSimpleImputer class also supports sparse matrices

```
 import scipysparse as sp
X  spcscmatrix1 2 0 1 8 4
imp  SimpleImputermissingvalues1 strategymean
impfitX
SimpleImputeraddindicatorFalse copyTrue fillvalueNone
missingvalues1 strategymean verbose0
Xtest  spcscmatrix1 2 6 1 7 6
printimptransformXtesttoarray
3 2
6 3
7 6
```

Note that this format is not meant to be used to implicitly store missing values in the matrix because it would densify it at transform time Missing values encoded by 0 must be used with dense input

TheSimpleImputer class also supports categorical data represented as string values or pandas categoricals when using themostfrequent orconstant strategy

```
 import pandas as pd
df  pdDataFramea x
 npnan y
```

```
 a npnan
 b y dtypecategory

imp  SimpleImputerstrategymostfrequent
printimpfittransformdf
a x
a y
a y
b y
```
Multivariate feature imputation

A more sophisticated approach is to use the IterativeImputer class which models each feature with missing values as a function of other features and uses that estimate for imputation It does so in an iterated roundrobin fashion at each step a feature column is designated as output yand the other feature columns are treated as inputs X A regressor is fit on X y for knowny Then the regressor is used to predict the missing values of y This is done for each feature in an iterative fashion and then is repeated for maxiter imputation rounds The results of the final imputation round are returned

Note This estimator is still experimental for now the predictions and the API might change without any deprecation cycle To use it you need to explicitly import enableiterativeimputer

```
 import numpy as np
 from sklearnexperimental import enableiterativeimputer
 from sklearnimpute import IterativeImputer
imp  IterativeImputermaxiter10 randomstate0
impfit1 2 3 6 4 8 npnan 3 7 npnan
IterativeImputeraddindicatorFalse estimatorNone
imputationorderascending initialstrategymean
maxiter10 maxvalueNone minvalueNone
missingvaluesnan nnearestfeaturesNone
randomstate0 sampleposteriorFalse tol0001
verbose0
Xtest  npnan 2 6 npnan npnan 6
 the model learns that the second feature is double the first
printnproundimptransformXtest
 1 2
 6 12
 3 6
```

BothSimpleImputer andIterativeImputer can be used in a Pipeline as a way to build a composite estimator that supports imputation See Imputing missing values before building an estimator

Flexibility of IterativeImputer

There are many wellestablished imputation packages in the R data science ecosystem Amelia mi mice miss Forest etc missForest is popular and turns out to be a particular instance of different sequential imputation algorithms that can all be implemented with IterativeImputer by passing in different regressors to be used for predicting missing feature values In the case of missForest this regressor is a Random Forest See sphxglrautoexamplesplotiterativeimputervariantscomparisonpy

Multiple vs Single Imputation
In the statistics community it is common practice to perform multiple imputations generating for example mseparate imputations for a single feature matrix Each of these mimputations is then put through the subsequent analysis pipeline eg feature engineering clustering regression classification The mfinal analysis results eg heldout validation errors allow the data scientist to obtain understanding of how analytic results may differ as a consequence of the inherent uncertainty caused by the missing values The above practice is called multiple imputation
Our implementation of IterativeImputer was inspired by the R MICE package Multivariate Imputation by Chained Equations1 but differs from it by returning a single imputation instead of multiple imputations However IterativeImputer can also be used for multiple imputations by applying it repeatedly to the same dataset with different random seeds when sampleposteriorTrue See2 chapter 4 for more discussion on multiple vs single imputations
It is still an open problem as to how useful single vs multiple imputation is in the context of prediction and classifica tion when the user is not interested in measuring uncertainty due to missing values
Note that a call to the transform method ofIterativeImputer is not allowed to change the number of samples Therefore multiple imputations cannot be achieved by a single call to transform
References
Marking imputed values
TheMissingIndicator transformer is useful to transform a dataset into corresponding binary matrix indicating the presence of missing values in the dataset This transformation is useful in conjunction with imputation When using imputation preserving the information about which values had been missing can be informative
NaN is usually used as the placeholder for missing values However it enforces the data type to be float The parameter missingvalues allows to specify other placeholder such as integer In the following example we will use 1as missing values
```
 from sklearnimpute import MissingIndicator
X  nparray1 1 1 3
 4 1 0 1
 8 1 1 0
indicator  MissingIndicatormissingvalues1
maskmissingvaluesonly  indicatorfittransformX
maskmissingvaluesonly
array True True False
False True True
False True False
```
Thefeatures parameter is used to choose the features for which the mask is constructed By default it is missingonly which returns the imputer mask of the features containing missing values at fit time
```
indicatorfeatures
array0 1 3
```
Thefeatures parameter can be set to all to returned all features whether or not they contain missing values
```
indicator  MissingIndicatormissingvalues1 featuresall
maskall  indicatorfittransformX
```

355 Unsupervised dimensionality reduction
If your number of features is high it may be useful to reduce it with an unsupervised step prior to supervised steps
Many of the Unsupervised learning methods implement a transform method that can be used to reduce the dimen
sionality Below we discuss two specific example of this pattern that are heavily used
Pipelining
The unsupervised data reduction and the supervised estimator can be chained in one step See Pipeline chaining
estimators

PCA principal component analysis
decompositionPCA looks for a combination of features that capture well the variance of the original features
SeeDecomposing signals in components matrix factorization problems
Examples
•Faces recognition example using eigenfaces and SVMs
Random projections
The module randomprojection provides several tools for data reduction by random projections See the
relevant section of the documentation Random Projection
Examples
•The JohnsonLindenstrauss bound for embedding with random projections
Feature agglomeration
clusterFeatureAgglomeration applies Hierarchical clustering to group together features that behave sim
ilarly
Examples
•Feature agglomeration vs univariate selection
•Feature agglomeration
Feature scaling
Note that if features have very different scaling or statistical properties clusterFeatureAgglomeration
may not be able to capture the links between related features Using a preprocessingStandardScaler
can be useful in these settings
356 Random Projection
Thesklearnrandomprojection module implements a simple and computationally efficient way to reduce
the dimensionality of the data by trading a controlled amount of accuracy as additional variance for faster processing
times and smaller model sizes This module implements two types of unstructured random matrix Gaussian random
matrix andsparse random matrix
The dimensions and distribution of random projections matrices are controlled so as to preserve the pairwise distances
between any two samples of the dataset Thus random projection is a suitable approximation technique for distance
based method

The JohnsonLindenstrauss lemma
The main theoretical result behind the efficiency of random projection is the JohnsonLindenstrauss lemma quoting Wikipedia
In mathematics the JohnsonLindenstrauss lemma is a result concerning lowdistortion embeddings of points from highdimensional into lowdimensional Euclidean space The lemma states that a small set of points in a highdimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved The map used for the embedding is at least Lipschitz and can even be taken to be an orthogonal projection
Knowing only the number of samples the sklearnrandomprojection johnsonlindenstraussmindim estimates conservatively the minimal size of the random subspace to guarantee a bounded distortion introduced by the random projection
```
from sklearnrandomprojection import johnsonlindenstraussmindim
johnsonlindenstraussmindimnsamples1e6 eps05
663
johnsonlindenstraussmindimnsamples1e6 eps05 01 001
array 663 11841 1112658
johnsonlindenstraussmindimnsamples1e4 1e5 1e6 eps01
array 7894 9868 11841
```
Example
• See The JohnsonLindenstrauss bound for embedding with random projections for a theoretical explication on the JohnsonLindenstrauss lemma and an empirical validation using sparse random matrices

Gaussian random projection
ThesklearnrandomprojectionGaussianRandomProjection reduces the dimensionality by pro jecting the original input space on a randomly generated matrix where components are drawn from the following distribution □01
□□□□□□□□□□□□
Here a small excerpt which illustrates how to use the Gaussian random projection transformer

```
 import numpy as np
 from sklearn import randomprojection
X  nprandomrand100 10000
transformer  randomprojectionGaussianRandomProjection
Xnew  transformerfittransformX
Xnewshape
100 3947
```
Sparse random projection

TheskIearnrandomprojectionSparseRandomProjection reduces the dimensionality by projecting the original input space using a sparse random matrix

Sparse random matrices are an alternative to dense Gaussian random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data

If we define s 1 density the elements of the random matrix are drawn from

−√

components12

0 with probability 1−1

√

components12

where components is the size of the projected subspace By default the density of non zero elements is set to the minimum density as recommended by Ping Li et al 1√features

Here a small excerpt which illustrates how to use the sparse random projection transformer

```
 import numpy as np
 from sklearn import randomprojection
X  nprandomrand100 10000
transformer  randomprojectionSparseRandomProjection
Xnew  transformerfittransformX
Xnewshape
100 3947
```

357 Kernel Approximation

This submodule contains functions that approximate the feature mappings that correspond to certain kernels as they are used for example in support vector machines see Support Vector Machines The following feature functions perform nonlinear transformations of the input which can serve as a basis for linear classification or other algorithms

The advantage of using approximate explicit feature maps compared to the kernel trick which makes use of feature maps implicitly is that explicit mappings can be better suited for online learning and can significantly reduce the cost of learning with very large datasets Standard kernelized SVMs do not scale well to large datasets but using an

approximate kernel map it is possible to use much more efficient linear SVMs In particular the combination of kernel map approximations with SGDClassifier can make nonlinear learning on large datasets possible
Since there has not been much empirical work using approximate embeddings it is advisable to compare results against exact kernel methods when possible
See also
Polynomial regression extending linear models with basis functions for an exact polynomial transformation
Nystroem Method for Kernel Approximation
The Nystroem method as implemented in Nystroem is a general method for lowrank approximations of kernels It achieves this by essentially subsampling the data on which the kernel is evaluated By default Nystroem uses the rbf kernel but it can use any kernel function or a precomputed kernel matrix The number of samples used which is also the dimensionality of the features computed is given by the parameter ncomponents
Radial Basis Function Kernel
TheRBFSampler constructs an approximate mapping for the radial basis function kernel also known as Random Kitchen Sinks RR2007 This transformation can be used to explicitly model a kernel map prior to applying a linear algorithm for example a linear SVM
```
 from sklearnkernelapproximation import RBFSampler
 from sklearnlinearmodel import SGDClassifier
X  0 0 1 1 1 0 0 1
y  0 0 1 1
rbffeature  RBFSamplergamma1 randomstate1
Xfeatures  rbffeaturefittransformX
clf  SGDClassifiermaxiter5
clffitXfeatures y
SGDClassifieralpha00001 averageFalse classweightNone
earlystoppingFalse epsilon01 eta000 fitinterceptTrue
l1ratio015 learningrateoptimal losshinge maxiter5
niternochange5 njobsNone penaltyl2 powert05
randomstateNone shuffleTrue tol0001 validationfraction01
verbose0 warmstartFalse
clfscoreXfeatures y
10
```
The mapping relies on a Monte Carlo approximation to the kernel values The fit function performs the Monte Carlo sampling whereas the transform method performs the mapping of the data Because of the inherent randomness of the process results may vary between different calls to the fit function
Thefit function takes two arguments ncomponents which is the target dimensionality of the feature transform andgamma the parameter of the RBFkernel A higher ncomponents will result in a better approximation of the kernel and will yield results more similar to those produced by a kernel SVM Note that “fitting” the feature function does not actually depend on the data given to the fit function Only the dimensionality of the data is used Details on the method can be found in RR2007
For a given value of ncomponents RBFSampler is often less accurate as Nystroem RBFSampler is cheaper to compute though making use of larger feature spaces more efficient
Examples

Fig 39 Comparing an exact RBF kernel left with the approximation right
•Explicit feature map approximation for RBF kernels
Additive Chi Squared Kernel
The additive chi squared kernel is a kernel on histograms often used in computer vision
The additive chi squared kernel as used here is given by
□□ □ ∑
□2□□□□
□□□□
This is not exactly the same as sklearnmetricsadditivechi2kernel The authors of VZ2010 prefer
the version above as it is always positive definite Since the kernel is additive it is possible to treat all components
□□separately for embedding This makes it possible to sample the Fourier transform in regular intervals instead of
approximating using Monte Carlo sampling
The classAdditiveChi2Sampler implements this component wise deterministic sampling Each component
is sampled □times yielding 2□ 1 dimensions per input dimension the multiple of two stems from the real and
complex part of the Fourier transform In the literature □is usually chosen to be 1 or 2 transforming the dataset to
sizensamples 5nfeatures in the case of □ 2
The approximate feature map provided by AdditiveChi2Sampler can be combined with the approximate feature
map provided by RBFSampler to yield an approximate feature map for the exponentiated chi squared kernel See
theVZ2010 for details and VVZ2010 for combination with the RBFSampler
Skewed Chi Squared Kernel
The skewed chi squared kernel is given by
□□ □ ∏
□2√□□□√□□□
□□□□ 2□
It has properties that are similar to the exponentiated chi squared kernel often used in computer vision but allows for
a simple Monte Carlo approximation of the feature map

The usage of the SkewedChi2Sampler is the same as the usage described above for the RBFSampler The only difference is in the free parameter that is called For a motivation for this mapping and the mathematical details see LS2010

Mathematical Details

Kernel methods like support vector machines or kernelized PCA rely on a property of reproducing kernel Hilbert spaces For any positive definite kernel function a so called Mercer kernel it is guaranteed that there exists a mapping into a Hilbert space $\mathcal{H}$ such that

⟨ ⟩

Where⟨··⟩denotes the inner product in the Hilbert space

If an algorithm such as a linear support vector machine or PCA relies only on the scalar product of data points one may use the value of which corresponds to applying the algorithm to the mapped data points The advantage of using is that the mapping never has to be calculated explicitly allowing for arbitrary large features even infinite

One drawback of kernel methods is that it might be necessary to store many kernel values during optimiza tion If a kernelized classifier is applied to new data needs to be computed to make predictions possibly for many different in the training set

The classes in this submodule allow to approximate the embedding thereby working explicitly with the representa tions which obviates the need to apply the kernel or store training examples

358 Pairwise metrics Affinities and Kernels

Thesklearnmetricspairwise submodule implements utilities to evaluate pairwise distances or affinity of sets of samples

This module contains both distance metrics and kernels A brief summary is given on the two here

Distance metrics are functions da b such thatda b da c if objectsaandbare considered “more similar” than objects aandc Two objects exactly alike would have a distance of zero One of the most popular examples is Euclidean distance To be a ‘true’ metric it must obey the following four conditions

1 da b 0 forall aandb

2 da b 0 if andonlyifa b positive definiteness

3 da b db a symmetry

4 da c da b db c the triangle inequality

Kernels are measures of similarity ie sa b sa c if objectsaandbare considered “more similar” than objectsaandc A kernel must also be positive semidefinite

There are a number of ways to convert between a distance metric and a similarity measure such as a kernel Let Dbe the distance and Sbe the kernel

1S npexpD gamma where one heuristic for choosing gamma is1 numfeatures

2S 1 D npmaxD

The distances between the row vectors of Xand the row vectors of Ycan be evaluated using pairwisedistances
IfYis omitted the pairwise distances of the row vectors of Xare calculated Similarly pairwise
pairwisekernels can be used to calculate the kernel between XandYusing different kernel functions See
the API reference for more details
```
 import numpy as np
 from sklearnmetrics import pairwisedistances
 from sklearnmetricspairwise import pairwisekernels
X  nparray2 3 3 5 5 8

3 0 5
8 5 0
pairwisekernelsX Y metriclinear
array 2 7
 3 11
 5 18
```
Cosine similarity
cosinesimilarity computes the L2normalized dot product of vectors That is if □and□are row vectors their
cosine similarity □is defined as
□□ □ □□⊤
‖□‖‖□‖
This is called cosine similarity because Euclidean L2 normalization projects the vectors onto the unit sphere and
their dot product is then the cosine of the angle between the points denoted by the vectors
This kernel is a popular choice for computing the similarity of documents represented as tfidf vectors
cosinesimilarity acceptsscipysparse matrices Note that the tfidf functionality in sklearn
featureextractiontext can produce normalized vectors in which case cosinesimilarity is equiv

Linear kernel
The function linearkernel computes the linear kernel that is a special case of polynomialkernel with
degree1 andcoef00 homogeneous If xandyare column vectors their linear kernel is
□□ □ □⊤□

Polynomial kernel

The function polynomialkernel computes the degreed polynomial kernel between two vectors The polyno
mial kernel represents the similarity between two vectors Conceptually the polynomial kernels considers not only
the similarity between vectors under the same dimension but also across dimensions When used in machine learning
algorithms this allows to account for feature interaction

The polynomial kernel is defined as

□□ □ □□⊤□□0□

where

•xyare the input vectors

•dis the kernel degree

If□0 0the kernel is said to be homogeneous

Sigmoid kernel

The function sigmoidkernel computes the sigmoid kernel between two vectors The sigmoid kernel is also
known as hyperbolic tangent or Multilayer Perceptron because in the neural network field it is often used as neuron
activation function It is defined as

□□ □ tanh □□⊤□□0

where

•xyare the input vectors

•□is known as slope

•□0is known as intercept

RBF kernel

The function rbfkernel computes the radial basis function RBF kernel between two vectors This kernel is
defined as

□□ □ exp−□‖□−□‖2

wherexandyare the input vectors If □□−2the kernel is known as the Gaussian kernel of variance □2

Laplacian kernel

The function laplaciankernel is a variant on the radial basis function kernel defined as

□□ □ exp−□‖□−□‖1

wherexandyare the input vectors and ‖□−□‖1is the Manhattan distance between the input vectors

It has proven useful in ML applied to noiseless data See eg Machine learning for quantum mechanics in a nutshell

Chisquared kernel
The chisquared kernel is a very popular choice for training nonlinear SVMs in computer vision applications It can be computed using chi2kernel and then passed to an sklearnsvmSVC withkernelprecomputed

```
 from sklearnsvm import SVC
 from sklearnmetricspairwise import chi2kernel
X  0 1 1 0 2 8 7 3
y  0 1 0 1
K  chi2kernelX gamma5

089483932 051341712 1  07768366
058364548 083822343 07768366  1
svm  SVCkernelprecomputedfitK y
svmpredictK
array0 1 0 1
```

It can also be directly used as the kernel argument

```
svm  SVCkernelchi2kernelfitX y
svmpredictX
array0 1 0 1
```

The chi squared kernel is given by
□□ □ exp
−□∑
□□□−□□2
□□ □□
The data is assumed to be nonnegative and is often normalized to have an L1norm of one The normalization is rationalized with the connection to the chi squared distance which is a distance between discrete probability distributions
The chi squared kernel is most commonly used on histograms bags of visual words

36 Dataset loading utilities
Thesklearndatasets package embeds some small toy datasets as introduced in the Getting Started section
This package also features helpers to fetch larger datasets commonly used by the machine learning community to benchmark algorithms on data that comes from the ‘real world’

To evaluate the impact of the scale of the dataset nsamples andnfeatures while controlling the statistical properties of the data typically the correlation and informativeness of the features it is also possible to generate synthetic data

361 General dataset API

There are three main kinds of dataset interfaces that can be used to get datasets depending on the desired type of dataset

The dataset loaders They can be used to load small standard datasets described in the Toy datasets section

The dataset fetchers They can be used to download and load larger datasets described in the Real world datasets section

Both loaders and fetchers functions return a dictionarylike object holding at least two items an array of shape nsamples nfeatures with keydata except for 20newsgroups and a numpy array of length nsamples containing the target values with key target

It’s also possible for almost all of these function to constrain the output to be a tuple containing only the data and the target by setting the returnXy parameter to True

The datasets also contain a full description in their DESCR attribute and some contain featurenames and targetnames See the dataset descriptions below for details

The dataset generation functions They can be used to generate controlled synthetic datasets described in the Generated datasets section

These functions return a tuple X y consisting of a nsamples nfeatures numpy array Xand an array of lengthnsamples containing the targets y

In addition there are also miscellaneous tools to load datasets of other formats or from other locations described in theLoading other datasets section

362 Toy datasets

scikitlearn comes with a few small standard datasets that do not require to download any file from some external website

They can be loaded using the following functions

loadboston returnXy Load and return the boston houseprices dataset regres
sion

loadiris returnXy Load and return the iris dataset classification

loaddiabetes returnXy Load and return the diabetes dataset regression

loaddigits nclass returnXy Load and return the digits dataset classification

loadlinnerud returnXy Load and return the linnerud dataset multivariate regres
sion

loadwine returnXy Load and return the wine dataset classification

loadbreastcancer returnXy Load and return the breast cancer wisconsin dataset clas
sification

These datasets are useful to quickly illustrate the behavior of the various algorithms implemented in scikitlearn They are however often too small to be representative of real world machine learning tasks

Date July 1988
The famous Iris database first used by Sir RA Fisher The dataset is taken from Fisher’s paper Note that it’s the same as in R but not as in the UCI Machine Learning Repository which has two wrong data points
This is perhaps the best known database to be found in the pattern recognition literature Fisher’s paper is a classic in the field and is referenced frequently to this day See Duda Hart for example The data set contains 3 classes of 50 instances each where each class refers to a type of iris plant One class is linearly separable from the other 2 the latter are NOT linearly separable from each other

Date July 1998
This is a copy of the test set of the UCI ML handwritten digits datasets httpsarchiveicsuciedumldatasetsOptical RecognitionofHandwrittenDigits
The data set contains images of handwritten digits 10 classes where each class refers to a digit
Preprocessing programs made available by NIST were used to extract normalized bitmaps of handwritten digits from a preprinted form From a total of 43 people 30 contributed to the training set and different 13 to the test set 32x32 bitmaps are divided into nonoverlapping blocks of 4x4 and the number of on pixels are counted in each block This generates an input matrix of 8x8 where each element is an integer in the range 016 This reduces dimensionality and gives invariance to small distortions

363 Real world datasets
scikitlearn provides tools to load larger datasets downloading them if necessary
They can be loaded using the following functions
fetcholivettifaces datahome shuffle Load the Olivetti faces dataset from ATT classification
fetch20newsgroups datahome subset Load the filenames and data from the 20 newsgroups dataset classification
fetch20newsgroupsvectorized subset Load the 20 newsgroups dataset and vectorize it into token counts classification
fetchlfwpeople datahome funneled Load the Labeled Faces in the Wild LFW people dataset classification
fetchlfwpairs subset datahome Load the Labeled Faces in the Wild LFW pairs dataset classification
fetchcovtype datahome Load the covertype dataset classification
fetchrcv1 datahome subset Load the RCV1 multilabel dataset classification
fetchkddcup99 subset datahome shuffle Load the kddcup99 dataset classification
fetchcaliforniahousing datahome Load the California housing dataset regression
The Olivetti faces dataset
This dataset contains a set of face images taken between April 1992 and April 1994 at ATT Laboratories Cam bridge The sklearndatasetsfetcholivettifaces function is the data fetching caching function that downloads the data archive from ATT
As described on the original website
There are ten different images of each of 40 distinct subjects For some subjects the images were taken

at different times varying the lighting facial expressions open closed eyes smiling not smiling and
facial details glasses no glasses All the images were taken against a dark homogeneous background
with the subjects in an upright frontal position with tolerance for some side movement
Data Set Characteristics
Classes 40
Samples total 400
Dimensionality 4096
Features real between 0 and 1
The image is quantized to 256 grey levels and stored as unsigned 8bit integers the loader will convert these to floating
point values on the interval 0 1 which are easier to work with for many algorithms
The “target” for this database is an integer from 0 to 39 indicating the identity of the person pictured however with
only 10 examples per class this relatively small dataset is more interesting from an unsupervised or semisupervised
perspective
The original dataset consisted of 92 x 112 while the version available here consists of 64x64 images
When using these images please give credit to ATT Laboratories Cambridge
The 20 newsgroups text dataset
The 20 newsgroups dataset comprises around 18000 newsgroups posts on 20 topics split in two subsets one for
training or development and the other one for testing or for performance evaluation The split between the train
and test set is based upon a messages posted before and after a specific date
This module contains two loaders The first one sklearndatasetsfetch20newsgroups returns a list
of the raw texts that can be fed to text feature extractors such as sklearnfeatureextractiontext
CountVectorizer with custom parameters so as to extract feature vectors The second one sklearn
datasetsfetch20newsgroupsvectorized returns readytouse features ie it is not necessary to use
a feature extractor
Data Set Characteristics

Converting text to vectors
In order to feed predictive or clustering models with the text data one first need to turn the text into vectors
of numerical values suitable for statistical analysis This can be achieved with the utilities of the sklearn
featureextractiontext as demonstrated in the following example that extract TFIDF vectors of unigram
tokens from a subset of 20news
 from sklearnfeatureextractiontext import TfidfVectorizer

15901327
sklearndatasetsfetch20newsgroupsvectorized is a function which returns readytouse token counts features instead of file names
Filtering text for more realistic training
It is easy for a classifier to overfit on particular things that appear in the 20 Newsgroups data such as newsgroup headers Many classifiers achieve very high Fscores but their results would not generalize to other documents that aren’t from this window of time
For example let’s look at the results of a multinomial Naive Bayes classifier which is fast to train and achieves a decent Fscore
```
 from sklearnnaivebayes import MultinomialNB
 from sklearn import metrics
newsgroupstest  fetch20newsgroupssubsettest
 categoriescategories
vectorstest  vectorizertransformnewsgroupstestdata
clf  MultinomialNBalpha01
clffitvectors newsgroupstraintarget
MultinomialNBalpha001 classpriorNone fitpriorTrue
pred  clfpredictvectorstest
metricsf1scorenewsgroupstesttarget pred averagemacro
088213
```
The example Classification of text documents using sparse features shuffles the training and test data instead of segmenting by time and in that case multinomial Naive Bayes gets a much higher Fscore of 088 Are you suspicious yet of what’s going on inside this classifier
Let’s take a look at what the most informative features are
```
 import numpy as np
 def showtop10classifier vectorizer categories
 featurenames  npasarrayvectorizergetfeaturenames
 for i category inenumeratecategories
 top10  npargsortclassifiercoefi10
 printss  category  joinfeaturenamestop10

showtop10clf vectorizer newsgroupstraintargetnames
altatheism edu it and in you that is of to the
compgraphics edu in graphics it is for and of to the
scispace edu it that is in and space to of the
talkreligionmisc not it you in is that and to of the
```
You can now see many things that these features have overfit to

• Almost every group is distinguished by whether headers such as NNTPPostingHost and
Distribution appear more or less often
• Another significant feature involves whether the sender is affiliated with a university as indicated either by their
headers or their signature
• The word “article” is a significant feature based on how often people quote previous posts like this “In article
article ID name email address wrote”
• Other features match the names and email addresses of particular people who were posting at the time
With such an abundance of clues that distinguish newsgroups the classifiers barely have to identify topics from text at
all and they all perform at the same high level
For this reason the functions that load 20 Newsgroups data provide a parameter called remove telling it what
kinds of information to strip out of each file remove should be a tuple containing any subset of headers
footers quotes telling it to remove headers signature blocks and quotation blocks respectively
```
newsgroupstest  fetch20newsgroupssubsettest
 removeheaders footers quotes
 categoriescategories
vectorstest  vectorizertransformnewsgroupstestdata
pred  clfpredictvectorstest
metricsf1scorepred newsgroupstesttarget averagemacro
```
077310
This classifier lost over a lot of its Fscore just because we removed metadata that has little to do with topic classifi
cation It loses even more if we also strip this metadata from the training data
```
newsgroupstrain  fetch20newsgroupssubsettrain
 removeheaders footers quotes
 categoriescategories
vectors  vectorizerfittransformnewsgroupstraindata
clf  MultinomialNBalpha01
clffitvectors newsgroupstraintarget
MultinomialNBalpha001 classpriorNone fitpriorTrue
vectorstest  vectorizertransformnewsgroupstestdata
pred  clfpredictvectorstest
metricsf1scorenewsgroupstesttarget pred averagemacro
```
076995
Some other classifiers cope better with this harder version of the task Try running Sample pipeline for text feature
extraction and evaluation with and without the filter option to compare the results
Recommendation
When evaluating text classifiers on the 20 Newsgroups data you should strip newsgrouprelated metadata In
scikitlearn you can do this by setting removeheaders footers quotes The Fscore will
be lower because it is more realistic
Examples
•Sample pipeline for text feature extraction and evaluation
•Classification of text documents using sparse features

scikitlearn user guide Release 0213
The Labeled Faces in the Wild face recognition dataset
This dataset is a collection of JPEG pictures of famous people collected over the internet all details are available on the official website
httpviswwwcsumassedulfw
Each picture is centered on a single face The typical task is called Face Verification given a pair of two pictures a binary classifier must predict whether the two images are from the same person
An alternative task Face Recognition or Face Identification is given the picture of the face of an unknown person identify the name of the person by referring to a gallery of previously seen pictures of identified persons
Both Face Verification and Face Recognition are tasks that are typically performed on the output of a model trained to perform Face Detection The most popular model for Face Detection is called ViolaJones and is implemented in the OpenCV library The LFW faces were extracted by this face detector from various online websites
Data Set Characteristics
Classes 5749
Samples total 13233
Dimensionality 5828
Features real between 0 and 255
Usage
scikitlearn provides two loaders that will automatically download cache parse the metadata files decode the jpeg and convert the interesting slices into memmapped numpy arrays This dataset size is more than 200 MB The first load typically takes more than a couple of minutes to fully decode the relevant part of the JPEG files into numpy arrays If the dataset has been loaded once the following times the loading times less than 200ms by using a memmapped version memoized on the disk in the scikitlearndatalfwhome folder using joblib
The first loader is used for the Face Identification task a multiclass classification task hence supervised learning
```
 from sklearndatasets import fetchlfwpeople

Kddcup 99 dataset
The KDD Cup ‘99 dataset was created by processing the tcpdump portions of the 1998 DARPA Intrusion Detection System IDS Evaluation dataset created by MIT Lincoln Lab 1 The artificial data described on the dataset’s homepage was generated using a closed network and handinjected attacks to produce a large number of different types of attack with normal activity in the background As the initial goal was to produce a large training set for supervised learning algorithms there is a large proportion 801 of abnormal data which is unrealistic in real world and inappropriate for unsupervised anomaly detection which aims at detecting ‘abnormal’ data ie
1 qualitatively different from normal data
2 in large minority among the observations
We thus transform the KDD Data set into two different data sets SA and SF
SA is obtained by simply selecting all the normal data and a small proportion of abnormal data to gives an anomaly proportion of 1
SF is obtained as in 2 by simply picking up the data whose attribute loggedin is positive thus focusing on the intrusion attack which gives a proportion of 03 of attack
http and smtp are two subsets of SF corresponding with third feature equal to ‘http’ resp to ‘smtp’

sklearndatasetsfetchkddcup99 will load the kddcup99 dataset it returns a dictionarylike object with
the feature matrix in the data member and the target values in target The dataset will be downloaded from the
web if necessary
California Housing dataset
Data Set Characteristics
Number of Instances 20640
Number of Attributes 8 numeric predictive attributes and the target
Attribute Information
• MedInc median income in block
• HouseAge median house age in block
• AveRooms average number of rooms
• AveBedrms average number of bedrooms
• Population block population
• AveOccup average house occupancy
• Latitude house block latitude
• Longitude house block longitude
Missing Attribute Values None
This dataset was obtained from the StatLib repository httplibstatcmuedudatasets
The target variable is the median house value for California districts
This dataset was derived from the 1990 US census using one row per census block group A block group is the
smallest geographical unit for which the US Census Bureau publishes sample data a block group typically has a
population of 600 to 3000 people
It can be downloadedloaded using the sklearndatasetsfetchcaliforniahousing function

364 Generated datasets
In addition scikitlearn includes various random sample generators that can be used to build artificial datasets of controlled size and complexity
Generators for classification and clustering
These generators produce a matrix of features and corresponding discrete targets
Single label
Bothmakeblobs andmakeclassification create multiclass datasets by allocating each class one or more normallydistributed clusters of points makeblobs provides greater control regarding the centers and standard deviations of each cluster and is used to demonstrate clustering makeclassification specialises in introducing noise by way of correlated redundant and uninformative features multiple Gaussian clusters per class and linear transformations of the feature space
makegaussianquantiles divides a single Gaussian cluster into nearequalsize classes separated by concentric hyperspheres makehastie102 generates a similar binary 10dimensional problem
makecircles andmakemoons generate 2d binary classification datasets that are challenging to certain algorithms eg centroidbased clustering or linear classification including optional Gaussian noise They are useful for visualisation makecircles produces Gaussian data with a spherical decision boundary for binary classification while makemoons produces two interleaving half circles

Multilabel
makemultilabelclassification generates random samples with multiple labels reflecting a bag of words drawn from a mixture of topics The number of topics for each document is drawn from a Poisson distribution and the topics themselves are drawn from a fixed random distribution Similarly the number of words is drawn from Poisson with words drawn from a multinomial where each topic defines a probability distribution over words Simplifications with respect to true bagofwords mixtures include

• Pertopic word distributions are independently drawn where in reality all would be affected by a sparse base distribution and would be correlated
• For a document generated from multiple topics all topics are weighted equally in generating its bag of words
• Documents without labels words at random rather than from a base distribution

Biclustering
makebiclusters shape nclusters noise Generate an array with constant block diagonal structure for biclustering
makecheckerboard shape nclusters Generate an array with block checkerboard structure for bi clustering
Generators for regression
makeregression produces regression targets as an optionallysparse random linear combination of random features with noise Its informative features may be uncorrelated or low rank few features account for most of the variance
Other regression generators generate functions deterministically from randomized features makesparseuncorrelated produces a target as a linear combination of four features with fixed coefficients Others encode explicitly nonlinear relations makefriedman1 is related by polynomial and sine transforms makefriedman2 includes feature multiplication and reciprocation and makefriedman3 is similar with an arctan transformation on the target
Generators for manifold learning
makescurve nsamples noise randomstate Generate an S curve dataset
makeswissroll nsamples noise randomstate Generate a swiss roll dataset

Generators for decomposition
makelowrankmatrix nsamples Generate a mostly low rank matrix with bellshaped singu
lar values
makesparsecodedsignal nsamples Generate a signal as a sparse combination of dictionary el
ements
makespdmatrix ndim randomstate Generate a random symmetric positivedefinite matrix
makesparsespdmatrix dim alpha Generate a sparse symmetric definite positive matrix
365 Loading other datasets
Sample images
Scikitlearn also embed a couple of sample JPEG images published under Creative Commons license by their authors
Those images can be useful to test algorithms and pipeline on 2D data
loadsampleimages Load sample images for image manipulation
loadsampleimage imagename Load the numpy array of a single sample image
Warning The default coding of images is based on the uint8 dtype to spare memory Often machine learning
algorithms work best if the input is converted to a floating point representation first Also if you plan to use
matplotlibpyplptimshow don’t forget to scale to the range 0 1 as done in the following example
Examples
•Color Quantization using KMeans
Datasets in svmlight libsvm format
scikitlearn includes utility functions for loading datasets in the svmlight libsvm format In this format each line
takes the form label featureidfeaturevalue featureidfeaturevalue
This format is especially suitable for sparse datasets In this module scipy sparse CSR matrices are used for Xand
numpy arrays are used for y
You may load a dataset like as follows
from sklearndatasets import loadsvmlightfile
Xtrain ytrain loadsvmlightfilepathtotraindatasettxt

You may also load two or more datasets at once
Xtrain ytrain Xtest ytest loadsvmlightfiles
 pathtotraindatasettxt pathtotestdatasettxt

In this case Xtrain andXtest are guaranteed to have the same number of features Another way to achieve the same result is to fix the number of features
Xtest ytest loadsvmlightfile
 pathtotestdatasettxt nfeaturesXtrainshape1

Dataset Versions
A dataset is uniquely specified by its dataid but not necessarily by its name Several different “versions” of a
dataset with the same name can exist which can contain entirely different datasets If a particular version of a dataset
has been found to contain significant issues it might be deactivated Using a name to specify a dataset will yield the
earliest version of a dataset that is still active That means that fetchopenmlnamemiceprotein can
yield different results at different times if earlier versions become inactive You can see that the dataset with dataid
40966 that we fetched above is the version 1 of the “miceprotein” dataset
micedetailsversion
1
In fact this dataset only has one version The iris dataset on the other hand has multiple versions
iris fetchopenmlnameiris

Loading from external datasets
scikitlearn works on any numeric data stored as numpy arrays or scipy sparse matrices Other types that are convertible to numeric arrays such as pandas DataFrame are also acceptable
Here are some recommended ways to load standard columnar data into a format usable by scikitlearn
• pandasio provides tools to read data from common formats including CSV Excel JSON and SQL DataFrames may also be constructed from lists of tuples or dicts Pandas handles heterogeneous data smoothly and provides tools for manipulation and conversion into a numeric array suitable for scikitlearn
• scipyio specializes in binary formats often used in scientific computing context such as mat and arff
• numpyroutinesio for standard loading of columnar data into numpy arrays
• scikitlearn’s datasetsloadsvmlightfile for the svmlight or libSVM sparse format
• scikitlearn’s datasetsloadfiles for directories of text files where the name of each directory is the name of each category and each file inside of each directory corresponds to one sample from that category
For some miscellaneous data such as images videos and audio you may wish to refer to
• skimageio or Imageio for loading images and videos into numpy arrays
• scipyiowavfileread for reading WA V files into a numpy array
Categorical or nominal features stored as strings common in pandas DataFrames will need converting to numerical features using sklearnpreprocessingOneHotEncoder orsklearnpreprocessing OrdinalEncoder or similar See Preprocessing data

Note if you manage your own numerical data it is recommended to use an optimized file format such as HDF5 to reduce data load times Various libraries such as H5Py PyTables and pandas provides a Python interface for reading and writing data in that format

37 Computing with scikitlearn

371 Strategies to scale computationally bigger data

For some applications the amount of examples features or both andor the speed at which they need to be processed are challenging for traditional approaches In these cases scikitlearn has a number of options you can consider to make your system scale

Scaling with instances using outofcore learning

Outofcore or “external memory” learning is a technique used to learn from data that cannot fit in a computer’s main memory RAM

Here is a sketch of a system designed to achieve this goal

1 a way to stream instances

2 a way to extract features from instances

3 an incremental algorithm

Streaming instances

Basically 1 may be a reader that yields instances from files on a hard drive a database from a network stream etc However details on how to achieve this are beyond the scope of this documentation

Extracting features

2 could be any relevant way to extract features among the different feature extraction methods supported by scikit learn However when working with data that needs vectorization and where the set of features or values is not known in advance one should take explicit care A good example is text classification where unknown terms are likely to be found during training It is possible to use a stateful vectorizer if making multiple passes over the data is reasonable from an application point of view Otherwise one can turn up the difficulty by using a stateless feature extractor Currently the preferred way to do this is to use the socalled hashing trick as implemented by sklearn featureextractionFeatureHasher for datasets with categorical variables represented as list of Python dicts orsklearnfeatureextractiontextHashingVectorizer for text documents

Incremental learning

Finally for 3 we have a number of options inside scikitlearn Although not all algorithms can learn incrementally ie without seeing all the instances at once all estimators implementing the partialfit API are candidates

Actually the ability to learn incrementally from a minibatch of instances sometimes called “online learning” is key to outofcore learning as it guarantees that at any given time there will be only a small amount of instances in the

main memory Choosing a good size for the minibatch that balances relevancy and memory footprint could involve some tuning1

Here is a list of incremental estimators for different tasks

•Classification
–sklearnnaivebayesMultinomialNB
–sklearnnaivebayesBernoulliNB
–sklearnlinearmodelPerceptron
–sklearnlinearmodelSGDClassifier
–sklearnlinearmodelPassiveAggressiveClassifier
–sklearnneuralnetworkMLPClassifier
•Regression
–sklearnlinearmodelSGDRegressor
–sklearnlinearmodelPassiveAggressiveRegressor
–sklearnneuralnetworkMLPRegressor
•Clustering
–sklearnclusterMiniBatchKMeans
–sklearnclusterBirch
•Decomposition feature Extraction
–sklearndecompositionMiniBatchDictionaryLearning
–sklearndecompositionIncrementalPCA
–sklearndecompositionLatentDirichletAllocation
•Preprocessing
–sklearnpreprocessingStandardScaler
–sklearnpreprocessingMinMaxScaler
–sklearnpreprocessingMaxAbsScaler

For classification a somewhat important thing to note is that although a stateless feature extraction routine may be able to cope with newunseen attributes the incremental learner itself may be unable to cope with newunseen targets classes In this case you have to pass all the possible classes to the first partialfit call using the classes parameter

Another aspect to consider when choosing a proper algorithm is that not all of them put the same importance on each example over time Namely the Perceptron is still sensitive to badly labeled examples even after many examples whereas the SGDandPassiveAggressive families are more robust to this kind of artifacts Conversely the latter also tend to give less importance to remarkably different yet properly labeled examples when they come late in the stream as their learning rate decreases over time

1Depending on the algorithm the minibatch size can influence results or not SGD PassiveAggressive and discrete NaiveBayes are truly online and are not affected by batch size Conversely MiniBatchKMeans convergence rate is affected by the batch size Also its memory footprint can vary dramatically with batch size

Examples
Finally we have a fullfledged example of Outofcore classification of text documents It is aimed at providing a starting point for people wanting to build outofcore learning systems and demonstrates most of the notions discussed above
Furthermore it also shows the evolution of the performance of different algorithms with the number of processed examples
Now looking at the computation time of the different parts we see that the vectorization is much more expensive than learning itself From the different algorithms MultinomialNB is the most expensive but its overhead can be mitigated by increasing the size of the minibatches exercise change minibatchsize to 100 and 10000 in the program and compare

Notes
372 Computational Performance
For some applications the performance mainly latency and throughput at prediction time of estimators is crucial It may also be of interest to consider the training throughput but this is often less important in a production setup where it often takes place offline
We will review here the orders of magnitude you can expect from a number of scikitlearn estimators in different contexts and provide some tips and tricks for overcoming performance bottlenecks
Prediction latency is measured as the elapsed time necessary to make a prediction eg in microseconds Latency is often viewed as a distribution and operations engineers often focus on the latency at a given percentile of this distribution eg the 90 percentile
Prediction throughput is defined as the number of predictions the software can deliver in a given amount of time eg in predictions per second
An important aspect of performance optimization is also that it can hurt prediction accuracy Indeed simpler models eg linear instead of nonlinear or with fewer parameters often run faster but are not always able to take into account the same exact properties of the data as more complex ones
Prediction Latency
One of the most straightforward concerns one may have when usingchoosing a machine learning toolkit is the latency at which predictions can be made in a production environment
The main factors that influence the prediction latency are
1 Number of features

A last major parameter is also the possibility to do predictions in bulk or oneatatime mode

Bulk versus Atomic mode

In general doing predictions in bulk many instances at the same time is more efficient for a number of reasons branching predictability CPU cache linear algebra libraries optimizations etc Here we see on a setting with few features that independently of estimator choice the bulk mode is always faster and for some of them by 1 to 2 orders of magnitude

To benchmark different estimators for your case you can simply change the nfeatures parameter in this example
Prediction Latency This should give you an estimate of the order of magnitude of the prediction latency
Configuring Scikitlearn for reduced validation overhead
Scikitlearn does some validation on data that increases the overhead per call to predict and similar functions
In particular checking that features are finite not NaN or infinite involves a full pass over the data If you en
sure that your data is acceptable you may suppress checking for finiteness by setting the environment variable
SKLEARNASSUMEFINITE to a nonempty string before importing scikitlearn or configure it in Python with
sklearnsetconfig For more control than these global settings a configcontext allows you to set this
configuration within a specified context
```
 import sklearn
 with sklearnconfigcontextassumefinite True
 pass  do learningprediction here with reduced validation
```
Note that this will affect all uses of sklearnutilsassertallfinite within the context
Influence of the Number of Features
Obviously when the number of features increases so does the memory consumption of each example Indeed for a
matrix of □instances with □features the space complexity is in □□□ From a computing perspective it also
means that the number of basic operations eg multiplications for vectormatrix products in linear models increases
too Here is a graph of the evolution of the prediction latency with the number of features

Overall you can expect the prediction time to increase at least linearly with the number of features nonlinear cases can happen depending on the global memory footprint and estimator

Influence of the Input Data Representation

Scipy provides sparse matrix data structures which are optimized for storing sparse data The main feature of sparse formats is that you don’t store zeros so if your data is sparse then you use much less memory A nonzero value in a sparse CSR or CSC representation will only take on average one 32bit integer position the 64 bit floating point value an additional 32bit per row or column in the matrix Using sparse input on a dense or sparse linear model can speedup prediction by quite a bit as only the non zero valued features impact the dot product and thus the model predictions Hence if you have 100 non zeros in 1e6 dimensional space you only need 100 multiply and add operation instead of 1e6

Calculation over a dense representation however may leverage highly optimised vector operations and multithreading in BLAS and tends to result in fewer CPU cache misses So the sparsity should typically be quite high 10 nonzeros max to be checked depending on the hardware for the sparse input representation to be faster than the dense input representation on a machine with many CPUs and an optimized BLAS implementation

Here is sample code to test the sparsity of your input

```
defsparsityratioX
return10  npcountnonzeroX  floatXshape0 Xshape1
printinput sparsity ratio sparsityratioX
```

As a rule of thumb you can consider that if the sparsity ratio is greater than 90 you can probably benefit from sparse formats Check Scipy’s sparse matrix formats documentation for more information on how to build or convert your data to sparse matrix formats Most of the time the CSR andCSC formats work best

Influence of the Model Complexity
Generally speaking when model complexity increases predictive power and latency are supposed to increase In creasing predictive power is usually interesting but for many applications we would better not increase prediction latency too much We will now review this idea for different families of supervised models
Forsklearnlinearmodel eg Lasso ElasticNet SGDClassifierRegressor Ridge RidgeClassifier PassiveAggressiveClassifierRegressor LinearSVC LogisticRegression the decision function that is applied at prediction time is the same a dot product so latency should be equivalent
Here is an example using sklearnlinearmodelstochasticgradientSGDClassifier with the elasticnet penalty The regularization strength is globally controlled by the alpha parameter With a sufficiently highalpha one can then increase the l1ratio parameter of elasticnet to enforce various levels of sparsity in the model coefficients Higher sparsity here is interpreted as less model complexity as we need fewer coefficients to describe it fully Of course sparsity influences in turn the prediction time as the sparse dotproduct takes time roughly proportional to the number of nonzero coefficients
For thesklearnsvm family of algorithms with a nonlinear kernel the latency is tied to the number of support vectors the fewer the faster Latency and throughput should asymptotically grow linearly with the number of support vectors in a SVC or SVR model The kernel will also influence the latency as it is used to compute the projection of the input vector once per support vector In the following graph the nuparameter of sklearnsvm classesNuSVR was used to influence the number of support vectors

Forsklearnensemble of trees eg RandomForest GBT ExtraTrees etc the number of trees and their depth play the most important role Latency and throughput should scale linearly with the number of trees In this case we used directly the nestimators parameter of sklearnensemblegradientboosting GradientBoostingRegressor

In any case be warned that decreasing model complexity can hurt accuracy as mentioned above For instance a non linearly separable problem can be handled with a speedy linear model but prediction power will very likely suffer in the process

Feature Extraction Latency
Most scikitlearn models are usually pretty fast as they are implemented either with compiled Cython extensions or optimized computing libraries On the other hand in many real world applications the feature extraction process ie turning raw data like database rows or network packets into numpy arrays governs the overall prediction time For example on the Reuters text classification task the whole preparation reading and parsing SGML files tokenizing the text and hashing it into a common vector space is taking 100 to 500 times more time than the actual prediction code depending on the chosen model
In many cases it is thus recommended to carefully time and profile your feature extraction code as it may be a good place to start optimizing when your overall latency is too slow for your application
Prediction Throughput
Another important metric to care about when sizing production systems is the throughput ie the number of predictions you can make in a given amount of time Here is a benchmark from the Prediction Latency example that measures this quantity for a number of estimators on synthetic data

These throughputs are achieved on a single process An obvious way to increase the throughput of your application is to spawn additional instances usually processes in Python because of the GIL that share the same model One might also add machines to spread the load A detailed explanation on how to achieve this is beyond the scope of this documentation though

Tips and Tricks

Linear algebra libraries

As scikitlearn relies heavily on NumpyScipy and linear algebra in general it makes sense to take explicit care of the versions of these libraries Basically you ought to make sure that Numpy is built using an optimized BLAS LAPACK library

Not all models benefit from optimized BLAS and Lapack implementations For instance models based on random ized decision trees typically do not rely on BLAS calls in their inner loops nor do kernel SVMs SVCSVRNuSVC NuSVR On the other hand a linear model implemented with a BLAS DGEMM call via numpydot will typically benefit hugely from a tuned BLAS implementation and lead to orders of magnitude speedup over a nonoptimized BLAS

You can display the BLAS LAPACK implementation used by your NumPy SciPy scikitlearn install with the following commands

```
from numpydistutilssysteminfo import getinfo
printgetinfoblasopt
printgetinfolapackopt
```

Optimized BLAS LAPACK implementations include

• Atlas need hardware specific tuning by rebuilding on the target machine

• OpenBLAS
• MKL
• Apple Accelerate and vecLib frameworks OSX only
More information can be found on the Scipy install page and in this blog post from Daniel Nouri which has some nice step by step install instructions for Debian Ubuntu
Limiting Working Memory
Some calculations when implemented using standard numpy vectorized operations involve using a large amount of temporary memory This may potentially exhaust system memory Where computations can be performed in fixed memory chunks we attempt to do so and allow the user to hint at the maximum size of this working memory de faulting to 1GB using sklearnsetconfig orconfigcontext The following suggests to limit temporary working memory to 128 MiB
```
import sklearn
with sklearnconfigcontextworkingmemory128
pass  do chunked work here
```
An example of a chunked operation adhering to this setting is metricpairwisedistanceschunked which facilitates computing rowwise reductions of a pairwise distance matrix
Model Compression
Model compression in scikitlearn only concerns linear models for the moment In this context it means that we want to control the model sparsity ie the number of nonzero coordinates in the model vectors It is generally a good idea to combine model sparsity with sparse input data representation
Here is sample code that illustrates the use of the sparsify method
```
clf  SGDRegressorpenaltyelasticnet l1ratio025
clffitXtrain ytrainsparsify
clfpredictXtest
```
In this example we prefer the elasticnet penalty as it is often a good compromise between model compactness and prediction power One can also further tune the l1ratio parameter in combination with the regularization strengthalpha to control this tradeoff
A typical benchmark on synthetic data yields a 30 decrease in latency when both the model and input are sparse with 0000024 and 0027400 nonzero coefficients ratio respectively Your mileage may vary depending on the sparsity and size of your data and model Furthermore sparsifying can be very useful to reduce the memory usage of predictive models deployed on production servers
Model Reshaping
Model reshaping consists in selecting only a portion of the available features to fit a model In other words if a model discards features during the learning phase we can then strip those from the input This has several benefits Firstly it reduces memory and therefore time overhead of the model itself It also allows to discard explicit feature selection components in a pipeline once we know which features to keep from a previous run Finally it can help reduce processing time and IO usage upstream in the data access and feature extraction layers by not collecting and building features that are discarded by the model For instance if the raw data come from a database it can make it possible to write simpler and faster queries or reduce IO usage by making the queries return lighter records At the

moment reshaping needs to be performed manually in scikitlearn In the case of sparse input particularly in CSR format it is generally sufficient to not generate the relevant features leaving their columns empty

373 Parallelism resource management and configuration

Parallel and distributed computing

Scikitlearn uses the joblib library to enable parallel computing inside its estimators See the joblib documentation for the switches to control parallel computing

Note that by default scikitlearn uses its embedded vendored version of joblib A configuration switch documented below controls this behavior

Configuration switches

Python runtime

sklearnsetconfig controls the following behaviors

assumefinite used to skip validation which enables faster computations but may lead to segmentation faults if the data contains NaNs

workingmemory the optimal size of temporary arrays used by some algoritms

Environment variables

These environment variables should be set before importing scikitlearn

SKLEARNSITEJOBLIB When this environment variable is set to a non zero value scikitlearn uses the site joblib rather than its vendored version Consequently joblib must be installed for scikitlearn to run Note that using the site joblib is at your own risks the versions of scikitlearn and joblib need to be compatible Currently joblib 011 is supported In addition dumps from joblibMemory might be incompatible and you might loose some caches and have to redownload some datasets Deprecated since version 021 As of version 021 this parameter has no effect vendored joblib was removed and site joblib is always used

SKLEARNASSUMEFINITE Sets the default value for the assumefinite argument of sklearnsetconfig

SKLEARNWORKINGMEMORY Sets the default value for the Limiting Working Memory argument ofsklearnsetconfig

SKLEARNSEED Sets the seed of the global random generator when running the tests for reproducibil ity

SKLEARNSKIPNETWORKTESTS When this environment variable is set to a non zero value the tests that need network access are skipped

CHAPTER
FOUR
GLOSSARY OF COMMON TERMS AND API ELEMENTS

This glossary hopes to definitively represent the tacit and explicit conventions applied in Scikitlearn and its API while providing a reference for users and contributors It aims to describe the concepts and either detail their corresponding API or link to other relevant parts of the documentation which do so By linking to glossary entries from the API Reference and User Guide we may minimize redundancy and inconsistency

We begin by listing general concepts and any that didn't fit elsewhere but more specific sets of related terms are listed below Class APIs and Estimator Types Target Types Methods Parameters Attributes Data and sample properties

41 General Concepts

1d

1d array Onedimensional array A NumPy array whose shape has length 1 A vector

2d

2d array Twodimensional array A NumPy array whose shape has length 2 Often represents a matrix

API Refers to both the specific interfaces for estimators implemented in Scikitlearn and the generalized conventions across types of estimators as described in this glossary and overviewed in the contributor documentation

The specific interfaces that constitute Scikitlearn's public API are largely documented in API Reference How ever we less formally consider anything as public API if none of the identifiers required to access it begins with We generally try to maintain backwards compatibility for all objects in the public API

Private API including functions modules and methods beginning are not assured to be stable

arraylike The most common data format for input to Scikitlearn estimators and functions arraylike is any type object for which numpyasarray will produce an array of appropriate shape usually 1 or 2dimensional of appropriate dtype usually numeric

This includes

• a numpy array
• a list of numbers
• a list of lengthk lists of numbers for some fixed length k
• apandasDataFrame with all columns numeric
• a numeric pandasSeries

It excludes

• asparse matrix
• an iterator

• a generator
Note that output from scikitlearn estimators and functions eg predictions should generally be arrays or sparse matrices or lists thereof as in multioutput treeDecisionTreeClassifier ‘spredictproba An estimator where predict returns a list or a pandasSeries is not valid
attribute
attributes We mostly use attribute to refer to how model information is stored on an estimator during fitting Any public attribute stored on an estimator instance is required to begin with an alphabetic character and end in a single underscore if it is set in fitorpartialfit These are what is documented under an estimator’s Attributes documentation The information stored in attributes is usually either sufficient statistics used for prediction or transformation transductive outputs such as labels orembedding or diagnostic data such as featureimportances Common attributes are listed below
A public attribute may have the same name as a constructor parameter with aappended This is used to store a validated or estimated version of the user’s input For example decompositionPCA is constructed with anncomponents parameter From this together with other parameters and the data PCA estimates the attributencomponents
Further private attributes used in predictiontransformationetc may also be set when fitting These begin with a single underscore and are not assured to be stable for public access
A public attribute on an estimator instance that does not end in an underscore should be the stored unmodified value of an init parameter of the same name Because of this equivalence these are documented under an estimator’s Parameters documentation
backwards compatibility We generally try to maintain backwards compatibility ie interfaces and behaviors may be extended but not changed or removed from release to release but this comes with some exceptions
Public API only The behaviour of objects accessed through private identifiers those beginning may be changed arbitrarily between versions
As documented We will generally assume that the users have adhered to the documented parameter types and ranges If the documentation asks for a list and the user gives a tuple we do not assure consistent behavior from version to version
Deprecation Behaviors may change following a deprecation period usually two releases long Warnings are issued using Python’s warnings module
Keyword arguments We may sometimes assume that all optional parameters other than X and y to fitand similar methods are passed as keyword arguments only and may be positionally reordered
Bug fixes and enhancements Bug fixes and – less often – enhancements may change the behavior of estimators including the predictions of an estimator trained on the same data and randomstate When this happens we attempt to note it clearly in the changelog
Serialization We make no assurances that pickling an estimator in one version will allow it to be unpickled to an equivalent model in the subsequent version For estimators in the sklearn package we issue a warning when this unpickling is attempted even if it may happen to work See Security maintainability limitations
utilsestimatorcheckscheckestimator We provide limited backwards compatibility assurances for the estimator checks we may add extra requirements on estimators tested with this function usually when these were informally assumed but not formally tested
Despite this informal contract with our users the software is provided as is as stated in the licence When a release inadvertently introduces changes that are not backwards compatible these are known as software regressions
callable A function class or an object which implements the call method anything that returns True when the argument of callable

categorical feature A categorical or nominal feature is one that has a finite set of discrete values across the pop
ulation of data These are commonly represented as columns of integers or strings Strings will be rejected
by most scikitlearn estimators and integers will be treated as ordinal or countvalued For the use with most
estimators categorical variables should be onehot encoded Notable exceptions include treebased models such
as random forests and gradient boosting models that often work better and faster with integercoded categor
ical variables OrdinalEncoder helps encoding stringvalued categorical features as ordinal integers and
OneHotEncoder can be used to onehot encode categorical features See also Encoding categorical features
and the categoricalencoding package for tools related to encoding categorical features
clone
cloned To copy an estimator instance and create a new one with identical parameters but without any fitted attributes
usingclone
Whenfit is called a metaestimator usually clones a wrapped estimator instance before fitting the cloned
instance Exceptions for legacy reasons include Pipeline andFeatureUnion
common tests This refers to the tests run on almost every estimator class in Scikitlearn to check they comply
with basic API conventions They are available for external use through utilsestimatorchecks
checkestimator with most of the implementation in sklearnutilsestimatorcheckspy
Note Some exceptions to the common testing regime are currently hardcoded into the library but we hope to
replace this by marking exceptional behaviours on the estimator using semantic estimator tags
deprecation We use deprecation to slowly violate our backwards compatibility assurances usually to to
• change the default value of a parameter or
• remove a parameter attribute method class etc
We will ordinarily issue a warning when a deprecated element is used although there may be limitations to this
For instance we will raise a warning when someone sets a parameter that has been deprecated but may not
when they access that parameter’s attribute on the estimator instance
See the Contributors’ Guide
dimensionality May be used to refer to the number of features ie nfeatures or columns in a 2d feature matrix
Dimensions are however also used to refer to the length of a NumPy array’s shape distinguishing a 1d array
from a 2d matrix
docstring The embedded documentation for a module class function etc usually in code as a string at the beginning
of the object’s definition and accessible as the object’s doc attribute
We try to adhere to PEP257 and follow NumpyDoc conventions
double underscore
double underscore notation When specifying parameter names for nested estimators may be used to separate
between parent and child in some contexts The most common use is when setting parameters through a meta
estimator with setparams and hence in specifying a search grid in parameter search See parameter It is also
used inpipelinePipelinefit for passing sample properties to thefit methods of estimators in the
pipeline
dtype
data type NumPy arrays assume a homogeneous data type throughout available in the dtype attribute of an array
or sparse matrix We generally assume simple data types for scikitlearn data float or integer We may support
object or string data types for arrays before encoding or vectorizing Our estimators do not work with struct
arrays for instance
TODO Mention efficiency and precision issues casting policy

duck typing We try to apply duck typing to determine how to handle some input values eg checking whether a given estimator is a classifier That is we avoid using isinstance where possible and rely on the presence or absence of attributes to determine an object's behaviour Some nuance is required when following this approach

• For some estimators an attribute may only be available once it is fitted For instance we cannot a priori determine if predictproba is available in a grid search where the grid includes alternating between a probabilistic and a nonprobabilistic predictor in the final step of the pipeline In the following we can only determine if clf is probabilistic after fitting it on some data

```
 from sklearnmodelselection import GridSearchCV
 from sklearnlinearmodel import SGDClassifier
clf  GridSearchCVSGDClassifier
 paramgridloss log hinge
```

This means that we can only check for ducktyped attributes after fitting and that we must be careful to make metaestimators only present attributes according to the state of the underlying estimator after fitting

• Checking if an attribute is present using hasattr is in general just as expensive as getting the attribute getattr or dot notation In some cases getting the attribute may indeed be expensive eg for some implementations of featureimportances which may suggest this is an API design flaw So code which doeshasattr followed by getattr should be avoided getattr within a tryexcept block is pre ferred

• For determining some aspects of an estimator's expectations or support for some feature we use estimator tags instead of duck typing

early stopping This consists in stopping an iterative optimization method before the convergence of the training loss to avoid overfitting This is generally done by monitoring the generalization score on a validation set When available it is activated through the parameter earlystopping or by setting a positive niternochange

estimator instance We sometimes use this terminology to distinguish an estimator class from a constructed instance For example in the following cls is an estimator class while est1 andest2 are instances

```
cls  RandomForestClassifier
est1  cls
est2  RandomForestClassifier
```

examples We try to give examples of basic usage for most functions and classes in the API

• as doctests in their docstrings ie within the sklearn library code itself

• as examples in the example gallery rendered using sphinxgallery from scripts in the examples direc tory exemplifying key features or parameters of the estimatorfunction These should also be referenced from the User Guide

• sometimes in the User Guide built from doc alongside a technical description of the estimator

evaluation metric

evaluation metrics Evaluation metrics give a measure of how well a model performs We may use this term specif ically to refer to the functions in metrics disregarding metricspairwise as distinct from the score method and the scoring API used in cross validation See Model evaluation quantifying the quality of predic tions

These functions usually accept a ground truth or the raw data where the metric evaluates clustering without a ground truth and a prediction be it the output of predict ypred of predictproba yproba or of an arbitrary score function including decisionfunction yscore Functions are usually named to end with score if a greater score indicates a better model and loss if a lesser score indicates a better model This diversity of interface motivates the scoring API

Note that some estimators can calculate metrics that are not included in metrics and are estimatorspecific notably model likelihoods

estimator tags A proposed feature eg 8022 by which the capabilities of an estimator are described through a set of semantic tags This would enable some runtime behaviors based on estimator inspection but it also allows each estimator to be tested for appropriate invariances while being excepted from other common tests
Some aspects of estimator tags are currently determined through the duck typing of methods like predictproba and through some special attributes on estimator objects

estimatortype This stringvalued attribute identifies an estimator as being a classifier regressor etc It is set by mixins such as baseClassifierMixin but needs to be more explicitly adopted on a meta estimator Its value should usually be checked by way of a helper such as baseisclassifier

pairwise This boolean attribute indicates whether the data X passed tofit and similar methods consists of pairwise measures over samples rather than a feature representation for each sample It is usually True where an estimator has a metric oraffinity orkernel parameter with value 'precomputed'
Its primary purpose is that when a metaestimator extracts a subsample of data intended for a pairwise estimator the data needs to be indexed on both axes while other data is indexed only on the first axis

feature
features

feature vector In the abstract a feature is a function in its mathematical sense mapping a sampled object to a nu meric or categorical quantity "Feature" is also commonly used to refer to these quantities being the individual elements of a vector representing a sample In a data matrix features are represented as columns each column contains the result of applying a feature function to a set of samples
Elsewhere features are known as attributes predictors regressors or independent variables
Nearly all estimators in scikitlearn assume that features are numeric finite and not missing even when they have semantically distinct domains and distributions categorical ordinal countvalued realvalued interval
See also categorical feature andmissing values

nfeatures indicates the number of features in a dataset

fitting Calling fitorfittransform fitpredict etc on an estimator

fitted The state of an estimator after fitting
There is no conventional procedure for checking if an estimator is fitted However an estimator that is not fitted
• should raise exceptionsNotFittedError when a prediction method predict transform etc is called utilsvalidationcheckisfitted is used internally for this purpose
• should not have any attributes beginning with an alphabetic character and ending with an underscore
Note that a descriptor for the attribute may still be present on the class but hasattr should return False

function We provide ad hoc function interfaces for many algorithms while estimator classes provide a more consis tent interface
In particular Scikitlearn may provide a function interface that fits a model to some data and returns the learnt model parameters as in linearmodelenetpath For transductive models this also returns the em bedding or cluster labels as in manifoldspectralembedding orclusterdbscan Many prepro cessing transformers also provide a function interface akin to calling fittransform as inpreprocessing maxabsscale Users should be careful to avoid data leakage when making use of these fittransform equivalent functions
We do not have a strict policy about when to or when not to provide function forms of estimators but maintainers should consider consistency with existing interfaces and whether providing a function would lead users astray from best practices as regards data leakage etc

gallery Seeexamples
hyperparameter
hyperparameter Seeparameter
impute
imputation Most machine learning algorithms require that their inputs have no missing values and will not work if this requirement is violated Algorithms that attempt to fill in or impute missing values are referred to as imputation algorithms
indexable Anarraylike sparse matrix pandas DataFrame or sequence usually a list
induction
inductive Inductive contrasted with transductive machine learning builds a model of some data that can then be applied to new instances Most estimators in Scikitlearn are inductive having predict andor transform methods
joblib A Python library httpsjoblibreadthedocsio used in Scikitlearn to facilite simple parallelism and caching Joblib is oriented towards efficiently working with numpy arrays such as through use of memory mapping See Parallel and distributed computing for more information
label indicator matrix
multilabel indicator matrix
multilabel indicator matrices The format used to represent multilabel data where each row of a 2d array or sparse matrix corresponds to a sample each column corresponds to a class and each element is 1 if the sample is labeled with the class and 0 if not
leakage
data leakage A problem in cross validation where generalization performance can be overestimated since knowl edge of the test data was inadvertently included in training a model This is a risk for instance when applying atransformer to the entirety of a dataset rather than each training portion in a cross validation split
We aim to provide interfaces such as pipeline andmodelselection that shield the user from data leakage
memmapping
memory map
memory mapping A memory efficiency strategy that keeps data on disk rather than copying it into main memory Memory maps can be created for arrays that can be read written or both using numpymemmap When using joblib to parallelize operations in Scikitlearn it may automatically memmap large arrays to reduce memory duplication overhead in multiprocessing
missing values Most Scikitlearn estimators do not work with missing values When they do eg in impute SimpleImputer NaN is the preferred representation of missing values in float arrays If the array has integer dtype NaN cannot be represented For this reason we support specifying another missingvalues value when imputation or learning can be performed in integer space Unlabeled data is a special case of missing values in the target
nfeatures The number of features
noutputs The number of outputs in the target
nsamples The number of samples
ntargets Synonym for noutputs
narrative docs

narrative documentation An alias for User Guide ie documentation written in docmodules Unlike the API reference provided through docstrings the User Guide aims to
• group tools provided by Scikitlearn together thematically or in terms of usage
• motivate why someone would use each particular tool often through comparison
• provide both intuitive and technical descriptions of tools
• provide or link to examples of using key features of a tool
npA shorthand for Numpy due to the conventional import statement
import numpy as np
online learning Where a model is iteratively updated by receiving each batch of ground truth targets soon after making predictions on corresponding batch of data Intrinsically the model must be usable for prediction after each batch See partialfit
outofcore An efficiency strategy where not all the data is stored in main memory at once usually by performing learning on batches of data See partialfit
outputs Individual scalarcategorical variables per sample in the target For example in multilabel classification each possible label corresponds to a binary output Also called responses tasks ortargets See multiclass multioutput andcontinuous multioutput
pair A tuple of length two
parameter
parameters
param
params We mostly use parameter to refer to the aspects of an estimator that can be specified in its construction For examplemaxdepth andrandomstate are parameters of RandomForestClassifier Parameters to an estimator’s constructor are stored unmodified as attributes on the estimator instance and conventionally start with an alphabetic character and end with an alphanumeric character Each estimator’s constructor param eters are described in the estimator’s docstring
We do not use parameters in the statistical sense where parameters are values that specify a model and can be estimated from data What we call parameters might be what statisticians call hyperparameters to the model aspects for configuring model structure that are often not directly learnt from data However our parameters are also used to prescribe modeling operations that do not affect the learnt model such as njobs for controlling parallelism
When talking about the parameters of a metaestimator we may also be including the parameters of the estimators wrapped by the metaestimator Ordinarily these nested parameters are denoted by using adouble underscore to separate between the estimatorasparameter and its parameter Thus clf BaggingClassifierbaseestimatorDecisionTreeClassifiermaxdepth3 has a deep parameter baseestimatormaxdepth with value 3 which is accessible with clf baseestimatormaxdepth orclfgetparamsbaseestimatormaxdepth
The list of parameters and their current values can be retrieved from an estimator instance using its getparams method
Between construction and fitting parameters may be modified using setparams To enable this parameters are not ordinarily validated or altered when the estimator is constructed or when each parameter is set Parameter validation is performed when fitis called
Common parameters are listed below
pairwise metric

pairwise metrics In its broad sense a pairwise metric defines a function for measuring similarity or dissimilar
ity between two samples with each ordinarily represented as a feature vector We particularly provide im
plementations of distance metrics as well as improper metrics like Cosine Distance through metrics
pairwisedistances and of kernel functions a constrained class of similarity functions in metrics
pairwisekernels These can compute pairwise distance matrices that are symmetric and hence store data
redundantly
See also precomputed andmetric
Note that for most distance metrics we rely on implementations from scipyspatialdistance but may
reimplement for efficiency in our context The neighbors module also duplicates some metric implementa
tions for integration with efficient binary tree search data structures
pdA shorthand for Pandas due to the conventional import statement
import pandas as pd
precomputed Where algorithms rely on pairwise metrics and can be computed from pairwise metrics alone we
often allow the user to specify that the Xprovided is already in the pairwise dissimilarity space rather than
in a feature space That is when passed to fit it is a square symmetric matrix with each vector indicating
dissimilarity to every sample and when passed to predictiontransformation methods each row corresponds
to a testing sample and each column to a training sample
Use of precomputed X is usually indicated by setting a metric affinity orkernel parameter to the
string ‘precomputed’ An estimator should mark itself as being pairwise if this is the case
rectangular Data that can be represented as a matrix with samples on the first axis and a fixed finite set of features
on the second is called rectangular
This term excludes samples with nonvectorial structure such as text an image of arbitrary size a time series of
arbitrary length a set of vectors etc The purpose of a vectorizer is to produce rectangular forms of such data
sample
samples We usually use this term as a noun to indicate a single feature vector Elsewhere a sample is called an
instance data point or observation nsamples indicates the number of samples in a dataset being the
number of rows in a data array X
sample property
sample properties A sample property is data for each sample eg an array of length nsamples passed to an
estimator method or a similar function alongside but distinct from the features X and target y The most
prominent example is sampleweight see others at Data and sample properties
As of version 019 we do not have a consistent approach to handling sample properties and their routing in
metaestimators though afitparams parameter is often used
scikitlearncontrib A venue for publishing Scikitlearncompatible libraries that are broadly authorized by the
core developers and the contrib community but not maintained by the core developer team See https
scikitlearncontribgithubio
scikitlearn enhancement proposals
SLEP
SLEPs Changes to the API principles and changes to dependencies or supported versions happen via a SLEP and
follows the decisionmaking process outlined in Scikitlearn governance and decisionmaking For all votes
a proposal must have been made public and discussed before the vote Such proposal must be a consolidated
document in the form of a ‘ScikitLearn Enhancement Proposal’ SLEP rather than a long discussion on an
issue A SLEP must be submitted as a pullrequest to enhancement proposals using the SLEP template
semisupervised

semisupervised learning
semisupervised Learning where the expected prediction label or ground truth is only available for some samples provided as training data when fitting the model We conventionally apply the label 1tounlabeled samples in semisupervised classification
sparse matrix A representation of twodimensional numeric data that is more memory efficient the corresponding dense numpy array where almost all elements are zero We use the scipysparse framework which provides several underlying sparse data representations or formats Some formats are more efficient than others for particular tasks and when a particular format provides especial benefit we try to document this fact in Scikit learn parameter descriptions
Some sparse matrix formats notably CSR CSC COO and LIL distinguish between implicit andexplicit zeros Explicit zeros are stored ie they consume memory in a data array in the data structure while implicit zeros correspond to every element not otherwise defined in explicit storage
Two semantics for sparse matrices are used in Scikitlearn
matrix semantics The sparse matrix is interpreted as an array with implicit and explicit zeros being interpreted as the number 0 This is the interpretation most often adopted eg when sparse matrices are used for feature matrices or multilabel indicator matrices
graph semantics As withscipysparsecsgraph explicit zeros are interpreted as the number 0 but implicit zeros indicate a masked or absent value such as the absence of an edge between two ver tices of a graph where an explicit value indicates an edge’s weight This interpretation is adopted to represent connectivity in clustering in representations of nearest neighborhoods eg neighbors kneighborsgraph and for precomputed distance representation where only distances in the neigh borhood of each point are required
When working with sparse matrices we assume that it is sparse for a good reason and avoid writing code that densifies a userprovided sparse matrix instead maintaining sparsity or raising an error if not possible ie if an estimator does not cannot support sparse matrices
supervised
supervised learning Learning where the expected prediction label or ground truth is available for each sample when fitting the model provided as y This is the approach taken in a classifier orregressor among other estimators
target
targets Thedependent variable insupervised and semisupervised learning passed as yto an estimator’s fitmethod Also known as dependent variable outcome variable response variable ground truth orlabel Scikitlearn works with targets that have minimal structure a class from a finite set a finite realvalued number multiple classes or multiple numbers See Target Types
transduction
transductive A transductive contrasted with inductive machine learning method is designed to model a spe cific dataset but not to apply that model to unseen data Examples include manifoldTSNE cluster AgglomerativeClustering andneighborsLocalOutlierFactor
unlabeled
unlabeled data Samples with an unknown ground truth when fitting equivalently missing values in the target See alsosemisupervised andunsupervised learning
unsupervised
unsupervised learning Learning where the expected prediction label or ground truth is not available for each sample when fitting the model as in clusterers andoutlier detectors Unsupervised estimators ignore any y passed to fit

42 Class APIs and Estimator Types
classifier
classifiers Asupervised orsemisupervised predictor with a finite set of discrete possible output values
A classifier supports modeling some of binary multiclass multilabel ormulticlass multioutput targets Within scikitlearn all classifiers support multiclass classification defaulting to using a onevsrest strategy over the binary classification problem
Classifiers must store a classes attribute after fitting and usually inherit from baseClassifierMixin which sets their estimatortype attribute
A classifier can be distinguished from other estimators with isclassifier
A classifier must implement
•fit
•predict
•score
It may also be appropriate to implement decisionfunction predictproba andpredictlogproba
clusterer
clusterers Aunsupervised predictor with a finite set of discrete output values
A clusterer usually stores labels after fitting and must do so if it is transductive
A clusterer must implement
•fit
•fitpredict iftransductive
•predict ifinductive
density estimator TODO
estimator
estimators An object which manages the estimation and decoding of a model The model is estimated as a determin istic function of
•parameters provided in object construction or with setparams
• the global numpyrandom random state if the estimator's randomstate parameter is set to None and
• any data or sample properties passed to the most recent call to fitfittransform orfitpredict or data similarly passed in a sequence of calls to partialfit
The estimated model is stored in public and private attributes on the estimator instance facilitating decoding through prediction and transformation methods
Estimators must provide a fitmethod and should provide setparams andgetparams although these are usually provided by inheritance from baseBaseEstimator
The core functionality of some estimators may also be available as a function
feature extractor
feature extractors Atransformer which takes input where each sample is not represented as an arraylike object of fixed length and produces an arraylike object of features for each sample and thus a 2dimensional arraylike for a set of samples In other words it lossily maps a nonrectangular data representation into rectangular data

Feature extractors must implement at least
•fit
•transform
•getfeaturenames
metaestimator
metaestimators
metaestimator
metaestimators Anestimator which takes another estimator as a parameter Examples include pipeline
Pipeline modelselectionGridSearchCV featureselectionSelectFromModel and
ensembleBaggingClassifier
In a metaestimator's fitmethod any contained estimators should be cloned before they are fit although FIXME
Pipeline and FeatureUnion do not do this currently An exception to this is that an estimator may explic
itly document that it accepts a prefitted estimator eg using prefitTrue infeatureselection
SelectFromModel One known issue with this is that the prefitted estimator will lose its model if the
metaestimator is cloned A metaestimator should have fit called before prediction even if all contained
estimators are prefitted
In cases where a metaestimator's primary behaviors eg predict ortransform implementation are functions
of predictiontransformation methods of the provided base estimator or multiple base estimators a meta
estimator should provide at least the standard methods provided by the base estimator It may not be possible
to identify which methods are provided by the underlying estimator until the metaestimator has been fitted
see also duck typing for which utilsmetaestimatorsifdelegatehasmethod may help It
should also provide or modify the estimator tags andclasses attribute provided by the base estimator
Metaestimators should be careful to validate data as minimally as possible before passing it to an underlying
estimator This saves computation time and may for instance allow the underlying estimator to easily work
with data that is not rectangular
outlier detector
outlier detectors Anunsupervised binary predictor which models the distinction between core and outlying samples
Outlier detectors must implement
•fit
•fitpredict iftransductive
•predict ifinductive
Inductive outlier detectors may also implement decisionfunction to give a normalized inlier score where outliers
have score below 0 scoresamples may provide an unnormalized score per sample
predictor
predictors Anestimator supporting predict andor fitpredict This encompasses classifier regressor outlier detec
torandclusterer
In statistics "predictors" refers to features
regressor
regressors Asupervised orsemisupervised predictor with continuous output values
Regressors usually inherit from baseRegressorMixin which sets their estimatortype attribute
A regressor can be distinguished from other estimators with isregressor

A regressor must implement
•fit
•predict
•score
transformer
transformers An estimator supporting transform andor fittransform A purely transductive transformer such as manifoldTSNE may not implement transform
vectorizer
vectorizers Seefeature extractor
There are further APIs specifically related to a small family of estimators such as
crossvalidation splitter
CV splitter
crossvalidation generator A nonestimator family of classes used to split a dataset into a sequence of train and test portions see Crossvalidation evaluating estimator performance by providing split andgetnsplits meth ods Note that unlike estimators these do not have fitmethods and do not provide setparams orgetparams Parameter validation may be performed in init
crossvalidation estimator An estimator that has builtin crossvalidation capabilities to automatically select the best hyperparameters see the User Guide Some example of crossvalidation estimators are ElasticNetCV and LogisticRegressionCV Crossvalidation estimators are named EstimatorCV and tend to be roughly equivalent to GridSearchCVEstimator The advantage of using a crossvalidation estimator over the canonical Estimator class along with grid search is that they can take advantage of warmstarting by reusing precomputed results in the previous steps of the crossvalidation process This generally leads to speed improvements An exception is the RidgeCV class which can instead perform efficient LeaveOneOut CV
scorer A nonestimator callable object which evaluates an estimator on given test data returning a number Unlike evaluation metrics a greater returned number must correspond with a better score See The scoring parameter defining model evaluation rules
Further examples
•neighborsDistanceMetric
•gaussianprocesskernelsKernel
•treeCriterion
43 Target Types
binary A classification problem consisting of two classes A binary target may represented as for a multiclass problem but with only two labels A binary decision function is represented as a 1d array
Semantically one class is often considered the “positive” class Unless otherwise specified eg using poslabel inevaluation metrics we consider the class label with the greater value numerically or lexicographically as the positive class of labels 0 1 1 is the positive class of 1 2 2 is the positive class of ‘no’ ‘yes’ ‘yes’ is the positive class of ‘no’ ‘YES’ ‘no’ is the positive class This affects the output of decisionfunction for instance
Note that a dataset sampled from a multiclass yor a continuous ymay appear to be binary

typeoftarget will return ‘binary’ for binary input or a similar array with only a single class present
continuous A regression problem where each sample’s target is a finite floating point number represented as a 1dimensional array of floats or sometimes ints
typeoftarget will return ‘continuous’ for continuous input but if the data is all integers it will be identified as ‘multiclass’
continuous multioutput
multioutput continuous A regression problem where each sample’s target consists of noutputs outputs each one a finite floating point number for a fixed int noutputs 1 in a particular dataset
Continuous multioutput targets are represented as multiple continuous targets horizontally stacked into an array of shapensamples noutputs
typeoftarget will return ‘continuousmultioutput’ for continuous multioutput input but if the data is all integers it will be identified as ‘multiclassmultioutput’
multiclass A classification problem consisting of more than two classes A multiclass target may be represented as a 1dimensional array of strings or integers A 2d column vector of integers ie a single output in multioutput terms is also accepted
We do not officially support other orderable hashable objects as class labels even if estimators may happen to work when given classification targets of such type
For semisupervised classification unlabeled samples should have the special label 1 in y
Within sckitlearn all estimators supporting binary classification also support multiclass classification using OnevsRest by default
ApreprocessingLabelEncoder helps to canonicalize multiclass targets as integers
typeoftarget will return ‘multiclass’ for multiclass input The user may also want to handle ‘binary’ input identically to ‘multiclass’
multiclass multioutput
multioutput multiclass A classification problem where each sample’s target consists of noutputs outputs each a class label for a fixed int noutputs 1 in a particular dataset Each output has a fixed set of available classes and each sample is labelled with a class for each output An output may be binary or multiclass and in the case where all outputs are binary the target is multilabel
Multiclass multioutput targets are represented as multiple multiclass targets horizontally stacked into an array of shapensamples noutputs
XXX For simplicity we may not always support string class labels for multiclass multioutput and integer class labels should be used
multioutput provides estimators which estimate multioutput problems using multiple singleoutput estima tors This may not fully account for dependencies among the different outputs which methods natively handling the multioutput case eg decision trees nearest neighbors neural networks may do better
typeoftarget will return ‘multiclassmultioutput’ for multiclass multioutput input
multilabel Amulticlass multioutput target where each output is binary This may be represented as a 2d dense array or sparse matrix of integers such that each column is a separate binary target where positive labels are indicated with 1 and negative labels are usually 1 or 0 Sparse multilabel targets are not supported everywhere that dense multilabel targets are supported
Semantically a multilabel target can be thought of as a set of labels for each sample While not used inter nallypreprocessingMultiLabelBinarizer is provided as a utility to convert from a list of sets
representation to a 2d array or sparse matrix Onehot encoding a multiclass target with preprocessing LabelBinarizer turns it into a multilabel problem

typeoftarget will return ‘multilabelindicator’ for multilabel input whether sparse or dense
multioutput
multioutput A target where each sample has multiple classificationregression labels See multiclass multioutput
andcontinuous multioutput We do not currently support modelling mixed classification and regression targets
44 Methods
decisionfunction In a fitted classifier oroutlier detector predicts a “soft” score for each sample in relation
to each class rather than the “hard” categorical prediction produced by predict Its input is usually only some
observed data X
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
Output conventions
binary classification A 1dimensional array where values strictly greater than zero indicate the positive class
ie the last class in classes
multiclass classification A 2dimensional array where the rowwise argmaximum is the predicted class
Columns are ordered according to classes
multilabel classification Scikitlearn is inconsistent in its representation of multilabel decision functions
Some estimators represent it like multiclass multioutput ie a list of 2d arrays each with two columns
Others represent it with a single 2d array whose columns correspond to the individual binary classification
decisions The latter representation is ambiguously identical to the multiclass classification format though
its semantics differ it should be interpreted like in the binary case by thresholding at 0
TODO This gist higlights the use of the different formats for multilabel
multioutput classification A list of 2d arrays corresponding to each multiclass decision function
outlier detection A 1dimensional array where a value greater than or equal to zero indicates an inlier
fit Thefit method is provided on every estimator It usually takes some samplesXtargetsyif the model is
supervised and potentially other sample properties such as sampleweight It should
• clear any prior attributes stored on the estimator unless warmstart is used
• validate and interpret any parameters ideally raising an error if invalid
• validate the input data
• estimate and store model attributes from the estimated parameters and provided data and
• return the now fitted estimator to facilitate method chaining
Target Types describes possible formats for y
fitpredict Used especially for unsupervised transductive estimators this fits the model and returns the pre
dictions similar to predict on the training data In clusterers these predictions are also stored in the labels
attribute and the output of fitpredictX is usually equivalent to fitXpredictX The pa
rameters to fitpredict are the same as those to fit
fittransform A method on transformers which fits the estimator and returns the transformed training
data It takes parameters as in fitand its output should have the same shape as calling fitX
transformX There are nonetheless rare cases where fittransformX andfitX
transformX do not return the same value wherein training data needs to be handled differently due
to model blending in stacked ensembles for instance such cases should be clearly documented Transductive
transformers may also provide fittransform but not transform

One reason to implement fittransform is that performing fit andtransform separately would be less efficient than together baseTransformerMixin provides a default implementation providing a consis tent interface across transformers where fittransform is or is not specialised
Ininductive learning – where the goal is to learn a generalised model that can be applied to new data – users should be careful not to apply fittransform to the entirety of a dataset ie training and test data together before further modelling as this results in data leakage
getfeaturenames Primarily for feature extractors but also used for other transformers to provide string names for each column in the output of the estimator's transform method It outputs a list of strings and may take a list of strings as input corresponding to the names of input columns from which output column names can be generated By default input features are named x0 x1
getnsplits On a CV splitter not an estimator returns the number of elements one would get if iterating through the return value of split given the same parameters Takes the same parameters as split
getparams Gets all parameters and their values that can be set using setparams A parameter deep can be used when set to False to only return those parameters not including ie not due to indirection via contained estimators
Most estimators adopt the definition from baseBaseEstimator which simply adopts the parameters de fined forinit pipelinePipeline among others reimplements getparams to declare the estimators named in its steps parameters as themselves being parameters
partialfit Facilitates fitting an estimator in an online fashion Unlike fit repeatedly calling partialfit does not clear the model but updates it with respect to the data provided The portion of data provided to partialfit may be called a minibatch Each minibatch must be of consistent shape etc In iterative estimators partialfit often only performs a single iteration
partialfit may also be used for outofcore learning although usually limited to the case where learning can be performed online ie the model is usable after each partialfit and there is no separate processing needed to finalize the model clusterBirch introduces the convention that calling partialfitX will produce a model that is not finalized but the model can be finalized by calling partialfit ie without passing a further minibatch
Generally estimator parameters should not be modified between calls to partialfit although partialfit should validate them as well as the new minibatch of data In contrast warmstart is used to repeatedly fit the same estimator with the same data but varying parameters
Likefitpartialfit should return the estimator object
To clear the model a new estimator should be constructed for instance with baseclone
predict Makes a prediction for each sample usually only taking Xas input but see under regressor output con ventions below In a classifier orregressor this prediction is in the same target space used in fitting eg one of 'red' 'amber' 'green' if the yin fitting consisted of these strings Despite this even when ypassed to fit is a list or other arraylike the output of predict should always be an array or sparse matrix In a clusterer or outlier detector the prediction is an integer
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
Output conventions
classifier An array of shape nsamplesnsamples noutputs Multilabel data may be rep resented as a sparse matrix if a sparse matrix was used in fitting Each element should be one of the values in the classifier's classes attribute
clusterer An array of shape nsamples where each value is from 0 to nclusters 1 if the corre sponding sample is clustered and 1 if the sample is not clustered as in clusterdbscan
outlier detector An array of shape nsamples where each value is 1 for an outlier and 1 otherwise

regressor A numeric array of shape nsamples usually float64 Some regressors have extra options in
theirpredict method allowing them to return standard deviation returnstdTrue or covariance
returncovTrue relative to the predicted value In this case the return value is a tuple of arrays
corresponding to prediction mean std cov as required
predictlogproba The natural logarithm of the output of predictproba provided to facilitate numerical sta
bility
predictproba A method in classifiers andclusterers that are able to return probability estimates for each
classcluster Its input is usually only some observed data X
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
Output conventions are like those for decisionfunction except in the binary classification case where one
column is output for each class while decisionfunction outputs a 1d array For binary and multiclass
predictions each row should add to 1
Like other methods predictproba should only be present when the estimator can make probabilistic pre
dictions see duck typing This means that the presence of the method may depend on estimator parameters eg
inlinearmodelSGDClassifier or training data eg in modelselectionGridSearchCV
and may only appear after fitting
score A method on an estimator usually a predictor which evaluates its predictions on a given dataset and returns
a single numerical score A greater return value should indicate better predictions accuracy is used for classifiers
and R2 for regressors by default
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
Some estimators implement a custom estimatorspecific score function often the likelihood of the data under
the model
scoresamples TODO
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
setparams Available in any estimator takes keyword arguments corresponding to keys in getparams Each is
provided a new value to assign such that calling getparams aftersetparams will reflect the changed pa
rameters Most estimators use the implementation in baseBaseEstimator which handles nested parame
ters and otherwise sets the parameter as an attribute on the estimator The method is overridden in pipeline
Pipeline and related estimators
split On a CV splitter not an estimator this method accepts parameters Xygroups where all may be op
tional and returns an iterator over trainidx testidx pairs Each of traintestidx is a 1d integer
array with values from 0 from Xshape0 1 of any length such that no values appear in both some
trainidx and its corresponding testidx
transform In a transformer transforms the input usually only X into some transformed space conventionally
notated as Xt Output is an array or sparse matrix of length nsamples and with number of columns fixed after
fitting
If the estimator was not already fitted calling this method should raise a exceptionsNotFittedError
45 Parameters
These common parameter names specifically used in estimator construction see concept parameter sometimes also
appear as parameters of functions or nonestimator constructors
classweight Used to specify sample weights when fitting classifiers as a function of the target class Where
sampleweight is also supported and given it is multiplied by the classweight contribution Similarly

whereclassweight is used in a multioutput including multilabel tasks the weights are multiplied across outputs ie columns of y
By default all samples have equal weight such that classes are effectively weighted by their their prevalence in the training data This could be achieved explicitly with classweightlabel1 1 label2 1
for all class labels
More generally classweight is specified as a dict mapping class labels to weights classlabel weight such that each sample of the named class is given that weight
classweightbalanced can be used to give all classes equal weight by giving each sample a weight inversely related to its class's prevalence in the training data nsamples nclasses np bincounty Class weights will be used differently depending on the algorithm for linear models such as linear SVM or logistic regression the class weights will alter the loss function by weighting the loss of each sample by its class weight For treebased algorithms the class weights will be used for reweighting the splitting criterion Note however that this rebalancing does not take the weight of samples in each class into account
For multioutput classification a list of dicts is used to specify weights for each output For example for four class multilabel classification weights should be 0 1 1 1 0 1 1 5 0 1
1 1 0 1 1 1 instead of11 25 31 41
Theclassweight parameter is validated and interpreted with utilscomputeclassweight
cv Determines a cross validation splitting strategy as used in crossvalidation based routines cv is also available in estimators such as multioutputClassifierChain orcalibration CalibratedClassifierCV which use the predictions of one estimator as training data for another to not overfit the training supervision
Possible inputs for cvare usually
• An integer specifying the number of folds in Kfold cross validation Kfold will be stratified over classes if the estimator is a classifier determined by baseisclassifier and the targets may represent a binary or multiclass but not multioutput classification problem determined by utilsmulticlass typeoftarget
• Acrossvalidation splitter instance Refer to the User Guide for splitters available within Scikitlearn
• An iterable yielding traintest splits
With some exceptions especially where not using cross validation at all is an option the default is 3fold and will change to 5fold in version 022
cvvalues are validated and interpreted with utilscheckcv
kernel TODO
maxiter For estimators involving iterative optimization this determines the maximum number of itera tions to be performed in fit Ifmaxiter iterations are run without convergence a exceptions ConvergenceWarning should be raised Note that the interpretation of "a single iteration" is inconsistent across estimators some but not all use it to mean a single epoch ie a pass over every sample in the data FIXME perhaps we should have some common tests about the relationship between ConvergenceWarning and maxiter
memory Some estimators make use of joblibMemory to store partial solutions during fitting Thus when fit is called again those partial solutions have been memoized and can be reused
Amemory parameter can be specified as a string with a path to a directory or a joblibMemory instance or an object with a similar interface ie a cache method can be used
memory values are validated and interpreted with utilsvalidationcheckmemory

metric As a parameter this is the scheme for determining the distance between two data points See metrics pairwisedistances In practice for some algorithms an improper distance metric one that does not obey the triangle inequality such as Cosine Distance may be used
XXX hierarchical clustering uses affinity with this meaning
We also use metric to refer to evaluation metrics but avoid using this sense as a parameter name
ncomponents The number of features which a transformer should transform the input into See components for the special case of affine projection
niternochange Number of iterations with no improvement to wait before stopping the iterative procedure This is also known as a patience parameter It is typically used with early stopping to avoid stopping too early
njobs This is used to specify how many concurrent processesthreads should be used for parallelized routines Scikitlearn uses one processor for its processing by default although it also makes use of NumPy which may be configured to use a threaded numerical processor library like MKL see FAQ
njobs is an int specifying the maximum number of concurrently running jobs If set to 1 all CPUs are used If 1 is given no joblib level parallelism is used at all which is useful for debugging Even with njobs 1 parallelism may occur due to numerical processing libraries see FAQ For njobs below 1 ncpus 1 njobs are used Thus for njobs 2 all CPUs but one are used
njobsNone means unset it will generally be interpreted as njobs1 unless the current joblib Parallel backend context specifies otherwise
The use ofnjobs based parallelism in estimators varies
• Most often parallelism happens in fitting but sometimes parallelism happens in prediction eg in random forests
• Some parallelism uses a multithreading backend by default some a multiprocessing backend It is pos sible to override the default backend by using sklearnutilsparallelbackend
• Whether parallel processing is helpful at improving runtime depends on many factors and it’s usually a good idea to experiment rather than assuming that increasing the number of jobs is always a good thing It can be highly detrimental to performance to run multiple copies of some estimators or functions in parallel
Nested uses of njobs based parallelism with the same backend will result in an exception So GridSearchCVOneVsRestClassifierSVC njobs2 njobs2 won’t work
Whennjobs is not 1 the estimator being parallelized must be picklable This means for instance that lambdas cannot be used as estimator parameters
randomstate Whenever randomization is part of a Scikitlearn algorithm a randomstate parameter may be provided to control the random number generator used Note that the mere presence of randomstate doesn’t mean that randomization is always used as it may be dependent on another parameter eg shuffle being set
randomstate ’s value may be
None default Use the global random state from numpyrandom
An integer Use a new random number generator seeded by the given integer To make a randomized al gorithm deterministic ie running it multiple times will produce the same result an arbitrary integer randomstate can be used However it may be worthwhile checking that your results are stable across a number of different distinct random seeds Popular integer random seeds are 0 and 42
AnumpyrandomRandomState instance Use the provided random state only affecting other users of the same random state instance Calling fit multiple times will reuse the same instance and will produce different results

utilscheckrandomstate is used internally to validate the input randomstate and return a RandomState instance

scoring Specifies the score function to be maximized usually by cross validation or – in some cases – multiple score functions to be reported The score function can be a string accepted by metricsgetscorer or a callable scorer not to be confused with an evaluation metric as the latter have a more diverse API scoring may also be set to None in which case the estimator's score method is used See The scoring parameter defining model evaluation rules in the User Guide

Where multiple metrics can be evaluated scoring may be given either as a list of unique strings or a dict with names as keys and callables as values Note that this does notspecify which score function is to be maximised and another parameter such as refit may be used for this purpose

Thescoring parameter is validated and interpreted using metricscheckscoring

verbose Logging is not handled very consistently in Scikitlearn at present but when it is provided as an option theverbose parameter is usually available to choose no logging set to False Any True value should enable some logging but larger integers eg above 10 may be needed for full verbosity Verbose logs are usually printed to Standard Output Estimators should not produce any output on Standard Output with the default verbose setting

warmstart When fitting an estimator repeatedly on the same dataset but for multiple parameter values such as to find the value maximizing performance as in grid search it may be possible to reuse aspects of the model learnt from the previous parameter value saving time When warmstart is true the existing fitted model attributes are used to initialise the new model in a subsequent call to fit

Note that this is only applicable for some models and some parameters and even some orders of parameter values For example warmstart may be used when building random forests to add more trees to the forest increasing nestimators but not to reduce their number

partialfit also retains the model between calls but differs with warmstart the parameters change and the data is moreorless constant across calls to fit withpartialfit the minibatch of data changes and model parameters stay fixed

There are cases where you want to use warmstart to fit on different but closely related data For exam ple one may initially fit to a subset of the data then finetune the parameter search on the full dataset For classification all data in a sequence of warmstart calls tofit must include samples from each class

46 Attributes

See concept attribute

classes A list of class labels known to the classifier mapping each label to a numerical index used in the model representation our output For instance the array output from predictproba has columns aligned with classes For multioutput classifiers classes should be a list of lists with one class listing for each output For each output the classes should be sorted numerically or lexicographically for strings classes and the mapping to indices is often managed with preprocessingLabelEncoder

components An affine transformation matrix of shape ncomponents nfeatures used in many lin eartransformers where ncomponents is the number of output features and nfeatures is the number of input features

See also components which is a similar attribute for linear predictors

coef The weightcoefficient matrix of a generalised linear model predictor of shapenfeatures for binary classification and singleoutput regression nclasses nfeatures for multiclass classification and ntargets nfeatures for multioutput regression Note this does not include the intercept or bias term which is stored in intercept

When available featureimportances is not usually provided as well but can be calculated as the norm
of each feature’s entry in coef
See also components which is a similar attribute for linear transformers
embedding An embedding of the training data in manifold learning estimators with shape nsamples
ncomponents identical to the output of fittransform See also labels
niter The number of iterations actually performed when fitting an iterative estimator that may stop upon con
vergence See also maxiter
featureimportances A vector of shape nfeatures available in some predictors to provide a relative
measure of the importance of each feature in the predictions of the model
labels A vector containing a cluster label for each sample of the training data in clusterers identical to the output
offitpredict See also embedding
47 Data and sample properties
See concept sample property
groups Used in cross validation routines to identify samples which are correlated Each value is an identifier such
that in a supporting CV splitter samples from some groups value may not appear in both a training set and
its corresponding test set See Crossvalidation iterators for grouped data
sampleweight A relative weight for each sample Intuitively if all weights are integers a weighted model or
score should be equivalent to that calculated when repeating the sample the number of times specified in the
weight Weights may be specified as floats so that sample weights are usually equivalent up to a constant
positive scaling factor
FIXME Is this interpretation always the case in practice We have no common tests
Some estimators such as decision trees support negative weights FIXME This feature or its absence may not
be tested or documented in many estimators
This is not entirely the case where other parameters of the model consider the number of samples in a region
as withminsamples inclusterDBSCAN In this case a count of samples becomes to a sum of their
weights
In classification sample weights can also be specified as a function of class with the classweight estimator
parameter
XDenotes data that is observed at training and prediction time used as independent variables in learning The
notation is uppercase to denote that it is ordinarily a matrix see rectangular When a matrix each sample may
be represented by a feature vector or a vector of precomputed dissimilarity with each training sample Xmay
also not be a matrix and may require a feature extractor or apairwise metric to turn it into one before learning
a model
Xt Shorthand for “transformed X”
y
YDenotes data that may be observed at training time as the dependent variable in learning but which is unavailable
at prediction time and is usually the target of prediction The notation may be uppercase to denote that it is
a matrix representing multioutput targets for instance but usually we use yand sometimes do so even when
multiple outputs are assumed

512 Isotonic Regression
An illustration of the isotonic regression on generated data The isotonic regression finds a nondecreasing approx imation of a function while minimizing the mean squared error on the training data The benefit of such a model is that it does not assume any form for the target function such as linearity For comparison a linear regression is also presented

514 Multilabel classification
This example simulates a multilabel document classification problem The dataset is generated randomly based on the following process
- pick the number of labels n Poissonnlabels
- n times choose a class c c Multinomialtheta
- pick the document length k Poissonlength
- k times choose a word w Multinomialthetac

In the above process rejection sampling is used to make sure that n is more than 2 and that the document length is never zero Likewise we reject classes which have already been chosen The documents that are assigned to both classes are plotted surrounded by two colored circles
The classification is performed by projecting to the first two principal components found by PCA and CCA for visual isation purposes followed by using the sklearnmulticlassOneVsRestClassifier metaclassifier using two SVCs with linear kernels to learn a discriminative model for each class Note that PCA is used to perform an unsupervised dimensionality reduction while CCA is used to perform a supervised one
Note in the plot “unlabeled samples” does not mean that we don’t know the labels as in semisupervised learning but that the samples simply do nothave a label

515 Comparing anomaly detection algorithms for outlier detection on toy datasets
This example shows characteristics of different anomaly detection algorithms on 2D datasets Datasets contain one or two modes regions of high density to illustrate the ability of algorithms to cope with multimodal data
For each dataset 15 of samples are generated as random uniform noise This proportion is the value given to the nu parameter of the OneClassSVM and the contamination parameter of the other outlier detection algorithms Decision boundaries between inliers and outliers are displayed in black except for Local Outlier Factor LOF as it has no predict method to be applied on new data when it is used for outlier detection
ThesklearnsvmOneClassSVM is known to be sensitive to outliers and thus does not perform very well for outlier detection This estimator is best suited for novelty detection when the training set is not contaminated by outliers That said outlier detection in highdimension or without any assumptions on the distribution of the inlying data is very challenging and a Oneclass SVM might give useful results in these situations depending on the value of its hyperparameters
sklearncovarianceEllipticEnvelope assumes the data is Gaussian and learns an ellipse It thus de grades when the data is not unimodal Notice however that this estimator is robust to outliers
sklearnensembleIsolationForest andsklearnneighborsLocalOutlierFactor seem to perform reasonably well for multimodal data sets The advantage of sklearnneighbors LocalOutlierFactor over the other estimators is shown for the third data set where the two modes have different densities This advantage is explained by the local aspect of LOF meaning that it only compares the score of abnor mality of one sample with the scores of its neighbors
Finally for the last data set it is hard to say that one sample is more abnormal than another sample as they are uniformly distributed in a hypercube Except for the sklearnsvmOneClassSVM which overfits a little all estimators present decent solutions for this situation In such a case it would be wise to look more closely at the scores of abnormality of the samples as a good estimator should assign similar scores to all the samples
While these examples give some intuition about the algorithms this intuition might not apply to very high dimensional data
Finally note that parameters of the models have been here handpicked but that in practice they need to be adjusted In the absence of labelled data the problem is completely unsupervised so model selection can be a challenge

516 The JohnsonLindenstrauss bound for embedding with random projections
The JohnsonLindenstrauss lemma states that any high dimensional dataset can be randomly projected into a lower dimensional Euclidean space while controlling the distortion in the pairwise distances
Theoretical bounds
The distortion introduced by a random projection pis asserted by the fact that pis defining an epsembedding with good probability as defined by
1−□□□‖□−□‖2‖□□−□□‖21 □□□‖□−□‖2
Where u and v are any rows taken from a dataset of shape nsamples nfeatures and p is a projection by a random Gaussian N0 1 matrix with shape ncomponents nfeatures or a sparse Achlioptas matrix
The minimum number of components to guarantees the epsembedding is given by
□□□□□□□□□□□ 4□□□□□□□□□□□ □□□22−□□□33
694 Chapter 5 Examples

The first plot shows that with an increasing number of samples nsamples the minimal number of dimensions ncomponents increased logarithmically in order to guarantee an epsembedding
The second plot shows that an increase of the admissible distortion eps allows to reduce drastically the minimal number of dimensions ncomponents for a given number of samples nsamples
Empirical validation
We validate the above bounds on the digits dataset or on the 20 newsgroups text document TFIDF word frequencies dataset
• for the digits dataset some 8x8 gray level pixels data for 500 handwritten digits pictures are randomly projected to spaces for various larger number of dimensions ncomponents
• for the 20 newsgroups dataset some 500 documents with 100k features in total are projected using a sparse random matrix to smaller euclidean spaces with various values for the target number of dimensions ncomponents
The default dataset is the digits dataset To run the example on the twenty newsgroups dataset pass the –twenty newsgroups command line argument to this script
For each value of ncomponents we plot
• 2D distribution of sample pairs with pairwise distances in original and projected spaces as x and y axis respec tively
• 1D histogram of the ratio of those distances projected original
We can see that for low values of ncomponents the distribution is wide with many distorted pairs and a skewed distribution due to the hard limit of zero ratio on the left as distances are always positives while for larger values of ncomponents the distortion is controlled and the distances are well preserved by the random projection
Remarks
According to the JL lemma projecting 500 samples without too much distortion will require at least several thousands dimensions irrespective of the number of features of the original dataset
Hence using random projections on the digits dataset which only has 64 features in the input space does not make sense it does not allow for dimensionality reduction in this case
On the twenty newsgroups on the other hand the dimensionality can be decreased from 56436 down to 10000 while reasonably preserving pairwise distances

scikitlearn user guide Release 0213
517 Comparison of kernel ridge regression and SVR
Both kernel ridge regression KRR and SVR learn a nonlinear function by employing the kernel trick ie they learn a linear function in the space induced by the respective kernel which corresponds to a nonlinear function in the original space They differ in the loss functions ridge versus epsiloninsensitive loss In contrast to SVR fitting a KRR can be done in closedform and is typically faster for mediumsized datasets On the other hand the learned model is nonsparse and thus slower than SVR at predictiontime
This example illustrates both methods on an artificial dataset which consists of a sinusoidal target function and strong noise added to every fifth datapoint The first figure compares the learned model of KRR and SVR when both com plexityregularization and bandwidth of the RBF kernel are optimized using gridsearch The learned functions are very similar however fitting KRR is approx seven times faster than fitting SVR both with gridsearch However prediction of 100000 target values is more than tree times faster with SVR since it has learned a sparse model using only approx 13 of the 100 training datapoints as support vectors
The next figure compares the time for fitting and prediction of KRR and SVR for different sizes of the training set Fitting KRR is faster than SVR for medium sized training sets less than 1000 samples however for larger training sets SVR scales better With regard to prediction time SVR is faster than KRR for all sizes of the training set because of the learned sparse solution Note that the degree of sparsity and thus the prediction time depends on the parameters epsilon and C of the SVR

518 Explicit feature map approximation for RBF kernels
An example illustrating the approximation of the feature map of an RBF kernel
It shows how to use RBFSampler andNystroem to approximate the feature map of an RBF kernel for classification with an SVM on the digits dataset Results using a linear SVM in the original space a linear SVM using the approx imate mappings and using a kernelized SVM are compared Timings and accuracy for varying amounts of Monte Carlo samplings in the case of RBFSampler which uses random Fourier features and different sized subsets of the training set for Nystroem for the approximate mapping are shown
Please note that the dataset here is not large enough to show the benefits of kernel approximation as the exact SVM is still reasonably fast
Sampling more dimensions clearly leads to better classification results but comes at a greater cost This means there is a tradeoff between runtime and accuracy given by the parameter ncomponents Note that solving the Linear SVM and also the approximate kernel SVM could be greatly accelerated by using stochastic gradient descent via sklearnlinearmodelSGDClassifier This is not easily possible for the case of the kernelized SVM
The second plot visualized the decision surfaces of the RBF kernel SVM and the linear SVM with approximate kernel maps The plot shows decision surfaces of the classifiers projected onto the first two principal components of the data This visualization should be taken with a grain of salt since it is just an interesting slice through the decision surface in 64 dimensions In particular note that a datapoint represented as a dot does not necessarily be classified into the region it is lying in since it will not lie on the plane that the first two principal components span
The usage of RBFSampler andNystroem is described in detail in Kernel Approximation

521 Outlier detection on a real data set
This example illustrates the need for robust covariance estimation on a real data set It is useful both for outlier detection and for a better understanding of the data structure
We selected two sets of two variables from the Boston housing data set as an illustration of what kind of analysis can be done with several outlier detection tools For the purpose of visualization we are working with twodimensional examples but one should be aware that things are not so trivial in highdimension as it will be pointed out
In both examples below the main result is that the empirical covariance estimate as a nonrobust one is highly influenced by the heterogeneous structure of the observations Although the robust covariance estimate is able to focus on the main mode of the data distribution it sticks to the assumption that the data should be Gaussian distributed yielding some biased estimation of the data structure but yet accurate to some extent The OneClass SVM does not assume any parametric form of the data distribution and can therefore model the complex shape of the data much better
First example
The first example illustrates how robust covariance estimation can help concentrating on a relevant cluster when an other one exists Here many observations are confounded into one and break down the empirical covariance estima tion Of course some screening tools would have pointed out the presence of two clusters Support Vector Machines Gaussian Mixture Models univariate outlier detection But had it been a highdimensional example none of these could be applied that easily
Second example
The second example shows the ability of the Minimum Covariance Determinant robust estimator of covariance to concentrate on the main mode of the data distribution the location seems to be well estimated although the covariance is hard to estimate due to the bananashaped distribution Anyway we can get rid of some outlying observations The OneClass SVM is able to capture the real data structure but the difficulty is to adjust its kernel bandwidth parameter so as to obtain a good compromise between the shape of the data scatter matrix and the risk of overfitting the data

522 Compressive sensing tomography reconstruction with L1 prior Lasso
This example shows the reconstruction of an image from a set of parallel projections acquired along different angles
Such a dataset is acquired in computed tomography CT
Without any prior information on the sample the number of projections required to reconstruct the image is of the order of the linear size lof the image in pixels For simplicity we consider here a sparse image where only pixels on the boundary of objects have a nonzero value Such data could correspond for example to a cellular material
Note however that most images are sparse in a different basis such as the Haar wavelets Only l7 projections are acquired therefore it is necessary to use prior information available on the sample its sparsity this is an example of compressive sensing
The tomography projection operation is a linear transformation In addition to the datafidelity term corresponding to a linear regression we penalize the L1 norm of the image to account for its sparsity The resulting optimization problem is called the Lasso We use the class sklearnlinearmodelLasso that uses the coordinate descent algorithm Importantly this implementation is more computationally efficient on a sparse matrix than the projection operator used here
The reconstruction with L1 penalization gives a result with zero error all pixels are successfully labeled with 0 or 1 even if noise was added to the projections In comparison an L2 penalization sklearnlinearmodelRidge produces a large number of labeling errors for the pixels Important artifacts are observed on the reconstructed image contrary to the L1 penalization Note in particular the circular artifact separating the pixels in the corners that have contributed to fewer projections than the central disk

523 Topic extraction with Nonnegative Matrix Factorization and Latent Dirichlet
Allocation
This is an example of applying sklearndecompositionNMF andsklearndecomposition
LatentDirichletAllocation on a corpus of documents and extract additive models of the topic structure

of the corpus The output is a list of topics each represented as a list of terms weights are not shown
Nonnegative Matrix Factorization is applied with two different objective functions the Frobenius norm and the
generalized KullbackLeibler divergence The latter is equivalent to Probabilistic Latent Semantic Indexing
The default parameters nsamples nfeatures ncomponents should make the example runnable in a couple of
tens of seconds You can try to increase the dimensions of the problem but be aware that the time complexity is
polynomial in NMF In LDA the time complexity is proportional to nsamples iterations

526 Species distribution modeling
Modeling species' geographic distributions is an important problem in conservation biology In this example we model the geographic distribution of two south american mammals given past observations and 14 environmental variables Since we have only positive examples there are no unsuccessful observations we cast this problem as a density estimation problem and use the OneClassSVM provided by the package sklearnsvm as our modeling tool The dataset is provided by Phillips et al 2006 If available the example uses basemap to plot the coast lines and national boundaries of South America
The two species are
• "Bradypus variegatus" the Brownthroated Sloth
• "Microryzomys minutus" also known as the Forest Small Rice Rat a rodent that lives in Peru Colombia Ecuador Peru and Venezuela
References
• "Maximum entropy modeling of species geographic distributions" S J Phillips R P Anderson R E Schapire Ecological Modelling 190231259 2006

527 Visualizing the stock market structure
This example employs several unsupervised learning techniques to extract the stock market structure from variations in historical quotes
The quantity that we use is the daily variation in quote price quotes that are linked tend to cofluctuate during a day
Learning a graph structure
We use sparse inverse covariance estimation to find which quotes are correlated conditionally on the others Specifically sparse inverse covariance gives us a graph that is a list of connection For each symbol the symbols that it is connected too are those useful to explain its fluctuations
Clustering
We use clustering to group together quotes that behave similarly Here amongst the various clustering techniques available in the scikitlearn we use Affinity Propagation as it does not enforce equalsize clusters and it can choose automatically the number of clusters from the data
Note that this gives us a different indication than the graph as the graph reflects conditional relations between variables while the clustering reflects marginal properties variables clustered together can be considered as having a similar impact at the level of the full stock market
Embedding in 2D space
For visualization purposes we need to lay out the different symbols on a 2D canvas For this we use Manifold learning techniques to retrieve 2D embedding
52 Examples based on real world datasets 741

Visualization
The output of the 3 models are combined in a 2D graph where nodes represents the stocks and edges the
• cluster labels are used to define the color of the nodes
• the sparse covariance model is used to display the strength of the edges
• the 2D embedding is used to position the nodes in the plan
This example has a fair amount of visualizationrelated code as visualization is crucial here to display the graph One of the challenge is to position the labels minimizing overlap For this we use an heuristic based on the direction of the nearest neighbor along each axis

528 Wikipedia principal eigenvector
A classical way to assert the relative importance of vertices in a graph is to compute the principal eigenvector of the adjacency matrix so as to assign to each vertex the values of the components of the first eigenvector as a centrality score
httpsenwikipediaorgwikiEigenvectorcentrality
On the graph of webpages and links those values are called the PageRank scores by Google
The goal of this example is to analyze the graph of links inside wikipedia articles to rank articles by relative importance according to this eigenvector centrality
The traditional way to compute the principal eigenvector is to use the power iteration method
httpsenwikipediaorgwikiPoweriteration

scikitlearn user guide Release 0213
Here the computation is achieved thanks to Martinsson's Randomized SVD algorithm implemented in scikitlearn
The graph data is fetched from the DBpedia dumps DBpedia is an extraction of the latent structured data of the Wikipedia content

5210 Prediction Latency
This is an example showing the prediction latency of various scikitlearn estimators
The goal is to measure the latency one can expect when doing predictions either in bulk or atomic ie one by one
mode
The plots represent the distribution of the prediction latency as a boxplot

5211 Outofcore classification of text documents
This is an example showing how scikitlearn can be used for classification using an outofcore approach learning from data that doesn’t fit into main memory We make use of an online classifier ie one that supports the partialfit method that will be fed with batches of examples To guarantee that the features space remains the same over time
52 Examples based on real world datasets 763

we leverage a HashingVectorizer that will project each example into the same feature space This is especially useful
in the case of text classification where new features words may appear in each batch
The dataset used in this example is Reuters21578 as provided by the UCI ML repository It will be automatically
downloaded and uncompressed on first run
The plot represents the learning curve of the classifier the evolution of classification accuracy over the course of the
minibatches Accuracy is measured on the first 1000 samples held out as a validation set
To limit the memory consumption we queue examples up to a fixed amount before feeding them to the learner

533 Biclustering documents with the Spectral Coclustering algorithm
This example demonstrates the Spectral Coclustering algorithm on the twenty newsgroups dataset The ‘composms windowsmisc’ category is excluded because it contains many posts containing nothing but data
The TFIDF vectorized posts form a word frequency matrix which is then biclustered using Dhillon’s Spectral Co Clustering algorithm The resulting documentword biclusters indicate subsets words used more often in those subsets documents
For a few of the best biclusters its most common document categories and its ten most important words get printed The best biclusters are determined by their normalized cut The best words are determined by comparing their sums inside and outside the bicluster
For comparison the documents are also clustered using MiniBatchKMeans The document clusters derived from the biclusters achieve a better Vmeasure than clusters found by MiniBatchKMeans

54 Calibration
Examples illustrating the calibration of predicted probabilities of classifiers
Note Click here to download the full example code
54 Calibration 787

541 Comparison of Calibration of Classifiers
Well calibrated classifiers are probabilistic classifiers for which the output of the predictproba method can be directly interpreted as a confidence level For instance a well calibrated binary classifier should classify the samples such that among the samples to which it gave a predictproba value close to 08 approx 80 actually belong to the positive class
LogisticRegression returns well calibrated predictions as it directly optimizes logloss In contrast the other methods return biased probabilities with different biases per method
• GaussianNaiveBayes tends to push probabilities to 0 or 1 note the counts in the histograms This is mainly because it makes the assumption that features are conditionally independent given the class which is not the case in this dataset which contains 2 redundant features
• RandomForestClassifier shows the opposite behavior the histograms show peaks at approx 02 and 09 probability while probabilities close to 0 or 1 are very rare An explanation for this is given by NiculescuMizil and Caruana1 “Methods such as bagging and random forests that average predictions from a base set of models can have difficulty making predictions near 0 and 1 because variance in the underlying base models will bias predictions that should be near zero or one away from these values Because predictions are restricted to the interval 01 errors caused by variance tend to be one sided near zero and one For example if a model should predict p 0 for a case the only way bagging can achieve this is if all bagged trees predict zero If we add noise to the trees that bagging is averaging over this noise will cause some trees to predict values larger than 0 for this case thus moving the average prediction of the bagged ensemble away from 0 We observe this effect most strongly with random forests because the baselevel trees trained with random forests have relatively high variance due to feature subsetting” As a result the calibration curve shows a characteristic sigmoid shape indicating that the classifier could trust its “intuition” more and return probabilities closer to 0 or 1 typically
• Support Vector Classification SVC shows an even more sigmoid curve as the RandomForestClassifier which is typical for maximummargin methods compare NiculescuMizil and Caruana1 which focus on hard samples that are close to the decision boundary the support vectors

542 Probability Calibration curves
When performing classification one often wants to predict not only the class label but also the associated probability This probability gives some kind of confidence on the prediction This example demonstrates how to display how well calibrated the predicted probabilities are and how to calibrate an uncalibrated classifier
The experiment is performed on an artificial dataset for binary classification with 100000 samples 1000 of them are used for model fitting with 20 features Of the 20 features only 2 are informative and 10 are redundant The first figure shows the estimated probabilities obtained with logistic regression Gaussian naive Bayes and Gaussian naive Bayes with both isotonic calibration and sigmoid calibration The calibration performance is evaluated with Brier score reported in the legend the smaller the better One can observe here that logistic regression is well calibrated while raw Gaussian naive Bayes performs very badly This is because of the redundant features which violate the assumption of featureindependence and result in an overly confident classifier which is indicated by the typical transposedsigmoid curve
Calibration of the probabilities of Gaussian naive Bayes with isotonic regression can fix this issue as can be seen from the nearly diagonal calibration curve Sigmoid calibration also improves the brier score slightly albeit not as strongly as the nonparametric isotonic regression This can be attributed to the fact that we have plenty of calibration data such that the greater flexibility of the nonparametric model can be exploited
The second figure shows the calibration curve of a linear supportvector classifier LinearSVC LinearSVC shows the opposite behavior as Gaussian naive Bayes the calibration curve has a sigmoid curve which is typical for an underconfident classifier In the case of LinearSVC this is caused by the margin property of the hinge loss which lets the model focus on hard samples that are close to the decision boundary the support vectors
Both kinds of calibration can fix this issue and yield nearly identical results This shows that sigmoid calibration can deal with situations where the calibration curve of the base classifier is sigmoid eg for LinearSVC but not where it is transposedsigmoid eg Gaussian naive Bayes

543 Probability calibration of classifiers
When performing classification you often want to predict not only the class label but also the associated probability This probability gives you some kind of confidence on the prediction However not all classifiers provide well calibrated probabilities some being overconfident while others being underconfident Thus a separate calibration of predicted probabilities is often desirable as a postprocessing This example illustrates two different methods for this calibration and evaluates the quality of the returned probabilities using Brier's score see httpsenwikipediaorg wikiBrierscore
Compared are the estimated probability using a Gaussian naive Bayes classifier without calibration with a sigmoid calibration and with a nonparametric isotonic calibration One can observe that only the nonparametric model is able to provide a probability calibration that returns probabilities close to the expected 05 for most of the samples belonging to the middle cluster with heterogeneous labels This results in a significantly improved Brier score

544 Probability Calibration for 3class classification
This example illustrates how sigmoid calibration changes predicted probabilities for a 3class classification problem Illustrated is the standard 2simplex where the three corners correspond to the three classes Arrows point from the probability vectors predicted by an uncalibrated classifier to the probability vectors predicted by the same classifier after sigmoid calibration on a holdout validation set Colors indicate the true class of an instance red class 1 green class 2 blue class 3
The base classifier is a random forest classifier with 25 base estimators trees If this classifier is trained on all 800 training datapoints it is overly confident in its predictions and thus incurs a large logloss Calibrating an identical classifier which was trained on 600 datapoints with method’sigmoid’ on the remaining 200 datapoints reduces the confidence of the predictions ie moves the probability vectors from the edges of the simplex towards the center This calibration results in a lower logloss Note that an alternative would have been to increase the number of base estimators which would have resulted in a similar decrease in logloss

553 Plot classification probability
Plot the classification probability for different classifiers We use a 3 class dataset and we classify it with a Sup port Vector classifier L1 and L2 penalized logistic regression with either a OneVsRest or multinomial setting and Gaussian process classification
Linear SVC is not a probabilistic classifier by default but it has a builtin calibration option enabled in this example probabilityTrue
The logistic regression with OneVsRest is not a multiclass classifier out of the box As a result it has more trouble in separating class 2 and 3 than the other estimators

554 Classifier comparison
A comparison of a several classifiers in scikitlearn on synthetic datasets The point of this example is to illustrate the nature of decision boundaries of different classifiers This should be taken with a grain of salt as the intuition conveyed by these examples does not necessarily carry over to real datasets
Particularly in highdimensional spaces data can more easily be separated linearly and the simplicity of classifiers such as naive Bayes and linear SVMs might lead to better generalization than is achieved by other classifiers
The plots show training points in solid colors and testing points semitransparent The lower right shows the classifi cation accuracy on the test set

563 Demonstration of kmeans assumptions

This example is meant to illustrate situations where kmeans will produce unintuitive and possibly unexpected clusters In the first three plots the input data does not conform to some implicit assumption that kmeans makes and undesirable clusters are produced as a result In the last plot kmeans returns intuitive clusters despite unevenly sized blobs

564 Online learning of a dictionary of parts of faces
This example uses a large dataset of faces to learn a set of 20 x 20 images patches that constitute faces
From the programming standpoint it is interesting because it shows how to use the online API of the scikitlearn
to process a very large dataset by chunks The way we proceed is that we load an image at a time and extract
randomly 50 patches from this image Once we have accumulated 500 of these patches using 10 images we run the
partialfit method of the online KMeans object MiniBatchKMeans
The verbose setting on the MiniBatchKMeans enables us to see that some clusters are reassigned during the successive
calls to partialfit This is because the number of patches that they represent has become too low and it is better to
choose a random new cluster

566 Agglomerative clustering with and without structure
This example shows the effect of imposing a connectivity graph to capture local structure in the data The graph is simply the graph of 20 nearest neighbors
Two consequences of imposing a connectivity can be seen First clustering with a connectivity matrix is much faster Second when using a connectivity matrix single average and complete linkage are unstable and tend to create a few clusters that grow very quickly Indeed average and complete linkage fight this percolation behavior by considering all the distances between two clusters when merging them while single linkage exaggerates the behaviour by considering

only the shortest distance between clusters The connectivity graph breaks this mechanism for average and complete linkage making them resemble the more brittle single linkage This effect is more pronounced for very sparse graphs try decreasing the number of neighbors in kneighborsgraph and with complete linkage In particular having a very small number of neighbors in the graph imposes a geometry that is close to that of single linkage which is well known to have this percolation instability

568 Segmenting the picture of greek coins in regions

This example uses Spectral clustering on a graph created from voxeltovoxel difference on an image to break this image into multiple partlyhomogeneous regions

This procedure spectral clustering on an image is an efficient approximate solution for finding normalized graph cuts

There are two options to assign labels

• with ‘kmeans’ spectral clustering will cluster samples in the embedding space using a kmeans algorithm
• whereas ‘discrete’ will iteratively search for the closest partition space to the embedding space

569 Kmeans Clustering

The plots display firstly what a Kmeans algorithm would yield using three clusters It is then shown what the effect of a bad initialization is on the classification process By setting ninit to only 1 default is 10 the amount of times that the algorithm will be run with different centroid seeds is reduced The next plot displays what using eight clusters would deliver and finally the ground truth

5610 Various Agglomerative Clustering on a 2D embedding of digits
An illustration of various linkage option for agglomerative clustering on a 2D embedding of the digits dataset
The goal of this example is to show intuitively how the metrics behave and not to find good clusters for the digits
This is why the example works on a 2D embedding
What this example shows us is the behavior “rich getting richer” of agglomerative clustering that tends to create uneven
cluster sizes This behavior is pronounced for the average linkage strategy that ends up with a couple of singleton
clusters while in the case of single linkage we get a single central cluster with all other clusters being drawn from
noise points around the fringes

5611 Spectral clustering for image segmentation
In this example an image with connected circles is generated and spectral clustering is used to separate the circles
In these settings the Spectral clustering approach solves the problem know as ‘normalized graph cuts’ the image is seen as a graph of connected voxels and the spectral clustering algorithm amounts to choosing graph cuts defining regions while minimizing the ratio of the gradient along the cut and the volume of the region
As the algorithm tries to balance the volume ie balance the region sizes if we take circles with different sizes the segmentation fails
In addition as there is no useful information in the intensity of the image or its gradient we choose to perform the spectral clustering on a graph that is only weakly informed by the gradient This is close to performing a V oronoi partition of the graph
In addition we use the mask of the objects to restrict the graph to the outline of the objects In this example we are interested in separating the objects one from the other and not from the background

5614 Color Quantization using KMeans

Performs a pixelwise Vector Quantization VQ of an image of the summer palace China reducing the number of colors required to show the image from 96615 unique colors to 64 while preserving the overall appearance quality In this example pixels are represented in a 3Dspace and Kmeans is used to find 64 color clusters In the image processing literature the codebook obtained from Kmeans the cluster centers is called the color palette Using a single byte up to 256 colors can be addressed whereas an RGB encoding requires 3 bytes per pixel The GIF file format for example uses such a palette

For comparison a quantized image using a random codebook colors picked up randomly is also shown

5615 Hierarchical clustering structured vs unstructured ward
Example builds a swiss roll dataset and runs hierarchical clustering on their position
For more information see Hierarchical clustering
In a first step the hierarchical clustering is performed without connectivity constraints on the structure and is solely based on distance whereas in a second step the clustering is restricted to the kNearest Neighbors graph it’s a hierarchical clustering with structure prior
Some of the clusters learned without connectivity constraints do not respect the structure of the swiss roll and extend across different folds of the manifolds On the opposite when opposing connectivity constraints the clusters form a nice parcellation of the swiss roll

5616 Agglomerative clustering with different metrics
Demonstrates the effect of different metrics on the hierarchical clustering
The example is engineered to show the effect of the choice of different metrics It is applied to waveforms which can be seen as highdimensional vector Indeed the difference between metrics is usually more pronounced in high dimension in particular for euclidean and cityblock
We generate data from three groups of waveforms Two of the waveforms waveform 1 and waveform 2 are proportional one to the other The cosine distance is invariant to a scaling of the data as a result it cannot distinguish these two waveforms Thus even with no noise clustering using this distance will not separate out waveform 1 and 2
We add observation noise to these waveforms We generate very sparse noise only 6 of the time points contain noise As a result the l1 norm of this noise ie “cityblock” distance is much smaller than it’s l2 norm “euclidean” distance This can be seen on the interclass distance matrices the values on the diagonal that characterize the spread of the class are much bigger for the Euclidean distance than for the cityblock distance
When we apply clustering to the data we find that the clustering reflects what was in the distance matrices Indeed for the Euclidean distance the classes are illseparated because of the noise and thus the clustering does not separate the waveforms For the cityblock distance the separation is good and the waveform classes are recovered Finally the cosine distance does not separate at all waveform 1 and 2 thus the clustering puts them in the same cluster

5617 Inductive Clustering
Clustering can be expensive especially when our dataset contains millions of datapoints Many clustering algorithms are not inductive and so cannot be directly applied to new data samples without recomputing the clustering which may be intractable Instead we can use clustering to then learn an inductive model with a classifier which has several benefits
• it allows the clusters to scale and apply to new data
• unlike refitting the clusters to new samples it makes sure the labelling procedure is consistent over time
• it allows us to use the inferential capabilities of the classifier to describe or explain the clusters
This example illustrates a generic implementation of a metaestimator which extends clustering by inducing a classifier from the cluster labels

5618 Demo of OPTICS clustering algorithm
Finds core samples of high density and expands clusters from them This example uses data that is generated so that the clusters have different densities The sklearnclusterOPTICS is first used with its Xi cluster detec tion method and then setting specific thresholds on the reachability which corresponds to sklearncluster DBSCAN We can see that the different clusters of OPTICS’s Xi method can be recovered with different choices of thresholds in DBSCAN

5619 Compare BIRCH and MiniBatchKMeans
This example compares the timing of Birch with and without the global clustering step and MiniBatchKMeans on a synthetic dataset having 100000 samples and 2 features generated using makeblobs
Ifnclusters is set to None the data is reduced from 100000 samples to a set of 158 clusters This can be viewed as a preprocessing step before the final global clustering step that further reduces these 158 clusters to 100 clusters
Out
Birch without global clustering as the final step took 247 seconds
nclusters 158
Birch with global clustering as the final step took 290 seconds
nclusters 100
Time taken to run MiniBatchKMeans 360 seconds

5620 Empirical evaluation of the impact of kmeans initialization
Evaluate the ability of kmeans initializations strategies to make the algorithm convergence robust as measured by the relative standard deviation of the inertia of the clustering ie the sum of squared distances to the nearest cluster center
The first plot shows the best inertia reached for each combination of the model KMeans orMiniBatchKMeans and the init method initrandom orinitkmeans for increasing values of the ninit parameter that controls the number of initializations
The second plot demonstrate one single run of the MiniBatchKMeans estimator using a initrandom and ninit1 This run leads to a bad convergence local optimum with estimated centers stuck between ground truth clusters
The dataset used for evaluation is a 2D grid of isotropic Gaussian clusters widely spaced

5621 Adjustment for chance in clustering performance evaluation
The following plots demonstrate the impact of the number of clusters and number of samples on various clustering performance evaluation metrics
Nonadjusted measures such as the VMeasure show a dependency between the number of clusters and the number of samples the mean VMeasure of random labeling increases significantly as the number of clusters is closer to the total number of samples used to compute the measure
Adjusted for chance measure such as ARI display some random variations centered around a mean score of 00 for any number of samples and clusters
Only adjusted measures can hence safely be used as a consensus index to evaluate the average stability of clustering algorithms for a given value of k on various overlapping subsamples of the dataset

5623 Comparison of the KMeans and MiniBatchKMeans clustering algorithms
We want to compare the performance of the MiniBatchKMeans and KMeans the MiniBatchKMeans is faster but gives slightly different results see Mini Batch KMeans
We will cluster a set of data first with KMeans and then with MiniBatchKMeans and plot the results We will also plot the points that are labelled differently between the two algorithms

5624 A demo of KMeans clustering on the handwritten digits data
In this example we compare the various initialization strategies for Kmeans in terms of runtime and quality of the results
As the ground truth is known here we also apply different cluster quality metrics to judge the goodness of fit of the cluster labels to the ground truth
Cluster quality metrics evaluated see Clustering performance evaluation for definitions and discussions of the metrics

5625 Comparing different hierarchical linkage methods on toy datasets
This example shows characteristics of different linkage methods for hierarchical clustering on datasets that are “inter esting” but still in 2D
The main observations to make are
• single linkage is fast and can perform well on nonglobular data but it performs poorly in the presence of noise
• average and complete linkage perform well on cleanly separated globular clusters but have mixed results other wise
• Ward is the most effective method for noisy data
While these examples give some intuition about the algorithms this intuition might not apply to very high dimensional data

5626 Selecting the number of clusters with silhouette analysis on KMeans clus
tering
Silhouette analysis can be used to study the separation distance between the resulting clusters The silhouette plot displays a measure of how close each point in one cluster is to points in the neighboring clusters and thus provides a way to assess parameters like number of clusters visually This measure has a range of 1 1
Silhouette coefficients as these values are referred to as near 1 indicate that the sample is far away from the neigh boring clusters A value of 0 indicates that the sample is on or very close to the decision boundary between two neighboring clusters and negative values indicate that those samples might have been assigned to the wrong cluster
In this example the silhouette analysis is used to choose an optimal value for nclusters The silhouette plot shows that thenclusters value of 3 5 and 6 are a bad pick for the given data due to the presence of clusters with below average silhouette scores and also due to wide fluctuations in the size of the silhouette plots Silhouette analysis is more ambivalent in deciding between 2 and 4
Also from the thickness of the silhouette plot the cluster size can be visualized The silhouette plot for cluster 0 when nclusters is equal to 2 is bigger in size owing to the grouping of the 3 sub clusters into one big cluster However when thenclusters is equal to 4 all the plots are more or less of similar thickness and hence are of similar sizes as can be also verified from the labelled scatter plot on the right

5627 Comparing different clustering algorithms on toy datasets
This example shows characteristics of different clustering algorithms on datasets that are “interesting” but still in 2D
With the exception of the last dataset the parameters of each of these datasetalgorithm pairs has been tuned to produce
good clustering results Some algorithms are more sensitive to parameter values than others
The last dataset is an example of a ‘null’ situation for clustering the data is homogeneous and there is no good
clustering For this example the null dataset uses the same parameters as the dataset in the row above it which
represents a mismatch in the parameter values and the data structure
While these examples give some intuition about the algorithms this intuition might not apply to very high dimensional
data

908 Chapter 5 Examples

571 Concatenating multiple feature extraction methods
In many realworld examples there are many ways to extract features from a dataset Often it is beneficial to combine several methods to obtain good performance This example shows how to use FeatureUnion to combine features obtained by PCA and univariate selection
Combining features using this transformer has the benefit that it allows cross validation and grid searches over the whole process
The combination used in this example is not particularly helpful on this dataset and is only used to illustrate the usage of FeatureUnion

573 Column Transformer with Mixed Types
This example illustrates how to apply different preprocessing and feature extraction pipelines to different subsets of features using sklearncomposeColumnTransformer This is particularly handy for the case of datasets that contain heterogeneous data types since we may want to scale the numeric features and onehot encode the categorical ones
In this example the numeric data is standardscaled after meanimputation while the categorical data is onehot encoded after imputing missing values with a new category missing
Finally the preprocessing pipeline is integrated in a full prediction pipeline using sklearnpipeline Pipeline together with a simple classification model
 Author Pedro Morales partmoralesgmailcom

 License BSD 3 clause
```
import pandas as pd
import numpy as np
from sklearncompose import ColumnTransformer
from sklearnpipeline import Pipeline

574 Selecting dimensionality reduction with Pipeline and GridSearchCV
This example constructs a pipeline that does dimensionality reduction followed by prediction with a support vector
classifier It demonstrates the use of GridSearchCV andPipeline to optimize over different classes of estimators

scikitlearn user guide Release 0213
in a single CV run – unsupervised PCA andNMF dimensionality reductions are compared to univariate feature selection during the grid search
Additionally Pipeline can be instantiated with the memory argument to memoize the transformers within the pipeline avoiding to fit again the same transformers over and over
Note that the use of memory to enable caching becomes interesting when the fitting of a transformer is costly
Illustration of Pipeline andGridSearchCV
This section illustrates the use of a Pipeline withGridSearchCV
Authors Robert McGibbon Joel Nothman Guillaume Lemaitre

Caching transformers within a Pipeline
It is sometimes worthwhile storing the state of a specific transformer since it could be used again Using a pipeline inGridSearchCV triggers such situations Therefore we use the argument memory to enable caching

scikitlearn user guide Release 0213
Warning Note that this example is however only an illustration since for this specific case fitting
PCA is not necessarily slower than loading the cache Hence use the memory constructor parameter
when the fitting of a transformer is costly

ThePCA fitting is only computed at the evaluation of the first configuration of the Cparameter of the LinearSVC
classifier The other configurations of Cwill trigger the loading of the cached PCA estimator data leading to save pro
cessing time Therefore the use of caching the pipeline using memory is highly beneficial when fitting a transformer
is costly

575 Column Transformer with Heterogeneous Data Sources
Datasets can often contain components of that require different feature extraction and processing pipelines This
scenario might occur when
1 Your dataset consists of heterogeneous data types eg raster images and text captions
2 Your dataset is stored in a Pandas DataFrame and different columns require different processing pipelines
This example demonstrates how to use sklearncomposeColumnTransformer on a dataset containing dif
ferent types of features We use the 20newsgroups dataset and compute standard bagofwords features for the subject
line and body in separate pipelines as well as ad hoc features on the body We combine them with weights using a
ColumnTransformer and finally train a classifier on the combined set of features
The choice of features is not particularly helpful but serves to illustrate the technique

576 Effect of transforming the targets in regression model
In this example we give an overview of the sklearncomposeTransformedTargetRegressor Two
examples illustrate the benefit of transforming the targets before learning a linear regression model The first example
uses synthetic data while the second example is based on the Boston housing data set
 Author Guillaume Lemaitre guillaumelemaitreinriafr

```
A synthetic random regression problem is generated The targets yare modified by i translating all targets such
that all entries are nonnegative and ii applying an exponential function to obtain nonlinear targets which cannot be
fitted using a simple linear model
Therefore a logarithmic nplog1p and an exponential function npexpm1 will be used to transform the targets
before training a linear regression model and using it for prediction
```

58 Covariance estimation
Examples concerning the sklearncovariance module
Note Click here to download the full example code
942 Chapter 5 Examples

581 LedoitWolf vs OAS estimation
The usual covariance maximum likelihood estimate can be regularized using shrinkage Ledoit and Wolf proposed a close formula to compute the asymptotically optimal shrinkage parameter minimizing a MSE criterion yielding the LedoitWolf covariance estimate
Chen et al proposed an improvement of the LedoitWolf shrinkage parameter the OAS coefficient whose convergence is significantly better under the assumption that the data are Gaussian
This example inspired from Chen's publication 1 shows a comparison of the estimated MSE of the LW and OAS methods using Gaussian distributed data

582 Sparse inverse covariance estimation
Using the GraphicalLasso estimator to learn a covariance and sparse precision from a small number of samples
To estimate a probabilistic model eg a Gaussian model estimating the precision matrix that is the inverse covari ance matrix is as important as estimating the covariance matrix Indeed a Gaussian model is parametrized by the precision matrix
To be in favorable recovery conditions we sample the data from a model with a sparse inverse covariance matrix In addition we ensure that the data is not too much correlated limiting the largest coefficient of the precision matrix and that there a no small coefficients in the precision matrix that cannot be recovered In addition with a small number of observations it is easier to recover a correlation matrix rather than a covariance thus we scale the time series
Here the number of samples is slightly larger than the number of dimensions thus the empirical covariance is still invertible However as the observations are strongly correlated the empirical covariance matrix is illconditioned and as a result its inverse –the empirical precision matrix– is very far from the ground truth
If we use l2 shrinkage as with the LedoitWolf estimator as the number of samples is small we need to shrink a lot As a result the LedoitWolf precision is fairly close to the ground truth precision that is not far from being diagonal but the offdiagonal structure is lost
The l1penalized estimator can recover part of this offdiagonal structure It learns a sparse precision It is not able to recover the exact sparsity pattern it detects too many nonzero coefficients However the highest nonzero coefficients of the l1 estimated correspond to the nonzero coefficients in the ground truth Finally the coefficients of the l1 precision estimate are biased toward zero because of the penalty they are all smaller than the corresponding ground truth value as can be seen on the figure
Note that the color range of the precision matrices is tweaked to improve readability of the figure The full range of values of the empirical precision is not displayed
The alpha parameter of the GraphicalLasso setting the sparsity of the model is set by internal crossvalidation in the GraphicalLassoCV As can be seen on figure 2 the grid to compute the crossvalidation score is iteratively refined in the neighborhood of the maximum

583 Shrinkage covariance estimation LedoitWolf vs OAS and maxlikelihood
When working with covariance estimation the usual approach is to use a maximum likelihood estimator such as thesklearncovarianceEmpiricalCovariance It is unbiased ie it converges to the true population covariance when given many observations However it can also be beneficial to regularize it in order to reduce its variance this in turn introduces some bias This example illustrates the simple regularization used in Shrunk Covariance estimators In particular it focuses on how to set the amount of regularization ie how to choose the biasvariance tradeoff
Here we compare 3 approaches
• Setting the parameter by crossvalidating the likelihood on three folds according to a grid of potential shrinkage parameters
• A close formula proposed by Ledoit and Wolf to compute the asymptotically optimal regularization parameter minimizing a MSE criterion yielding the sklearncovarianceLedoitWolf covariance estimate
• An improvement of the LedoitWolf shrinkage the sklearncovarianceOAS proposed by Chen et al
Its convergence is significantly better under the assumption that the data are Gaussian in particular for small samples
To quantify estimation error we plot the likelihood of unseen data for different values of the shrinkage parameter We also show the choices by crossvalidation or with the LedoitWolf and OAS estimates
Note that the maximum likelihood estimate corresponds to no shrinkage and thus performs poorly The LedoitWolf estimate performs really well as it is close to the optimal and is computational not costly In this example the OAS estimate is a bit further away Interestingly both approaches outperform crossvalidation which is significantly most computationally costly

584 Robust covariance estimation and Mahalanobis distances relevance
An example to show covariance estimation with the Mahalanobis distances on Gaussian distributed data
For Gaussian distributed data the distance of an observation □□to the mode of the distribution can be computed using its Mahalanobis distance □□Σ□□2 □□−□′□−1□□−□where □and□are the location and the covariance of the underlying Gaussian distribution
In practice □and□are replaced by some estimates The usual covariance maximum likelihood estimate is very sensitive to the presence of outliers in the data set and therefor the corresponding Mahalanobis distances are One would better have to use a robust estimator of covariance to guarantee that the estimation is resistant to “erroneous” observations in the data set and that the associated Mahalanobis distances accurately reflect the true organisation of the observations
The Minimum Covariance Determinant estimator is a robust highbreakdown point ie it can be used to estimate the covariance matrix of highly contaminated datasets up to□samples−□features−1
2outliers estimator of covariance The idea is
to find□samples□features1
2observations whose empirical covariance has the smallest determinant yielding a “pure” subset of observations from which to compute standards estimates of location and covariance
The Minimum Covariance Determinant estimator MCD has been introduced by PJRousseuw in 1
This example illustrates how the Mahalanobis distances are affected by outlying data observations drawn from a contaminating distribution are not distinguishable from the observations coming from the real Gaussian distribution that one may want to work with Using MCDbased Mahalanobis distances the two populations become distinguish able Associated applications are outliers detection observations ranking clustering For visualization purpose the cubic root of the Mahalanobis distances are represented in the boxplot as Wilson and Hilferty suggest 2

585 Robust vs Empirical covariance estimate
The usual covariance maximum likelihood estimate is very sensitive to the presence of outliers in the data set In such a case it would be better to use a robust estimator of covariance to guarantee that the estimation is resistant to "erroneous" observations in the data set12
Minimum Covariance Determinant Estimator
The Minimum Covariance Determinant estimator is a robust highbreakdown point ie it can be used to estimate the covariance matrix of highly contaminated datasets up to□samples−□features−1
2outliers estimator of covariance The idea is
to find□samples□features1
2observations whose empirical covariance has the smallest determinant yielding a "pure" subset
of observations from which to compute standards estimates of location and covariance After a correction step aiming at compensating the fact that the estimates were learned from only a portion of the initial data we end up with robust estimates of the data set location and covariance
The Minimum Covariance Determinant estimator MCD has been introduced by PJRousseuw in3
Evaluation
In this example we compare the estimation errors that are made when using various types of location and covariance estimates on contaminated Gaussian distributed data sets
• The mean and the empirical covariance of the full dataset which break down as soon as there are outliers in the data set
• The robust MCD that has a low error provided □samples 5□features
• The mean and the empirical covariance of the observations that are known to be good ones This can be considered as a "perfect" MCD estimation so one can trust our implementation by comparing to this case

5113 Incremental PCA
Incremental principal component analysis IPCA is typically used as a replacement for principal component analysis PCA when the dataset to be decomposed is too large to fit in memory IPCA builds a lowrank approximation for the input data using an amount of memory which is independent of the number of input data samples It is still dependent on the input data features but changing the batch size allows for control of memory usage
This example serves as a visual check that IPCA is able to find a similar projection of the data to PCA to a sign flip while only processing a few samples at a time This can be considered a “toy example” as IPCA is intended for large datasets which do not fit in main memory requiring incremental approaches

5114 Comparison of LDA and PCA 2D projection of Iris dataset
The Iris dataset represents 3 kind of Iris flowers Setosa Versicolour and Virginica with 4 attributes sepal length sepal width petal length and petal width
Principal Component Analysis PCA applied to this data identifies the combination of attributes principal compo nents or directions in the feature space that account for the most variance in the data Here we plot the different samples on the 2 first principal components
Linear Discriminant Analysis LDA tries to identify attributes that account for the most variance between classes In particular LDA in contrast to PCA is a supervised method using known class labels

5115 Blind source separation using FastICA
An example of estimating sources from noisy data
Independent component analysis ICA is used to estimate sources given noisy measurements Imagine 3 instruments playing simultaneously and 3 microphones recording the mixed signals ICA is used to recover the sources ie what is played by each instrument Importantly PCA fails at recovering our instruments since the related signals reflect nonGaussian processes

5117 FastICA on 2D point clouds
This example illustrates visually in the feature space a comparison by results using two different component analysis techniques
Independent component analysis ICA vsPrincipal component analysis PCA
Representing ICA in the feature space gives the view of ‘geometric ICA’ ICA is an algorithm that finds directions in the feature space corresponding to projections with high nonGaussianity These directions need not be orthogonal in the original feature space but they are orthogonal in the whitened feature space in which all directions correspond to the same variance
PCA on the other hand finds orthogonal directions in the raw feature space that correspond to directions accounting for maximum variance
Here we simulate independent sources using a highly nonGaussian process 2 student T with a low number of degrees of freedom top left figure We mix them to create observations top right figure In this raw observation space directions identified by PCA are represented by orange vectors We represent the signal in the PCA space after whitening by the variance corresponding to the PCA vectors lower left Running ICA corresponds to finding a rotation in this space to identify the directions of largest nonGaussianity lower right

scikitlearn user guide Release 0213
5119 Model selection with Probabilistic PCA and Factor Analysis FA
Probabilistic PCA and Factor Analysis are probabilistic models The consequence is that the likelihood of new data can be used for model selection and covariance estimation Here we compare PCA and FA with crossvalidation on low rank data corrupted with homoscedastic noise noise variance is the same for each feature or heteroscedastic noise noise variance is the different for each feature In a second step we compare the model likelihood to the likelihoods obtained from shrinkage covariance estimators
One can observe that with homoscedastic noise both FA and PCA succeed in recovering the size of the low rank subspace The likelihood with PCA is higher than FA in this case However PCA fails and overestimates the rank when heteroscedastic noise is present Under appropriate circumstances the low rank models are more likely than shrinkage models
The automatic estimation from Automatic Choice of Dimensionality for PCA NIPS 2000 598604 by Thomas P Minka is also compared

51110 Sparse coding with a precomputed dictionary
Transform a signal as a sparse combination of Ricker wavelets This example visually compares different sparse coding methods using the sklearndecompositionSparseCoder estimator The Ricker also known as Mexican hat or the second derivative of a Gaussian is not a particularly good kernel to represent piecewise constant signals like this one It can therefore be seen how much adding different widths of atoms matters and it therefore motivates learning the dictionary to best fit your type of signals
The richer dictionary on the right is not larger in size heavier subsampling is performed in order to stay on the same order of magnitude

51111 Image denoising using dictionary learning
An example comparing the effect of reconstructing noisy fragments of a raccoon face image using firstly online Dictionary Learning and various transform methods
The dictionary is fitted on the distorted left half of the image and subsequently used to reconstruct the right half Note that even better performance could be achieved by fitting to an undistorted ie noiseless image but here we start from the assumption that it is not available
A common practice for evaluating the results of image denoising is by looking at the difference between the reconstruction and the original image If the reconstruction is perfect this will look like Gaussian noise
It can be seen from the plots that the results of Orthogonal Matching Pursuit OMP with two nonzero coefficients is a bit less biased than when keeping only one the edges look less prominent It is in addition closer from the ground truth in Frobenius norm
The result of Least Angle Regression is much more strongly biased the difference is reminiscent of the local intensity value of the original image
Thresholding is clearly not useful for denoising but it is here to show that it can produce a suggestive output with very high speed and thus be useful for other tasks such as object classification where performance is not necessarily related to visualisation

5125 IsolationForest example
An example using sklearnensembleIsolationForest for anomaly detection
The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature
Since recursive partitioning can be represented by a tree structure the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node
This path length averaged over a forest of such random trees is a measure of normality and our decision function
Random partitioning produces noticeable shorter paths for anomalies Hence when a forest of random trees collec tively produce shorter path lengths for particular samples they are highly likely to be anomalies

5127 Comparing random forests and the multioutput meta estimator
An example to compare multioutput regression with random forest and the multioutputMultiOutputRegressor meta estimator
This example illustrates the use of the multioutputMultiOutputRegressor metaestimator to perform multioutput re gression A random forest regressor is used which supports multioutput regression natively so the results can be compared
The random forest regressor will only ever predict values within the range of observations or closer to zero for each of the targets As a result the predictions are biased towards the centre of the circle
Using a single underlying feature the model learns both the x and y coordinate as output

5129 Gradient Boosting regularization
Illustration of the effect of different regularization strategies for Gradient Boosting The example is taken from Hastie
et al 20091
1T Hastie R Tibshirani and J Friedman “Elements of Statistical Learning Ed 2” Springer 2009

The loss function used is binomial deviance Regularization via shrinkage learningrate 10 improves performance considerably In combination with shrinkage stochastic gradient boosting subsample 10 can produce more accurate models by reducing the variance via bagging Subsampling without shrinkage usually does poorly Another strategy to reduce the variance is by subsampling the features analogous to the random splits in Random Forests via the maxfeatures parameter

51212 Twoclass AdaBoost
This example fits an AdaBoosted decision stump on a nonlinearly separable classification dataset composed of two “Gaussian quantiles” clusters see sklearndatasetsmakegaussianquantiles and plots the decision boundary and decision scores The distributions of decision scores are shown separately for samples of class A and B The predicted class label for each sample is determined by the sign of the decision score Samples with decision scores greater than zero are classified as B and are otherwise classified as A The magnitude of a decision score determines the degree of likeness with the predicted class label Additionally a new dataset could be constructed containing a desired purity of class B for example by only selecting samples with a decision score above some value

51213 OOB Errors for Random Forests
TheRandomForestClassifier is trained using bootstrap aggregation where each new tree is fit from a boot
strap sample of the training observations □□ □□ □□ The outofbag OOB error is the average error for each □□
calculated using predictions from the trees that do not contain □□in their respective bootstrap sample This allows the
RandomForestClassifier to be fit and validated whilst being trained1
The example below demonstrates how the OOB error can be measured at the addition of each new tree during train
ing The resulting plot allows a practitioner to approximate a suitable value of nestimators at which the error
stabilizes

```
import matplotlibpyplot as plt

51214 Hashing feature transformation using Totally Random Trees
RandomTreesEmbedding provides a way to map data to a very highdimensional sparse representation which might be beneficial for classification The mapping is completely unsupervised and very efficient
This example visualizes the partitions given by several trees and shows how the transformation can also be used for nonlinear dimensionality reduction or nonlinear classification
Points that are neighboring often share the same leaf of a tree and therefore share large parts of their hashed repre sentation This allows to separate two concentric circles simply based on the principal components of the transformed data with truncated SVD
In highdimensional spaces linear classifiers often achieve excellent accuracy For sparse binary data BernoulliNB is particularly wellsuited The bottom row compares the decision boundary obtained by BernoulliNB in the transformed space with an ExtraTreesClassifier forests learned on the original data

51215 Multiclass AdaBoosted Decision Trees
This example reproduces Figure 1 of Zhu et al1and shows how boosting can improve prediction accuracy on a multi class problem The classification dataset is constructed by taking a tendimensional standard normal distribution and defining three classes separated by nested concentric tendimensional spheres such that roughly equal numbers of samples are in each class quantiles of the □2distribution
The performance of the SAMME and SAMMER1algorithms are compared SAMMER uses the probability estimates to update the additive model while SAMME uses the classifications only As the example illustrates the SAMMER algorithm typically converges faster than SAMME achieving a lower test error with fewer boosting iterations The error of each algorithm on the test set after each boosting iteration is shown on the left the classification error on the test set of each tree is shown in the middle and the boost weight of each tree is shown on the right All trees have a weight of one in the SAMMER algorithm and therefore are not shown

51216 Discrete versus Real AdaBoost
This example is based on Figure 102 from Hastie et al 20091and illustrates the difference in performance between the discrete SAMME2boosting algorithm and real SAMMER boosting algorithm Both algorithms are evaluated on a binary classification task where the target Y is a nonlinear function of 10 input features
Discrete SAMME AdaBoost adapts based on errors in predicted class labels whereas real SAMMER uses the predicted class probabilities

51217 Early stopping of Gradient Boosting
Gradient boosting is an ensembling technique where several weak learners regression trees are combined to yield a powerful single model in an iterative fashion
Early stopping support in Gradient Boosting enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data
The concept of early stopping is simple We specify a validationfraction which denotes the fraction of the whole dataset that will be kept aside from training to assess the validation loss of the model The gradient boosting model is trained using the training set and evaluated using the validation set When each additional stage of regression tree is added the validation set is used to score the model This is continued until the scores of the model in the last niternochange stages do not improve by atleast tol After that the model is considered to have converged and further addition of stages is “stopped early”
The number of stages of the final model is available at the attribute nestimators
This example illustrates how the early stopping can used in the sklearnensemble GradientBoostingClassifier model to achieve almost the same accuracy as compared to a model built without early stopping using many fewer estimators This can significantly reduce training time memory usage and prediction latency

51218 Feature transformations with ensembles of trees
Transform your features into a higher dimensional sparse space Then train a linear model on these features
First fit an ensemble of trees totally random trees a random forest or gradient boosted trees on the training set Then each leaf of each tree in the ensemble is assigned a fixed arbitrary feature index in a new feature space These leaf indices are then encoded in a onehot fashion
Each sample goes through the decisions of each tree of the ensemble and ends up in one leaf per tree The sample is encoded by setting feature values for these leaves to 1 and the other feature values to 0
The resulting transformer has then learned a supervised sparse highdimensional categorical embedding of the data

51219 Gradient Boosting OutofBag estimates
Outofbag OOB estimates can be a useful heuristic to estimate the “optimal” number of boosting iterations OOB estimates are almost identical to crossvalidation estimates but they can be computed onthefly without the need for repeated model fitting OOB estimates are only available for Stochastic Gradient Boosting ie subsample 1 0 the estimates are derived from the improvement in loss based on the examples not included in the bootstrap sample the socalled outofbag examples The OOB estimator is a pessimistic estimator of the true test loss but remains a fairly good approximation for a small number of trees
The figure shows the cumulative sum of the negative OOB improvements as a function of the boosting iteration As you can see it tracks the test loss for the first hundred iterations but then diverges in a pessimistic way The figure also shows the performance of 3fold cross validation which usually gives a better estimate of the test loss but is computationally more demanding

51220 Single estimator versus bagging biasvariance decomposition
This example illustrates and compares the biasvariance decomposition of the expected mean squared error of a single estimator against a bagging ensemble
In regression the expected mean squared error of an estimator can be decomposed in terms of bias variance and noise On average over datasets of the regression problem the bias term measures the average amount by which the predictions of the estimator differ from the predictions of the best possible estimator for the problem ie the Bayes model The variance term measures the variability of the predictions of the estimator when fit over different instances LS of the problem Finally the noise measures the irreducible part of the error which is due the variability in the data
The upper left figure illustrates the predictions in dark red of a single decision tree trained over a random dataset LS the blue dots of a toy 1d regression problem It also illustrates the predictions in light red of other single decision

trees trained over other and different randomly drawn instances LS of the problem Intuitively the variance term here corresponds to the width of the beam of predictions in light red of the individual estimators The larger the variance the more sensitive are the predictions for xto small changes in the training set The bias term corresponds to the difference between the average prediction of the estimator in cyan and the best possible model in dark blue On this problem we can thus observe that the bias is quite low both the cyan and the blue curves are close to each other while the variance is large the red beam is rather wide

The lower left figure plots the pointwise decomposition of the expected mean squared error of a single decision tree It confirms that the bias term in blue is low while the variance is large in green It also illustrates the noise part of the error which as expected appears to be constant and around 001

The right figures correspond to the same plots but using instead a bagging ensemble of decision trees In both figures we can observe that the bias term is larger than in the previous case In the upper right figure the difference between the average prediction in cyan and the best possible model is larger eg notice the offset around x2 In the lower right figure the bias curve is also slightly higher than in the lower left figure In terms of variance however the beam of predictions is narrower which suggests that the variance is lower Indeed as the lower right figure confirms the variance term in green is lower than for single decision trees Overall the bias variance decomposition is therefore no longer the same The tradeoff is better for bagging averaging several decision trees fit on bootstrap copies of the dataset slightly increases the bias term but allows for a larger reduction of the variance which results in a lower overall mean squared error compare the red curves int the lower figures The script output also confirms this intuition The total error of the bagging ensemble is lower than the total error of a single decision tree and this difference indeed mainly stems from a reduced variance

For further details on biasvariance decomposition see section 73 of1

51221 Plot the decision surfaces of ensembles of trees on the iris dataset
Plot the decision surfaces of forests of randomized trees trained on pairs of features of the iris dataset
This plot compares the decision surfaces learned by a decision tree classifier first column by a random forest classi
fier second column by an extra trees classifier third column and by an AdaBoost classifier fourth column
In the first row the classifiers are built using the sepal width and the sepal length features only on the second row
using the petal length and sepal length only and on the third row using the petal width and the petal length only
In descending order of quality when trained outside of this example on all 4 features using 30 estimators and scored
using 10 fold cross validation we see
ExtraTreesClassifier 095 score
RandomForestClassifier 094 score
AdaBoostDecisionTreemaxdepth3 094 score
DecisionTreemaxdepth None 094 score
Increasing maxdepth for AdaBoost lowers the standard deviation of the scores but the average score does not
improve
See the console’s output for further details about each model
In this example you might try to
1 vary the maxdepth for the DecisionTreeClassifier andAdaBoostClassifier
perhaps try maxdepth3 for theDecisionTreeClassifier ormaxdepthNone for
AdaBoostClassifier
2 varynestimators
It is worth noting that RandomForests and ExtraTrees can be fitted in parallel on many cores as each tree is built
independently of the others AdaBoost’s samples are built sequentially and so do not use multiple cores

Out
DecisionTree with features 0 1 has a score of 09266666666666666
RandomForest with 30 estimators with features 0 1 has a score of 09266666666666666
ExtraTrees with 30 estimators with features 0 1 has a score of 09266666666666666
AdaBoost with 30 estimators with features 0 1 has a score of 084

 Bonus how much can you trust the selection of alpha
 To answer this question we use the LassoCV object that sets its alpha
 parameter automatically from the data by internal crossvalidation ie it
 performs crossvalidation on the training data it receives
 We use external crossvalidation to see how much the automatically obtained
 alphas differ across different crossvalidation folds

5142 Comparison of Ftest and mutual information
This example illustrates the differences between univariate Ftest statistics and mutual information
We consider 3 features x1 x2 x3 distributed uniformly over 0 1 the target depends on them as follows
y x1 sin6 pi x2 01 N0 1 that is the third features is completely irrelevant
The code below plots the dependency of y against individual xi and normalized values of univariate Ftests statistics and mutual information
As Ftest captures only linear dependency it rates x1 as the most discriminative feature On the other hand mutual information can capture any kind of dependency between variables and it rates x2 as the most discriminative feature which probably agrees better with our intuitive perception for this example Both methods correctly marks x3 as irrelevant

5147 Univariate Feature Selection
An example showing univariate feature selection
Noisy non informative features are added to the iris data and univariate feature selection is applied For each feature we plot the pvalues for the univariate feature selection and the corresponding weights of an SVM We can see that univariate feature selection selects the informative features and that these have larger SVM weights
In the total set of features only the 4 first ones are significant We can see that they have the highest score with univariate feature selection The SVM assigns a large weight to one of these features but also Selects many of the noninformative features Applying univariate feature selection before the SVM increases the SVM weight attributed

5153 Comparison of kernel ridge and Gaussian process regression
Both kernel ridge regression KRR and Gaussian process regression GPR learn a target function by employing internally the “kernel trick” KRR learns a linear function in the space induced by the respective kernel which corre sponds to a nonlinear function in the original space The linear function in the kernel space is chosen based on the meansquared error loss with ridge regularization GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses the observed training data to define a likelihood function Based on Bayes theorem a Gaussian posterior distribution over target functions is defined whose mean is used for prediction
A major difference is that GPR can choose the kernel’s hyperparameters based on gradientascent on the marginal likelihood function while KRR needs to perform a grid search on a crossvalidated loss function meansquared error loss A further difference is that GPR learns a generative probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions
This example illustrates both methods on an artificial dataset which consists of a sinusoidal target function and strong noise The figure compares the learned model of KRR and GPR based on a ExpSineSquared kernel which is suited for learning periodic functions The kernel’s hyperparameters control the smoothness l and periodicity of the kernel p Moreover the noise level of the data is learned explicitly by GPR by an additional WhiteKernel component in the kernel and by the regularization parameter alpha of KRR
The figure shows that both methods learn reasonable models of the target function GPR correctly identifies the peri odicity of the function to be roughly 2pi 628 while KRR chooses the doubled periodicity 4pi Besides that GPR provides reasonable confidence bounds on the prediction which are not available for KRR A major difference between the two methods is the time required for fitting and predicting while fitting KRR is fast in principle the gridsearch for hyperparameter optimization scales exponentially with the number of hyperparameters “curse of dimensional ity” The gradientbased optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerable faster on this example with 3dimensional hyperparameter space The time for predicting is similar however generating the variance of the predictive distribution of GPR takes considerable longer than just predicting the mean

5156 Probabilistic predictions with Gaussian process classification GPC
This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparam
eters The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the
hyperparameters corresponding to the maximum logmarginallikelihood LML
While the hyperparameters chosen by optimizing LML have a considerable larger LML they perform slightly worse
according to the logloss on test data The figure shows that this is because they exhibit a steep change of the class
probabilities at the class boundaries which is good but have predicted probabilities close to 05 far away from the
class boundaries which is bad This undesirable effect is caused by the Laplace approximation used internally by
GPC
The second figure shows the logmarginallikelihood for different choices of the kernel’s hyperparameters highlighting
the two choices of the hyperparameters used in the first figure by black dots

5157 Gaussian process regression GPR with noiselevel estimation
This example illustrates that GPR with a sumkernel including a WhiteKernel can estimate the noise level of data
An illustration of the logmarginallikelihood LML landscape shows that there exist two local maxima of LML The first corresponds to a model with a high noise level and a large length scale which explains all variations in the data by noise The second one has a smaller noise level and shorter length scale which explains most of the variation by the noisefree functional relationship The second model has a higher likelihood however depending on the initial value for the hyperparameters the gradientbased optimization might also converge to the highnoise solution It is thus important to repeat the optimization several times for different initializations

5158 Gaussian Processes regression basic introductory example
A simple onedimensional regression example computed in two different ways
1 A noisefree case
2 A noisy case with known noiselevel per datapoint
In both cases the kernel’s parameters are estimated using the maximum likelihood principle
The figures illustrate the interpolating property of the Gaussian Process model as well as its probabilistic nature in the form of a pointwise 95 confidence interval
Note that the parameter alpha is applied as a Tikhonov regularization of the assumed covariance between the training points

5159 Gaussian process regression GPR on Mauna Loa CO2 data
This example is based on Section 543 of “Gaussian Processes for Machine Learning” RW2006 It illustrates an example of complex kernel engineering and hyperparameter optimization using gradient ascent on the logmarginal likelihood The data consists of the monthly average atmospheric CO2 concentrations in parts per million by volume ppmv collected at the Mauna Loa Observatory in Hawaii between 1958 and 2001 The objective is to model the CO2 concentration as a function of the time t
The kernel is composed of several terms that are responsible for explaining different properties of the signal
• a long term smooth rising trend is to be explained by an RBF kernel The RBF kernel with a large lengthscale enforces this component to be smooth it is not enforced that the trend is rising which leaves this choice to the GP The specific lengthscale and the amplitude are free hyperparameters
• a seasonal component which is to be explained by the periodic ExpSineSquared kernel with a fixed periodicity of 1 year The lengthscale of this periodic component controlling its smoothness is a free parameter In order to allow decaying away from exact periodicity the product with an RBF kernel is taken The lengthscale of this RBF component controls the decay time and is a further free parameter
• smaller medium term irregularities are to be explained by a RationalQuadratic kernel component whose length scale and alpha parameter which determines the diffuseness of the lengthscales are to be determined Ac cording to RW2006 these irregularities can better be explained by a RationalQuadratic than an RBF kernel component probably because it can accommodate several lengthscales
• a “noise” term consisting of an RBF kernel contribution which shall explain the correlated noise components such as local weather phenomena and a WhiteKernel contribution for the white noise The relative amplitudes and the RBF’s length scale are further free parameters
Maximizing the logmarginallikelihood after subtracting the target’s mean yields the following kernel with an LML of 83214
3442RBFlengthscale418
 3272RBFlengthscale180 ExpSineSquaredlengthscale144
periodicity1
 04462RationalQuadraticalpha177 lengthscale0957
 01972RBFlengthscale0138 WhiteKernelnoiselevel00336
Thus most of the target signal 344ppm is explained by a longterm rising trend lengthscale 418 years The periodic component has an amplitude of 327ppm a decay time of 180 years and a lengthscale of 144 The long decay time indicates that we have a locally very close to periodic seasonal component The correlated noise has an amplitude of 0197ppm with a length scale of 0138 years and a whitenoise contribution of 0197ppm Thus the

overall noise level is very small indicating that the data can be very well explained by the model The figure shows
also that the model makes very confident predictions until around 2015

516 Missing Value Imputation
Examples concerning the sklearnimpute module
Note Click here to download the full example code
5161 Imputing missing values with variants of IterativeImputer
ThesklearnimputeIterativeImputer class is very flexible it can be used with a variety of estimators
to do roundrobin regression treating every variable as an output in turn
In this example we compare some estimators for the purpose of missing feature imputation with sklearnimpute
IterativeImputer
•BayesianRidge regularized linear regression

•DecisionTreeRegressor nonlinear regression
•ExtraTreesRegressor similar to missForest in R
•KNeighborsRegressor comparable to other KNN imputation approaches
Of particular interest is the ability of sklearnimputeIterativeImputer to mimic the behavior of miss
Forest a popular imputation package for R In this example we have chosen to use sklearnensemble
ExtraTreesRegressor instead ofsklearnensembleRandomForestRegressor as in missForest
due to its increased speed
Note thatsklearnneighborsKNeighborsRegressor is different from KNN imputation which learns
from samples with missing values by using a distance metric that accounts for missing values rather than imput
ing them
The goal is to compare different estimators to see which one is best for the sklearnimpute
IterativeImputer when using a sklearnlinearmodelBayesianRidge estimator on the California
housing dataset with a single value randomly removed from each row
For this particular pattern of missing values we see that sklearnensembleExtraTreesRegressor and
sklearnlinearmodelBayesianRidge give the best results
```

5162 Imputing missing values before building an estimator

Missing values can be replaced by the mean the median or the most frequent value using the basic sklearn imputeSimpleImputer The median is a more robust estimator for data with high magnitude variables which could dominate results otherwise known as a ‘long tail’

Another option is the sklearnimputeIterativeImputer This uses roundrobin linear regression treating every variable as an output in turn The version implemented assumes Gaussian output variables If your features are obviously nonNormal consider transforming them to look more Normal so as to potentially improve performance

In addition of using an imputing method we can also keep an indication of the missing information using sklearn imputeMissingIndicator which might carry some information

5171 Partial Dependence Plots
Partial dependence plots show the dependence between the target function2and a set of ‘target’ features marginalizing over the values of all other features the complement features Due to the limits of human perception the size of the target feature set must be small usually one or two thus the target features are usually chosen among the most important features
This example shows how to obtain partial dependence plots from a MLPRegressor and a GradientBoostingRegressor trained on the California housing dataset The example is taken from1
The plots show four 1way and two 1way partial dependence plots ommitted for MLPRegressor due to computa tion time The target variables for the oneway PDP are median income MedInc average occupants per household AvgOccup median house age HouseAge and average rooms per household AveRooms
2For classification you can think of it as the regression score before the link function
1T Hastie R Tibshirani and J Friedman “Elements of Statistical Learning Ed 2” Springer 2009

We can clearly see that the median house price shows a linear relationship with the median income top left and that the house price drops when the average occupants per household increases top middle The top right plot shows that the house age in a district does not have a strong influence on the median house price so does the average rooms per household The tick marks on the xaxis represent the deciles of the feature values in the training data
We also observe that MLPRegressor has much smoother predictions than GradientBoostingRegressor
For the plots to be comparable it is necessary to subtract the average value of the target y The ‘recursion’ method used by default for GradientBoostingRegressor does not account for the initial predictor in our case the average target Setting the target average to 0 avoids this bias
Partial dependence plots with two target features enable us to visualize interactions among them The twoway partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household We can clearly see an interaction between the two features for an average occupancy greater than two the house price is nearly independent of the house age whereas for values less than two there is a strong dependence on age
On a third figure we have plotted the same partial dependence plot this time in 3 dimensions

5182 Plot Ridge coefficients as a function of the regularization
Shows the effect of collinearity in the coefficients of an estimator
Ridge Regression is the estimator used in this example Each color represents a different feature of the coefficient vector and this is displayed as a function of the regularization parameter
This example also shows the usefulness of applying Ridge regression to highly illconditioned matrices For such matrices a slight change in the target variable can cause huge variances in the calculated weights In such cases it is useful to set a certain regularization alpha to reduce this variation noise
When alpha is very large the regularization effect dominates the squared loss function and the coefficients tend to zero At the end of the path as alpha tends toward zero and the solution tends towards the ordinary least squares coefficients exhibit big oscillations In practise it is necessary to tune alpha in such a way that a balance is maintained between both

5185 Ordinary Least Squares and Ridge Regression Variance
Due to the few points in each dimension and the straight line that linear regression uses to follow these points as well as it can noise on the observations will cause great variance as shown in the first plot Every line’s slope can vary quite a bit for each prediction due to the noise induced in the observations
Ridge regression is basically minimizing a penalised version of the leastsquared function The penalising shrinks the value of the regression coefficients Despite the few data points in each dimension the slope of the prediction is much more stable and the variance in the line itself is greatly reduced in comparison to that of the standard linear regression

5186 Plot Ridge coefficients as a function of the L2 regularization
Ridge Regression is the estimator used in this example Each color in the left plot represents one different dimension of the coefficient vector and this is displayed as a function of the regularization parameter The right plot shows how exact the solution is This example illustrates how a well defined solution is found by Ridge regression and how regularization affects the coefficients and their values The plot on the right shows how the difference of the coefficients from the estimator changes as a function of regularization
In this example the dependent variable Y is set as a function of the input features y Xw c The coefficient vector w is randomly sampled from a normal distribution whereas the bias term c is set to a constant
As alpha tends toward zero the coefficients found by Ridge regression stabilize towards the randomly sampled vector w For big alpha strong regularisation the coefficients are smaller eventually converging at 0 leading to a simpler and biased solution These dependencies can be observed on the left plot
The right plot shows the mean squared error between the coefficients found by the model and the chosen vector w Less regularised models retrieve the exact coefficients error is equal to 0 stronger regularised models increase the error
Please note that in this example the data is nonnoisy hence it is possible to extract the exact coefficients

5188 Regularization path of L1 Logistic Regression
Train l1penalized logistic regression models on a binary classification problem derived from the Iris dataset
The models are ordered from strongest regularized to least regularized The 4 coefficients of the models are collected and plotted as a “regularization path” on the lefthand side of the figure strong regularizers all the coefficients are exactly 0 When regularization gets progressively looser coefficients can get nonzero values one after the other
Here we choose the SAGA solver because it can efficiently optimize for the Logistic Regression loss with a non smooth sparsity inducing l1 penalty
Also note that we set a low value for the tolerance to make sure that the model has converged before collecting the coefficients
We also use warmstartTrue which means that the coefficients of the models are reused to initialize the next model fit to speedup the computation of the fullpath

5189 Polynomial interpolation
This example demonstrates how to approximate a function with a polynomial of degree ndegree by using ridge regression Concretely from nsamples 1d points it suffices to build the Vandermonde matrix which is nsamples x ndegree1 and has the following form
1 x1 x1 2 x1 3   1 x2 x2 2 x2 3
Intuitively this matrix can be interpreted as a matrix of pseudo features the points raised to some power The matrix is akin to but different from the matrix induced by a polynomial kernel
This example shows that you can do nonlinear regression with a linear model using a pipeline to add nonlinear features Kernel methods extend this idea and can induce very high even infinite dimensional feature spaces

51813 Linear Regression Example
This example uses the only the first feature of the diabetes dataset in order to illustrate a twodimensional plot of this regression technique The straight line can be seen in the plot showing how linear regression attempts to draw a straight line that will best minimize the residual sum of squares between the observed responses in the dataset and the responses predicted by the linear approximation
The coefficients the residual sum of squares and the variance score are also calculated

51817 HuberRegressor vs Ridge on dataset with strong outliers
Fit Ridge and HuberRegressor on a dataset with outliers
The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset The Huber regressor is less influenced by the outliers since the model uses the linear loss for these As the parameter epsilon is increased for the Huber regressor the decision function approaches that of the ridge

51818 Joint feature selection with multitask Lasso
The multitask lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks This example simulates sequential measurements each task is a time instant and the relevant features vary in amplitude over time while being the same The multitask lasso imposes that features that are selected at one time point are select for all time point This makes feature selection by the Lasso more stable

51821 MNIST classfification using multinomial logistic L1
Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task We use the SAGA algorithm for this purpose this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize nonsmooth objective functions which is the case with the l1penalty Test accuracy reaches 08 while weight vectors remains sparse and therefore more easily interpretable
Note that this accuracy of this l1penalized linear model is significantly below what can be reached by an l2penalized linear model or a nonlinear multilayer perceptron model on this dataset

51824 TheilSen Regression
Computes a TheilSen Regression on a synthetic dataset
SeeTheilSen estimator generalizedmedianbased estimator for more information on the regressor
Compared to the OLS ordinary least squares estimator the TheilSen estimator is robust against outliers It has
a breakdown point of about 293 in case of a simple linear regression which means that it can tolerate arbitrary
corrupted data outliers of up to 293 in the twodimensional case
The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible com
binations of p subsample points If an intercept is fitted p must be greater than or equal to nfeatures 1 The final
slope and intercept is then defined as the spatial median of these slopes and intercepts
In certain cases TheilSen performs better than RANSAC which is also a robust method This is illustrated in the second
example below where outliers with respect to the xaxis perturb RANSAC Tuning the residualthreshold
parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers
is needed Due to the computational complexity of TheilSen it is recommended to use it only for small problems in
terms of number of samples and features For larger problems the maxsubpopulation parameter restricts the
magnitude of all possible combinations of p subsample points to a randomly chosen subset and therefore also limits the
runtime Therefore TheilSen is applicable to larger problems with the drawback of losing some of its mathematical
properties since it then works on a random subset

51826 Robust linear estimator fitting
Here a sine function is fit with a polynomial of order 3 for values close to zero
Robust fitting is demoed in different situations
1178 Chapter 5 Examples

• No measurement errors only modelling errors fitting a sine with a polynomial
• Measurement errors in X
• Measurement errors in y
The median absolute deviation to non corrupt new data is used to judge the quality of the prediction
What we can see that
• RANSAC is good for strong outliers in the y direction
• TheilSen is good for small outliers both in direction X and y but has a break point above which it performs worse than OLS
• The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect
•

51827 L1 Penalty and Sparsity in Logistic Regression
Comparison of the sparsity percentage of zero coefficients of solutions when L1 L2 and ElasticNet penalty are used for different values of C We can see that large values of C give more freedom to the model Conversely smaller values of C constrain the model more In the L1 penalty case this leads to sparser solutions As expected the ElasticNet penalty sparsity is between that of L1 and L2
We classify 8x8 images of digits into two classes 04 against 59 The visualization shows coefficients of the models for varying C

51829 Automatic Relevance Determination Regression ARD
Fit regression model with Bayesian Ridge Regression
SeeBayesian Ridge Regression for more information on the regressor
Compared to the OLS ordinary least squares estimator the coefficient weights are slightly shifted toward zeros
which stabilises them
The histogram of the estimated weights is very peaked as a sparsityinducing prior is implied on the weights
The estimation of the model is done by iteratively maximizing the marginal loglikelihood of the observations
We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expan
sion Note the uncertainty starts going up on the right side of the plot This is because these test samples are outside
of the range of the training samples

51831 Lasso model selection CrossValidation AIC BIC
Use the Akaike information criterion AIC the Bayes Information criterion BIC and crossvalidation to select an optimal value of the regularization parameter alpha of the Lasso estimator
Results obtained with LassoLarsIC are based on AICBIC criteria
Informationcriterion based model selection is very fast but it relies on a proper estimation of degrees of freedom are derived for large samples asymptotic results and assume the model is correct ie that the data are actually generated by this model They also tend to break when the problem is badly conditioned more features than samples
For crossvalidation we use 20fold with 2 algorithms to compute the Lasso path coordinate descent as implemented by the LassoCV class and Lars least angle regression as implemented by the LassoLarsCV class Both algorithms give roughly the same results They differ with regards to their execution speed and sources of numerical errors
Lars computes a path solution only for each kink in the path As a result it is very efficient when there are only of few kinks which is the case if there are few features or samples Also it is able to compute the full path without setting any meta parameter On the opposite coordinate descent compute the path points on a prespecified grid here we use the default Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount In terms of numerical errors for heavily correlated variables Lars will accumulate more errors while the coordinate descent algorithm will only sample the path on a grid
Note how the optimal value of alpha varies for each fold This illustrates why nestedcross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by crossvalidation this choice of parameter may not be optimal for unseen data

51832 Multiclass sparse logisitic regression on newgroups20
Comparison of multinomial logistic L1 vs oneversusrest L1 logistic regression to classify documents from the new groups20 dataset Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset
Here we use the l1 sparsity that trims the weights of not informative features to zero This is good if the goal is to extract the strongly discriminative vocabulary of each class If the goal is to get the best predictive accuracy it is better to use the non sparsityinducing l2 penalty instead

A more traditional and possibly better way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional l2penalised logistic regression model

51833 Early stopping of Stochastic Gradient Descent
Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion performing a gradient descent step sample by sample In particular it is a very efficient method to fit linear models As a stochastic method the loss function is not necessarily decreasing at each iteration and convergence is only guaranteed in expectation For this reason monitoring the convergence on the loss function can be difficult
Another approach is to monitor convergence on a validation score In this case the input data is split into a training set and a validation set The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of overfitting the training data
This early stopping strategy is activated if earlystoppingTrue otherwise the stopping criterion only uses the training loss on the entire input data To better control the early stopping strategy we can specify a parameter validationfraction which set the fraction of the input dataset that we keep aside to compute the validation score The optimization will continue until the validation score did not improve by at least tol during the last niternochange iterations The actual number of iterations is available at the attribute niter
This example illustrates how the early stopping can used in the sklearnlinearmodelSGDClassifier model to achieve almost the same accuracy as compared to a model built without early stopping This can significantly reduce training time Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion

5193 tSNE The effect of various perplexity values on the shape
An illustration of tSNE on the two concentric circles and the Scurve datasets for different perplexity values
We observe a tendency towards clearer shapes as the preplexity value increases
The size the distance and the shape of clusters may vary upon initialization perplexity values and does not always convey a meaning
As shown below tSNE for higher perplexities finds meaningful topology of two concentric circles however the size and the distance of the circles varies slightly from the original Contrary to the two circles dataset the shapes visually diverge from Scurve topology on the Scurve dataset even for larger perplexity values
For further details “How to Use tSNE Effectively” httpsdistillpub2016misreadtsne provides a good discussion of the effects of various parameters as well as interactive plots to explore those effects

5194 Comparison of Manifold Learning methods
An illustration of dimensionality reduction on the Scurve dataset with various manifold learning methods
For a discussion and comparison of these algorithms see the manifold module page
For a similar example where the methods are applied to a sphere dataset see Manifold Learning methods on a severed
sphere

Note that the purpose of the MDS is to find a lowdimensional representation of the data here 2D in which the distances respect well the distances in the original highdimensional space unlike other manifoldlearning algorithms it does not seeks an isotropic representation of the data in the lowdimensional space

5195 Manifold Learning methods on a severed sphere
An application of the different Manifold learning techniques on a spherical dataset Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods Regarding the dataset the poles are cut from the sphere as well as a thin slice down its side This enables the manifold learning techniques to ‘spread it open’ whilst projecting it onto two dimensions
For a similar example where the methods are applied to the Scurve dataset see Comparison of Manifold Learning methods
Note that the purpose of the MDS is to find a lowdimensional representation of the data here 2D in which the distances respect well the distances in the original highdimensional space unlike other manifoldlearning algorithms it does not seeks an isotropic representation of the data in the lowdimensional space Here the manifold problem matches fairly that of representing a flat map of the Earth as with map projection

5196 Manifold learning on handwritten digits Locally Linear Embedding
Isomap
An illustration of various embeddings on the digits dataset
1226 Chapter 5 Examples

The RandomTreesEmbedding from the sklearnensemble module is not technically a manifold embedding method as it learn a highdimensional representation on which we apply a dimensionality reduction method However it is often useful to cast a dataset into a representation in which the classes are linearlyseparable
tSNE will be initialized with the embedding that is generated by PCA in this example which is not the default setting It ensures global stability of the embedding ie the embedding does not depend on random initialization
Linear Discriminant Analysis from the sklearndiscriminantanalysis module and Neighborhood Com ponents Analysis from the sklearnneighbors module are supervised dimensionality reduction method ie they make use of the provided labels contrary to other methods

5202 Gaussian Mixture Model Ellipsoids
Plot the confidence ellipsoids of a mixture of two Gaussians obtained with Expectation Maximisation GaussianMixture class and Variational Inference BayesianGaussianMixture class models with a Dirichlet process prior
Both models have access to five components with which to fit the data Note that the Expectation Maximisation model will necessarily use all five components while the Variational Inference model will effectively only use as many as are needed for a good fit Here we can see that the Expectation Maximisation model splits some components arbitrarily because it is trying to fit too many components while the Dirichlet Process model adapts it number of state automatically
This example doesn’t show it as we’re in a lowdimensional space but another advantage of the Dirichlet process model is that it can fit full covariance matrices effectively even when there are less examples per cluster than there are dimensions in the data due to regularization properties of the inference algorithm

5203 Gaussian Mixture Model Selection
This example shows that model selection can be performed with Gaussian Mixture Models using informationtheoretic criteria BIC Model selection concerns both the covariance type and the number of components in the model In that case AIC also provides the right result not shown to save time but BIC is better suited if the problem is to identify the right model Unlike Bayesian procedures such inferences are priorfree
In that case the model with 2 components and full covariance which corresponds to the true generative model is selected

5204 GMM covariances
Demonstration of several covariances types for Gaussian mixture models
SeeGaussian mixture models for more information on the estimator
Although GMM are often used for clustering we can compare the obtained clusters with the actual classes from the dataset We initialize the means of the Gaussians with the means of the classes from the training set to make this comparison valid
We plot predicted labels on both training and held out test data using a variety of GMM covariance types on the iris dataset We compare GMMs with spherical diagonal full and tied covariance matrices in increasing order of performance Although one would expect full covariance to perform best in general it is prone to overfitting on small datasets and does not generalize well to held out test data
On the plots train data is shown as dots while test data is shown as crosses The iris dataset is fourdimensional Only the first two dimensions are shown here and thus some points are separated in other dimensions

5205 Gaussian Mixture Model Sine Curve
This example demonstrates the behavior of Gaussian mixture models fit on data that was not sampled from a mixture of Gaussian random variables The dataset is formed by 100 points loosely spaced following a noisy sine curve There is therefore no ground truth value for the number of Gaussian components
The first model is a classical Gaussian Mixture Model with 10 components fit with the ExpectationMaximization algorithm
The second model is a Bayesian Gaussian Mixture Model with a Dirichlet process prior fit with variational inference The low value of the concentration prior makes the model favor a lower number of active components This models “decides” to focus its modeling power on the big picture of the structure of the dataset groups of points with alternating directions modeled by nondiagonal covariance matrices Those alternating directions roughly capture the alternating nature of the original sine signal
The third model is also a Bayesian Gaussian mixture model with a Dirichlet process prior but this time the value of the concentration prior is higher giving the model more liberty to model the finegrained structure of the data The result is a mixture with a larger number of active components that is similar to the first model where we arbitrarily decided to fix the number of components to 10

Which model is the best is a matter of subjective judgement do we want to favor models that only capture the big picture to summarize and explain most of the structure of the data while ignoring the details or do we prefer models that closely follow the high density regions of the signal

The last two panels show how we can sample from the last two models The resulting samples distributions do not look exactly like the original data distribution The difference primarily stems from the approximation error we made by using a model that assumes that the data was generated by a finite number of Gaussian components instead of a continuous noisy sine curve

520 Gaussian Mixture Models 1257

scikitlearn user guide Release 0213
5206 Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture
This example plots the ellipsoids obtained from a toy dataset mixture of three Gaussians fit
ted by the BayesianGaussianMixture class models with a Dirichlet distribution prior
weightconcentrationpriortypedirichletdistribution and a Dirichlet process
prior weightconcentrationpriortypedirichletprocess On each figure we plot the
results for three different values of the weight concentration prior
TheBayesianGaussianMixture class can adapt its number of mixture components automatically The param
eterweightconcentrationprior has a direct link with the resulting number of components with nonzero
weights Specifying a low value for the concentration prior will make the model put most of the weight on few com
ponents set the remaining components weights very close to zero High values of the concentration prior will allow a
larger number of components to be active in the mixture
The Dirichlet process prior allows to define an infinite number of components and automatically selects the correct
number of components it activates a component only if it is necessary
On the contrary the classical finite mixture model with a Dirichlet distribution prior will favor more uniformly weighted
components and therefore tends to divide natural clusters into unnecessary subcomponents

5212 Plotting Validation Curves
In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma For very low values of gamma you can see that both the training score and the validation score are low This is called underfitting Medium values of gamma will result in high values for both scores ie the classifier is performing fairly well If gamma is too high the classifier will overfit which means that the training score is good but the validation score is poor

5213 Underfitting vs Overfitting
This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions The plot shows the function that we want to approximate which is a part of the cosine function In addition the samples from the real function and the approximations of different models are displayed The models have polynomial features of different degrees We can see that a linear function polynomial with degree 1 is not sufficient to fit the training samples This is called underfitting A polynomial of degree 4 approximates the true function almost perfectly However for higher degrees the model will overfit the training data ie it learns the noise of the training data We evaluate quantitatively overfitting underfitting by using crossvalidation We calculate the mean squared error MSE on the validation set the higher the less likely the model generalizes correctly from the training data

521 Model Selection 1265

5214 Parameter estimation using grid search with crossvalidation
This examples shows how a classifier is optimized by crossvalidation which is done using the sklearn modelselectionGridSearchCV object on a development set that comprises only half of the available labeled data
The performance of the selected hyperparameters and trained model is then measured on a dedicated evaluation set that was not used during the model selection step
More details on tools available for model selection can be found in the sections on Crossvalidation evaluating estimator performance andTuning the hyperparameters of an estimator

scikitlearn user guide Release 0213
5215 Train error vs Test error
Illustration of how the performance of an estimator on unseen data test data is not the same as the performance on training data As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter The example with an ElasticNet regression model and the performance is measured using the explained variance aka R2

scikitlearn user guide Release 0213
5216 Receiver Operating Characteristic ROC with cross validation
Example of Receiver Operating Characteristic ROC metric to evaluate classifier output quality using crossvalidation
ROC curves typically feature true positive rate on the Y axis and false positive rate on the X axis This means that the top left corner of the plot is the “ideal” point a false positive rate of zero and a true positive rate of one This is not very realistic but it does mean that a larger area under the curve AUC is usually better
The “steepness” of ROC curves is also important since it is ideal to maximize the true positive rate while minimizing the false positive rate
This example shows the ROC response of different datasets created from Kfold crossvalidation Taking all of these curves it is possible to calculate the mean area under curve and see the variance of the curve when the training set is split into different subsets This roughly shows how the classifier output is affected by changes in the training data and how different the splits generated by Kfold crossvalidation are from one another
Note

5217 Comparing randomized search and grid search for hyperparameter estima
tion
Compare randomized search and grid search for optimizing hyperparameters of a random forest All parameters that influence the learning are searched simultaneously except for the number of estimators which poses a time quality tradeoff
The randomized search and the grid search explore exactly the same space of parameters The result in parameter settings is quite similar while the run time for randomized search is drastically lower
The performance is slightly worse for the randomized search though this is most likely a noise effect and would not carry over to a heldout test set
Note that in practice one would not search over this many different parameters simultaneously using grid search but pick only the ones deemed most important

5218 Nested versus nonnested crossvalidation
This example compares nonnested and nested crossvalidation strategies on a classifier of the iris data set Nested
crossvalidation CV is often used to train a model in which hyperparameters also need to be optimized Nested CV
estimates the generalization error of the underlying model and its hyperparameter search Choosing the parameters
that maximize nonnested CV biases the model to the dataset yielding an overlyoptimistic score
Model selection without nested CV uses the same data to tune model parameters and evaluate model performance
Information may thus “leak” into the model and overfit the data The magnitude of this effect is primarily dependent
on the size of the dataset and the stability of the model See Cawley and Talbot1for an analysis of these issues
To avoid this problem nested CV effectively uses a series of trainvalidationtest set splits In the inner loop
here executed by GridSearchCV the score is approximately maximized by fitting a model to each training
set and then directly maximized in selecting hyperparameters over the validation set In the outer loop here in
crossvalscore generalization error is estimated by averaging test set scores over several dataset splits
The example below uses a support vector classifier with a nonlinear kernel to build a model with optimized hyperpa
rameters by grid search We compare the performance of nonnested and nested CV strategies by taking the difference
between their scores

52112 Confusion matrix
Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set The diagonal elements represent the number of points for which the predicted label is equal to the true label while offdiagonal elements are those that are mislabeled by the classifier The higher the diagonal values of the confusion matrix the better indicating many correct predictions
The figures show the confusion matrix with and without normalization by class support size number of elements in

each class This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best In real life applications this parameter is usually chosen using Tuning the hyperparameters of an estimator

52113 Visualizing crossvalidation behavior in scikitlearn
Choosing the right crossvalidation object is a crucial part of fitting a model properly There are many ways to split data into training and test sets in order to avoid model overfitting to standardize the number of groups in test sets etc
This example visualizes the behavior of several common scikitlearn objects for comparison
from sklearnmodelselection import TimeSeriesSplit KFold ShuffleSplit StratifiedKFold GroupShuffleSplit GroupKFold StratifiedShuffleSplit
import numpy as np
import matplotlibpyplot as plt
from matplotlibpatches import Patch
nprandomseed1338
cmapdata pltcmPaired

nsplits 4
Visualize our data
First we must understand the structure of our data It has 100 randomly generated input datapoints 3 classes split unevenly across datapoints and 10 “groups” split evenly across datapoints
As we’ll see some crossvalidation objects do specific things with labeled data others behave differently with grouped data and others do not use this information
To begin we’ll visualize our data

Let’s see how it looks for the KFold crossvalidation object
fig ax pltsubplots
cv KFoldnsplits
plotcvindicescv X y groups ax nsplits

As you can see by default the KFold crossvalidation iterator does not take either datapoint class or group into consideration We can change this by using the StratifiedKFold like so

```
fig ax  pltsubplots
cv  StratifiedKFoldnsplits
plotcvindicescv X y groups ax nsplits
```

scikitlearn user guide Release 0213
In this case the crossvalidation retained the same ratio of classes across each CV split Next we’ll visualize this behavior for a number of CV iterators
Visualize crossvalidation indices for many CV objects
Let’s visually compare the cross validation behavior for many scikitlearn crossvalidation objects Below we will loop through several common crossvalidation objects visualizing the behavior of each
Note how some use the groupclass information while others do not

52114 Receiver Operating Characteristic ROC
Example of Receiver Operating Characteristic ROC metric to evaluate classifier output quality
ROC curves typically feature true positive rate on the Y axis and false positive rate on the X axis This means that the top left corner of the plot is the “ideal” point a false positive rate of zero and a true positive rate of one This is not very realistic but it does mean that a larger area under the curve AUC is usually better
The “steepness” of ROC curves is also important since it is ideal to maximize the true positive rate while minimizing the false positive rate
Multiclass settings
ROC curves are typically used in binary classification to study the output of a classifier In order to extend ROC curve and ROC area to multiclass or multilabel classification it is necessary to binarize the output One ROC curve can be drawn per label but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction microaveraging
Another evaluation measure for multiclass classification is macroaveraging which gives equal weight to the classi fication of each label

52115 Plotting Learning Curves
On the left side the learning curve of a naive Bayes classifier is shown for the digits dataset Note that the training score and the crossvalidation score are both not very good at the end However the shape of the curve can be found in more complex datasets very often the training score is very high at the beginning and decreases and the cross validation score is very low at the beginning and increases On the right side we see the learning curve of an SVM with RBF kernel We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples

Generate a simple plot of the test and training learning curve
Parameters

estimator object type that implements the fit and predict methods
An object of that type which is cloned for each validation
title string
Title for the chart
X arraylike shape nsamples nfeatures
Training vector where nsamples is the number of samples and
nfeatures is the number of features

y arraylike shape nsamples or nsamples nfeatures optional
Target relative to X for classification or regression
None for unsupervised learning
ylim tuple shape ymin ymax optional
Defines minimum and maximum yvalues plotted
cv int crossvalidation generator or an iterable optional
Determines the crossvalidation splitting strategy
Possible inputs for cv are
 None to use the default 3fold crossvalidation
 integer to specify the number of folds
 termCV splitter
 An iterable yielding train test splits as arrays of indices
For integerNone inputs if y is binary or multiclass
classStratifiedKFold used If the estimator is not a classifier
or if y is neither binary nor multiclass classKFold is used
Refer refUser Guide crossvalidation for the various
crossvalidators that can be used here
njobs int or None optional defaultNone
Number of jobs to run in parallel
None means 1 unless in a objjoblibparallelbackend context
1 means using all processors See termGlossary njobs
for more details
trainsizes arraylike shape nticks dtype float or int
Relative or absolute numbers of training examples that will be used to
generate the learning curve If the dtype is float it is regarded as a
fraction of the maximum size of the training set that is determined
by the selected validation method ie it has to be within 0 1
Otherwise it is interpreted as absolute sizes of the training sets
Note that for classification the number of samples usually have to
be big enough to contain at least one sample from each class

52116 PrecisionRecall
Example of PrecisionRecall metric to evaluate classifier output quality
PrecisionRecall is a useful measure of success of prediction when the classes are very imbalanced In information retrieval precision is a measure of result relevancy while recall is a measure of how many truly relevant results are returned
The precisionrecall curve shows the tradeoff between precision and recall for different threshold A high area under the curve represents both high recall and high precision where high precision relates to a low false positive rate and high recall relates to a low false negative rate High scores for both show that the classifier is returning accurate results high precision as well as returning a majority of all positive results high recall
A system with high recall but low precision returns many results but most of its predicted labels are incorrect when compared to the training labels A system with high precision but low recall is just the opposite returning very few results but most of its predicted labels are correct when compared to the training labels An ideal system with high precision and high recall will return many results with all results labeled correctly
Precision □ is defined as the number of true positives □□ over the number of true positives plus the number of false positives □□
□□□
□□□□
1304 Chapter 5 Examples

Recall □ is defined as the number of true positives □□ over the number of true positives plus the number of false negatives □□
□□□
□□□□
These quantities are also related to the □1 score which is defined as the harmonic mean of precision and recall
□1 2□×□
□□
Note that the precision may not decrease with recall The definition of precision □□
□□□□ shows that lowering the
threshold of a classifier may increase the denominator by increasing the number of results returned If the threshold was previously set too high the new results may all be true positives which will increase precision If the previous threshold was about right or too low further lowering the threshold will introduce false positives decreasing precision
Recall is defined as□□
□□□□ where □□□□does not depend on the classifier threshold This means that lowering
the classifier threshold may increase recall by increasing the number of true positive results It is also possible that lowering the threshold may leave recall unchanged while the precision fluctuates
The relationship between recall and precision can be observed in the stairstep area of the plot at the edges of these steps a small change in the threshold considerably reduces precision with only a minor gain in recall
Average precision AP summarizes such a plot as the weighted mean of precisions achieved at each threshold with the increase in recall from the previous threshold used as the weight
AP∑
□□□−□□−1□□
where □□and□□are the precision and recall at the nth threshold A pair □□ □□is referred to as an operating point
AP and the trapezoidal area under the operating points sklearnmetricsauc are common ways to summarize a precisionrecall curve that lead to different results Read more in the User Guide
Precisionrecall curves are typically used in binary classification to study the output of a classifier In order to extend the precisionrecall curve and average precision to multiclass or multilabel classification it is necessary to binarize the output One curve can be drawn per label but one can also draw a precisionrecall curve by considering each element of the label indicator matrix as a binary prediction microaveraging

5221 Classifier Chain
Example of using classifier chain on a multilabel dataset
For this example we will use the yeast dataset which contains 2417 datapoints each with 103 features and 14 possible labels Each data point has at least one label As a baseline we first train a logistic regression classifier for each of the 14 labels To evaluate the performance of these classifiers we predict on a heldout test set and calculate the jaccard score for each sample
Next we create 10 classifier chains Each classifier chain contains a logistic regression model for each of the 14 labels The models in each chain are ordered randomly In addition to the 103 features in the dataset each model gets the predictions of the preceding models in the chain as features note that by default at training time each model gets the true labels as features These additional features allow each chain to exploit correlations among the classes The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models
Because the models in each chain are arranged randomly there is significant variation in performance among the chains Presumably there is an optimal ordering of the classes in a chain that will yield the best performance However we do not know that ordering a priori Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 05 The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble although this is not guaranteed with randomly ordered chains

5232 Outlier detection with Local Outlier Factor LOF
The Local Outlier Factor LOF algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors It considers as outliers the samples that have a substantially lower density than their neighbors This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikitlearn Note that when LOF is used for outlier detection it has no predict decisionfunction and scoresamples methods See User Guide for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection
The number of neighbors considered parameter nneighbors is typically set 1 greater than the minimum number of samples a cluster has to contain so that other samples can be local outliers relative to this cluster and 2 smaller than the maximum number of close by samples that can potentially be local outliers In practice such informations are generally not available and taking nneighbors20 appears to work well in general

5236 Novelty detection with Local Outlier Factor LOF
The Local Outlier Factor LOF algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors It considers as outliers the samples that have a substantially lower density than their neighbors This example shows how to use LOF for novelty detection Note that when LOF is used for novelty detection you MUST not use predict decisionfunction and scoresamples on the training set as this would lead to wrong results You must only use these methods on new unseen data which are not in the training set See User Guide for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection
The number of neighbors considered parameter nneighbors is typically set 1 greater than the minimum number of samples a cluster has to contain so that other samples can be local outliers relative to this cluster and 2 smaller than the maximum number of close by samples that can potentially be local outliers In practice such informations are generally not available and taking nneighbors20 appears to work well in general

```
import numpy as np
import matplotlib
import matplotlibpyplot as plt
from sklearnneighbors import LocalOutlierFactor
printdoc
nprandomseed42
xx yy  npmeshgridnplinspace5 5 500 nplinspace5 5 500
 Generate normal not abnormal training observations
X  03 nprandomrandn100 2
Xtrain  nprX  2 X  2
 Generate new normal not abnormal observations
X  03 nprandomrandn20 2
Xtest  nprX  2 X  2
 Generate some abnormal novel observations
Xoutliers  nprandomuniformlow4 high4 size20 2
 fit the model for novelty detection noveltyTrue
clf  LocalOutlierFactornneighbors20 noveltyTrue contamination01
clffitXtrain
 DO NOT use predict decisionfunction and scoresamples on Xtrain as this
 would give wrong results but only on new unseen data not used in Xtrain
 eg Xtest Xoutliers or the meshgrid
ypredtest  clfpredictXtest
```
